CHAPTER 32

# LICENSE/WAIVER

These materials are made available under the terms of Creative Commons 0 copyright waiver instead of a "traditional" copyleft license. We the undersigned agree to the following, wherein "this work" refers to "The Peeragogy Handbook" and all other content posted on peeragogy.org or the original collaboratory site, `http://socialmediaclassroom.com/host/peeragogy`.

**I hereby waive all copyright and related or neighboring rights together with all associated claims and causes of action with respect to this work to the extent possible under the law.**

Signed:

*Bryan Alexander, Paul Allison, Elisa Armendáriz, Régis Barondeau, Doug Breitbart, George Brett, Suz Burroughs, Joseph Corneli, Jay Cross, Charles Jeffrey Danoff, Julian Elve, María Fernanda Arenas, James Folkestad, John Graves, Kathy Gill, Matthew Herschler, Gigi Johnson, Anna Keune, John Laing, Kyle Larson, Roland Legrand, Amanda Lyons, Dorotea Mar, Christopher Tillman Neal, Ted Newcomb, Stephanie Parker, Miguel Ángel Pérez Álvarez, Charlotte Pierce, David Preston, Howard Rheingold, Paola Ricaurte, Laura Ritchie, Verena Roberts, Stephanie Schipper, Lisa Snow MacDonald, Fabrizio Terzi, and Geoff Walker*

Note that this waiver does not apply to other works by the above authors, including works linked to from peeragogy.org.

Future contributors: Note also that we will require a similar copyright waiver agreement in order to add content that others can reuse. That said, the waiver also means that you are free to do essentially whatever you like with the content in your own work! Have fun!

### How we came to this decision

These Creative Commons license options were proposed by various members of the community:

- *CC Zero* - public domain; no restrictions for downstream users
- *CC By-SA* - requires downstream users to include attribution and to license their work in the same way
- *CC By-SA-NC* - requires downstream users to include attribution, to license their work in the same way and disallows any commercial use of the content

After a brief discussion, no one was in favor of restricting downstream users, so we decided to go with CC0. We agreed that we would get enough "credit" by having our names on peeragogy.org. In connection with this discussion, we agreed that we would work on ways to explicitly build "reusability" into the handbook content.

# Towards generating novel games using conceptual blending

**Jeremy Gow** and **Joseph Corneli**
Computational Creativity Group
Department of Computing
Goldsmiths, University of London, UK

**Abstract**

We sketch the process of creating a novel video game by blending two video games specified in the Video Game Description Language (VGDL), following the COINVENT computational model of conceptual blending. We highlight the choices that need to be made in this process, and discuss the prospects for a computational game designer based on blending.

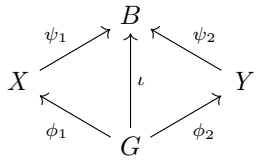
## Introduction

This paper outlines the process of creating a novel video game by blending two video game descriptions given in the Video Game Description Language (VGDL). Several issues need to be considered: which games to blend? Which elements of the game will be blended and which removed? Do we need to adjust the resulting game in order to make it playable? Taking two games from the GVG-AI Competition (Perez et al. 2015), we provide a worked example based on a recent computational, domain-independant model of conceptual blending (Bou et al. 2015).

Our account provides a high-level sketch of how a computational system could blend game designs, and does not propose a concrete architecture. Instead, our intent is explore how a game blending system could work. We highlight the specific challenges presented by various steps in the blending process, and describe how certain steps provide the opportunity to add or close off new potential mechanics and meanings. The implementation and evaluation of this approach will be the focus of future work.

## Background

Recent research (Treanor et al. 2012; Cook and Colton 2014) has examined computational generation of games from provided concepts. The current exploration of blending game descriptions is motivated by our observation that game designers often build new games by combining ideas from existing games.



Conceptual blending is the notion that new concepts can be generated by combining elements of existing concepts. **COINVENT** is an EU FP7 project that aims to develop a "computationally feasible, formal model of conceptual blending" (Schorlemmer et al. 2014)[1]. The project takes Goguen's formalisation of conceptual blending as a starting point (Goguen 1999). Early implementations draw on the related notion of amalgams (Ontañón and Plaza 2010). The core ideas in the model are:

**Conceptual spaces** may be mathematical theories, ontologies, or, in our case, video game descriptions.

**Signature morphisms** between conceptual spaces are mappings from the symbols of a source conceptual space into the symbols of target conceptual space. In the diagram below, $\phi_1$, $\phi_2$, $\psi_1$, $\psi_2$, and $\iota$ are all signature morphisms.

**Generic spaces** are a particular kind of conceptual space that possess maximum commonality with a number of given input spaces. In the diagram below, $\phi_1$ and $\phi_2$ represent the inclusion of the elements of the generic space $G$ in both $X$ and $Y$.

**Blends** are unique conceptual spaces that preserve structure from the input spaces and a generic space $G$, via a specific arrangement of signature morphisms; namely, such that the diagram is commutative, and that 'axioms' in the input spaces $X, Y$ are sent to 'theorems' in the unique colimit $B$, known as *the blend*:

Within the COINVENT project the model has been primarily applied to examples from mathematics (Bou et al. 2015) and music (Cambouropoulos, Kaliakatsos-Papakostas, and Tsougras 2014). The constituent processes have been automated to differing degrees, and for some simple examples complete automation is feasible. One of the key outstanding issues is the evaluation of blends, both from the point of view of judging the final outcome, and from an 'online' point of view that can help constrain the potential combinatorial explosion as the collection of possible input spaces is explored, and possible blends are computed.

**VGDL:** The Video Game Description Language allows the specification of simple arcade-style games (Schaul 2014). It was recently developed to support research into artificial intelligence and games, in particular general game-playing agents, and now forms the basis of the General Video Game Playing AI (GVG-AI) Competition (Perez et al. 2015).

VGDL conceptualises a game as having five components:

**Sprite Set** The entities in the game, their types and properties. The predefined types are Avatar, FromAvatar, NPC, Static, Movable, Resource and Portal, plus a large number of specialised subtypes, e.g. RandomNPC. The sprites are arranged in a hierarchy, where subsprites (here denoted $\sqsubseteq$) inherit types/properties of their ancestors.

**Interaction Set** The mechanics of the game. Each interaction rule defines the consequences of a particular pair of sprites overlapping.

**Termination Set** The win/lose conditions, based on either a timeout or the value of counter, e.g. player health.

**Level Mapping** A translation from ASCII characters to sprites.

**Level Designs** Multiple levels can be defined in ASCII, interpreted using the Level Mapping.

A VGDL specification defines the first four elements, with level designs being specified in a set of accompanying text files.

The sprites and rules are described in terms of a predefined ontology, e.g. a sprite can be a RandomNPC which wanders around the screen. The default ontology is fairly limited, and the VGDL versions of well-known titles are often quite simplistic. Nevertheless, it can be used to define an impressive range of games which present a serious challenge for a general game-playing agent, as demonstrated by the GVG Competition examples. In the context of game design, VGDL presents a large space of possible games. Random instances from within that space are unlikely to be coherant, playable games, let alone high quality ones (Barros and Togelius 2014). Hence it also presents a research challenge for automated game design, and researchers are now beginning to look at VGDL generation (Nielsen et al. 2015b).

## Blending VGDL

Taking VGDL specifications as our 'conceptual spaces' for games, we wish to show how a computational agent could conceivably create new designs by blending existing game elements. Our proposed approach closely follows the general COINVENT process model:

**Select** two input games to blend.

**Generalise** the games by matching selected elements from each, resulting in a *generic game concept*.

**Blend** the games by combining their constituent elements, reformulated in terms of the generic game concept.

**Evaluate** whether the (perhaps nonsensical) blend is a viable game.

**Weaken** the blend by removing/adjusting elements to achieve viability.

**Run** the blend by elaborating the design to exploit any new structure which it has introduced.

The following account is a thought experiment, but is, we argue, computationally plausible. We expect that the majority of games developed by such a process would not be playable, and indeed there will be many partially developed blends that will fail. For non-trivial examples, each stage presents a huge number of choices — a combinatorial explosion which any automated designer needs to tackle in order to extract playable needles out of a haystack of 'frankengames'. We draw attention below to some of the decisions a computational designer would have to confront.

The term "designer" is used to refer to this imagined agent, but one might also conceive a co-creative approach where a human designer takes some of the key decisions, and perhaps takes inspiration from the blends the system produces.

Previous work in automated game design has suggested that there are few intrinsic criteria for game quality (Nelson et al. 2015). Playtesting, whether by humans or bots, is an essential component of game design. An implementation could use feedback from automated playtesting of the games to guide this process, as in e.g. (Nielsen et al. 2015a; 2015b).

We completely sidestep the difficult issues of blending level designs and blending audiovisual elements, focusing instead on blending game entities and rules. Of course, the design of all these elements is intimitely connected, and a full account of game blending would encompass these as well.

### Selection

The first question is which games *should* we blend? Input game selection can be thought of as taking part in some wider game design context: perhaps an agent is elaborating a particular design, and decides to blend in another game concept in order to fix a perceived problem with the original. Alternatively, an agent could be simply exploring the creative possibilities of mashing together diverse game designs.

For this paper, we have just hand-selected two games from the GVG Competition example set: *Frogger* (AKA *Frogs*) and *Zelda* (Perez et al. 2015). Both games are inspired by well-known commercial titles and have simple specifications — the VGDL is shown in Figure 1 and 2 respectively. The level and visual design are both outside the scope of this paper, so for simplicity we have omitted the `LevelMapping` information and `img` and `color` properties. We have also renamed a few sprites and made minor alterations for clarity, without affecting the game mechanics.

It is possible to intuit a lot about how these games work from the VGDL descriptions: the player controls an Avatar, Missiles travel in given direction etc. Due to lack of space, we do not include a full description of the games: see Schaul (2014) for more details, or play

```
SpriteSet
  forest > SpawnPoint stype=log
    dense > prob=0.4 cooldown=10
      sparse > prob=0.1 cooldown=5
  structure > Immovable
      home > Door
      water
      wall
  log > Missile orientation=LEFT speed=0.1
  safety > Resource limit=2
  frog > MovingAvatar
  truck > Missile img=truck
      rightTruck > orientation=RIGHT
          fastRtruck > speed=0.2
          slowRtruck > speed=0.1
      leftTruck > orientation=LEFT
          fastLtruck > speed=0.2
          slowLtruck > speed=0.1

InteractionSet
  home frog  > killSprite scoreChange=1
  frog log   > changeResource resource=safety value=2
  frog log   > pullWithIt
  frog wall  > stepBack
  frog water > killIfHasLess resource=safety limit=0
  frog water > changeResource resource=safety value=-1
  frog truck > killSprite scoreChange=-2
  log   EOS  > killSprite
  truck EOS  > wrapAround

TerminationSet
  SpriteCounter stype=home win=True
  SpriteCounter stype=frog win=False
```

them using the Java emulator at `https://github.com/EssexUniversityMCTS/gvgai`.

## Generalisation

The generalisation step proposes a *generic game concept* which can be mapped onto elements of the two input games. In the case of VGDL, we need to propose one or more generic sprites, which can then be mapped on to a subset of the two input sprite sets. For example, if game $X$ features *aliens* and game $Y$ *ghosts*, we could propose a generic game concept $G$ with *enemies*. We then have two *signature morphisms*, i.e. mappings from the sprites of $G$ to the sprites of the input games: $\phi(G, X) : enemy \mapsto alien$ and $\phi(G, Y) : enemy \mapsto ghost$.

Even for quite small sprite sets the number of possible mappings is considerable. We can imagine quite radical mappings, e.g. where a sprite is mapped to both the player avatar and a ghost, or both an alien and an ammo pack, and these clearly have a lot of creative potential. However, for now we make the additional simplifying assumption that the mappings preserve the VGDL sprite categories: Avatar, NPC, Resource etc. So the generic player avatar is mapped to the player avatars in both input games, and so on.

In our running example, the designer could propose the following category-preserving generic sprite set that maps

```
SpriteSet
  door > Door
  key > Immovable
  wall > Immovable
  sword > Flicker limit=5 singleton=True
  movable >
      link > ShootAvatar stype=sword
          nokey
          withkey
      monster > RandomNPC
          monsterQuick > cooldown=2
          monsterNormal > cooldown=4
          monsterSlow > cooldown=8

InteractionSet
  movable wall  > stepBack
  nokey door    > stepBack
  door withkey  > killSprite scoreChange=1
  monster sword > killSprite scoreChange=2
  link monster  > killSprite scoreChange=-1
  key link      > killSprite scoreChange=1
  nokey key     > transformTo stype=withkey

TerminationSet
  SpriteCounter stype=door win=True
  SpriteCounter stype=link win=False
```

Figure 2: *Zelda* VGDL specification.

as follows:

| Generic | Frogger | Zelda |
|---|---|---|
| avatar | frog | link |
| goal | home | door |
| wall | wall | wall |
| enemy | truck | monster |
| fastREnemy | fastRTruck | monsterQuick |
| fastLEnemy | fastLTruck | monsterQuick |
| slowREnemy | slowRTruck | monsterSlow |
| slowLEnemy | slowLTruck | monsterSlow |

Note that both input games have additional unmapped sprites, e.g. *Zelda*'s `key` and `sword` don't correspond to anything in the generic game.

## Blending the Sprites

An initial version of our blended game — let's call it *Frolda* — can now be generated. The blended sprite set combines those from both games, merging sprites identified by the signature morphisms: this is shown in Figure 3.

In generating this blend, we have retained as much structure as possible from both games: `goal`$\sqsubseteq$`structure` is based on the `door` from *Zelda*, and the `monster` and `truck` sprite hierarchies have been integrated, retaining the `rightTruck` and `leftTruck` sprites from *Frogger* (renamed `rightEnemy` and `leftEnemy`).

The input games used two separate mechanisms to control NPC speed — `cooldown` (rate of action) and `speed` (distance traveled per movement action) — hence all enemies are slower in the blend than either of the inputs. This is an example of a undesirable interaction between game el-

```
forest > SpawnPoint stype=log
   dense > prob=0.4 cooldown=10
   sparse > prob=0.1 cooldown=5
structure > Immovable
   goal > Door
   water
   wall
   key
sword > Flicker limit=5 singleton=True
log > Missile orientation=LEFT speed=0.1
safety > Resource limit=2
movable >
   avatar > ShootAvatar stype=sword
      nokey
      withkey
   enemy > Missile
      rightEnemy > orientation=RIGHT
         fastREnemy > cooldown=2 speed=0.2
         slowREnemy > cooldown=8 speed=0.1
      leftEnemy > orientation=LEFT
         fastLEnemy > cooldown=2 speed=0.2
         slowLEnemy > cooldown=8 speed=0.1
   monsterNormal > RandomNPC cooldown=4
```

Figure 3: Initial sprite set for *Frolda*.

ements that will need to be dealt with later in the blending process.

Two significant decisions have been made during the sprite set blend:

1. The player is a `ShootAvatar`, following *Zelda*.
2. An `enemy` is a `Missile`, following *Frogger*.

This is a form of weakening (see below) which it makes sense to apply at this stage, adjusting the blend to ensure the initial blend is valid VGDL.

Some elements of the input games are unaffected by the blend: the walls, the river system from *Frogger* (`forest/water/log/safety`), and the `sword`, `key` and `monsterNormal` from *Zelda*.

## Blending the Rules

We continue the blend by combining the interaction sets: an initial version is shown in Figure 4. All interactions can be included without modification, except for `avatar-enemy`, which reduces the score by 2 in *Frogger*, but only 1 in *Zelda*. By choosing the latter value we again weaken the blend in order to obtain valid VGDL.

Finally, we blend the termination sets. In this example, the structure happens to be identical: the player loses if the avatar is killed, and wins if the goal is 'killed' by being touched by the avatar.

## Evaluation/Weakening

The initial blend includes all the sprites, interactions and termination conditions from both games, with a unique blended structure defined by the chosen signature morphisms. Adjustments were made to the blend to ensure we had valid VGDL, which introduced choices about how the unique blend should be weakened. The next step is to consider

```
goal avatar  > killSprite scoreChange=1
goal withkey > killSprite scoreChange=1
nokey goal   > stepBack
key avatar   > killSprite scoreChange=1
nokey key    > transformTo stype=withkey

movable wall > stepBack
avatar wall  > stepBack
avatar log   > changeResource resource=safety value=2
avatar log   > pullWithIt
avatar water > killIfHasLess resource=safety limit=0
avatar water > changeResource resource=safety value=-1
log   EOS    > killSprite
enemy EOS    > wrapAround

enemy sword  > killSprite scoreChange=2
avatar enemy > killSprite scoreChange=-1
monsterNormal sword  > killSprite scoreChange=2
avatar monsterNormal > killSprite scoreChange=-1
```

Figure 4: Initial interaction set for *Frolda*

whether we need to further weaken the blend to improve the game's coherance and playability.

First, we can see that the initial interaction set (see Figure 4) contains some redundancies:

- `avatar` and `movable` have the same interaction with `wall`, and `avatar`$\sqsubseteq$`movable`. Also note that `truck`$\sqsubseteq$`movable` and if trucks are blocked by walls then they will be prevented from wrapping around, i.e. all the trucks will end up stacked against the wall. Hence, we remove the `movable` interaction and retain the more specific rule.
- `avatar` and `withkey` have the same interaction with `goal`, and `withkey`$\sqsubseteq$`avatar`. If we retain the more general rule then the player could always get to the goal, making the key redundant. Hence we again choose to retain the more specific rule, and drop the `avatar` interaction.

Another principle we can apply is parsimony: does the game contain unnecessary elements? This is very much context-dependent. A designer who was working on *Frogger*, but had blended it with *Zelda* in order to add a key- door mechanism might regard the wandering `monsterNormal` as an unnecessary addition. Likewise, a *Zelda* designer who had blended in the 'crossing the road' structure from *Frogger* could regard the log/river system as unwanted. If we are interested in mashing up the two games, we could regard any additional structure outside the core of the blend (i.e. the generic shared structure) as unnecessary. Here we adopt the latter position, and remove both the wandering monsters (`monsterNormal`) and river system.

Finally, we may wish to retune values in the blended game, such as the speed of the enemies, which may not be appropriate in their new context. As noted above, the enemies speed in the initial blend is being modulated by both `speed` and `cooldown` values. Here, we decide that we can use the default `cooldown` value.

A final version of *Frolda* is shown in Figure 5. The game

```
SpriteSet
  structure > Immovable
      goal  > Door
      wall
      key
  sword > Flicker limit=5 singleton=True
  movable >
    avatar  > ShootAvatar stype=sword
      nokey
      withkey
    enemy > Missile
      rightEnemy > orientation=RIGHT
        fastREnemy > speed=0.2
        slowREnemy > speed=0.1
      leftEnemy > orientation=LEFT
        fastLEnemy > speed=0.2
        slowLEnemy > speed=0.1

InteractionSet
  goal withkey > killSprite scoreChange=1
  nokey goal   > stepBack
  key  avatar  > killSprite scoreChange=1
  nokey key    > transformTo stype=withkey
  avatar wall  > stepBack
  avatar enemy > killSprite scoreChange=-1
  enemy EOS    > wrapAround
  enemy sword  > killSprite scoreChange=2

TerminationSet
  SpriteCounter stype=goal   win=True
  SpriteCounter stype=avatar win=False
```

Figure 5: Final specification for *Frolda*.

features enemies that move laterally left and right across the screen, but which can be killed by using a sword, and requires the player to collect the key before reaching the goal. Figure 6 shows the game running in the GVG-AI Java emulator, with our choice of sprite images and level design. This level takes advantage of the key-door mechanic to force Frolda to cross the 'road' of monsters twice before exiting the level.

'Running the blend' refers to further elaborating the blended game to take advantage of the synthesis of game elements. For example, we may decide to make the `key` a Missile so that as well as 'crossing the road' of enemies, the player has to pick the key out of the moving traffic.

## Alternative Blends

One can imagine many alternative choices to the ones made above. Consider these examples, out of the many possible blends:

- A generic game which doesn't distinguish the speed of enemies, resulting in single-speed monsters which travel left and right.
- A generic game without a unified class of enemies. Trucks and monsters would both be included in the blend as a separate sprites, and the designer could run the blend by inventing new interactions for them.
- Blending `home` with `door`$\sqsubseteq$`structure` was straightforward. But what if *Frogger* had specified `home`$\sqsubseteq$`building`? One option would be to blend `building` and `structure` during the generalisation phase. Another would be to create a new relationship in the blend, e.g. `building`$\sqsubseteq$`structure`. A third option would be to remove, say, `building` entirely.
- When blending the sprite set we could have selected `MoveAvatar` instead of `ShootAvatar`, leaving the sword without a role in the game, to be later removed during weakening.
- Choosing `RandomNPC` enemies instead of `Missile` would have given us a *Zelda*-style free-roaming monsters instead of the horizontally-moving trucks that can be used in level designs to create a dangerous 'road'.

## Next Steps

The account above has glossed over many details, although we hope that each step is computationally plausible. Towards this end we intend to implement a basic VGDL blender using the Java VGDL library (Perez et al. 2015). We envision the primary research topic for blended games to surround *experimentation with heuristics*: can we manage the massive combinatorial possibilities to produce a diverse range of non-trivial, coherent, novel, playable games? A subsequent phase of work would integrate the implementation with the COINVENT software stack, as that matures. The COINVENT system currently accepts input in the Web Ontology Language (OWL) or the Common Algebraic Specification Language (CASL), so one likely approach would be to write a translator, for instance between VGDL descriptions and OWL.

A more immediate next step to support system-building is to work out further compelling examples in detail, e.g.

**Pac-Man + Zombies** The *Survive Zombies* game that ships with the GVG-AI collection has some similarity to *Pac-Man* (Perez et al. 2015). Both games give the protagonist the task of collecting a certain resource while avoiding a population of `Chasers`. However, in *Survive Zombies* another sprite is introduced (bees) which transforms the chasers into honey. One possible blend with *Pac-Man* would allow the protagonist to place fruit that is toxic to ghosts in strategic locations.

**Sokoban + Snake** The protagonist's tail grows when boxes are pushed to the goal[2].

**Sokoban + Sokoban** Two copies of *Sokoban* hooked together, so that boxes cleared from one side appear on the other. Perhaps best conceived of as a two-player game, with each player in the role of "Maxwell's demon". VGDL would have to be extended to multi-player games.

Two other directions that we did not address here include *level design* and *audiovisual design* for games. Rather than directly blending the example levels that accompany

[2]It seems challenging to implement Snake in VGDL, since the snake's tail would have to be made of a chain of `chasers` that are programmed to follow each other.

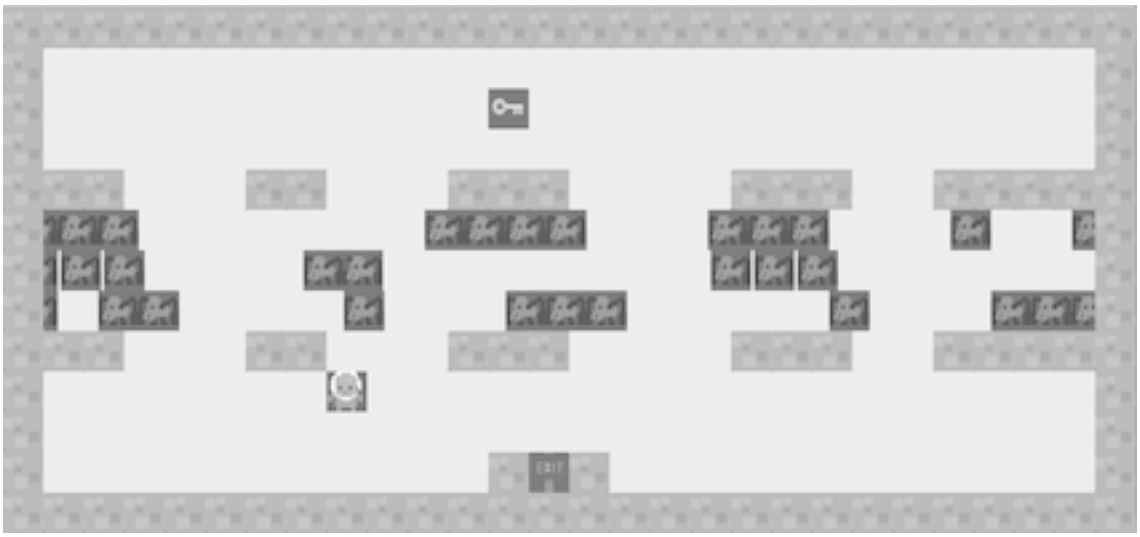

Figure 6: A screenshot of *Frolda* running in the GVG-AI Java emulator. The player (bottom left) has to cross the 'road' of monsters to get the key (top) and then cross again before exiting the level (bottom).

VGDL, we propose to express the *level idiom* in the form of a declarative level generator, e.g. in ASP (Smith and Mateas 2011), and blend these generators in concert with the rest of game description. Other aspects of visual design (e.g. sprites) could be developed through blending, building on recent work in icon blending (Confalonieri et al. 2015). Given its focus on game-playing agents, VGDL does not currently support any audio that could be blended, although it would be relatively easy to extend with simple audio effects to support research in that direction.

## Discussion

One aspect in which our account is significantly lacking is how a computational designer can "run the blend" to take advantage of the new creative opportunities afforded by the newly combined elements. Consider the variant mentioned above where trucks and monsters remain separate sprites. How should they interact? We expect our initial implementation will use quite basic mechanisms, e.g. randomly selecting an event (or no event) for the interaction of the two sprites. A more radical move would be to elaborate new mechanics. For instance, monsters could commandeer and drive trucks. To give Frolda a chance to survive in this new *Mad Max* universe, it may be important to give her the opportunity to collect a bazooka that can launch missiles at the trucks. How this kind of elborative process can be realised computationally could be a direction for future research.

The player's imagination does a significant amount of work to make sense of the blend — perhaps especially in a game with limited graphics. Knowledge of the original games may help the player envision the new blended scenario. Thus, if we recognise the two source games, *Frolda* may be envisioned as an anthropomorphic frog equipped with a sword. We have only considered structural blending, but a broader view could include blending of audiovisual elements to achieve these kind of effects.

Brandt and Brandt offer a critique of conceptual blending that can help in thinking about what makes a blended game playable (Brandt and Brandt 2005). They argue that a purely *conceptual* approach to blending is not as cognitively useful as an approach that considers blends in their communicative context. In the case of games, there is both a narrative and an interactive component to the communication. This is consistent with the view from PCG that intrinsic criteria are insufficient for automated game design, and that some form of playtesting is required (Nelson et al. 2015).

## Conclusions

We have shown that it is — in principle — possible to provide a computational approach to blending games specified in VGDL, although many such blends are possible. We highlighted the opportunities for emergent meaning making that are afforded to game designers using this approach. Nevertheless, it is difficult to point to anything resembling elaboration, evaluation, or meaning-making within VGDL games themselves: for instance, the observation that a given game is unduly difficult for the player would have to come from outside. Automated playtesting could provide some of the necessary feedback to guide the blending process, and will be integral to the implementation of the approach we have outlined here.

## Acknowledgments

Many thanks to Christian Guckelsberger and the anonymous reviewers for their comments on an earlier draft of this paper. Joseph Corneli was supported by the European Commision via the COINVENT project (FP7 FET-Open grant 611553).

# Patterns of Peeragogy

Joseph Corneli, Department of Computing, Goldsmiths College, University of London
Charles Jeffrey Danoff, Mr Danoff's Teaching Laboratory
Charlotte Pierce, Pierce Press and Independent Publishers of New England
Paola Ricaurte, Department of Cultural Studies, Tecnológico de Monterrey
Lisa Snow Macdonald, independent researcher and consultant, Los Angeles

We describe nine design patterns that we have developed in our work on the Peeragogy project, in which we aim to help design the future of learning, inside and outside of institutions. We use these patterns to build an "emergent roadmap" for the project. The primary audience we envision for the paper are teams of people who aspire to collaboratively manage their own free/open/libre learning and development projects.

Categories and Subject Descriptors: K.3.1 [**Computers and Education**]: Computer Uses in Education—*Collaborative learning*; K.4.3 [**Computers and Society**]: Organizational Impacts—*Computer-supported collaborative work*

General Terms: Human Factors

Additional Key Words and Phrases: peer learning, peer production, design patterns

**ACM Reference Format:**

Corneli, J., Danoff, C.J., Pierce, C., Ricaurte, P., and Snow Macdonald, L. 2015. Patterns of Peeragogy. HILLSIDE Proc. of Conf. on Pattern Lang. of Prog. 22 (October 2015), 23 pages.

## INTRODUCTION

This paper outlines an approach to the organization of learning that draws on the principles of free/libre/open source software (FLOSS), free culture, and peer production. Mako Hill suggests that one recipe for success in peer production is to take a familiar idea – for example, an encyclopedia – and then make it easy for people to participate in building it [Hill 2013, Chapter 1]. We will take hold of "learning in institutions" as a map (Figure 1), although it does not fully conform to our chosen tacitly-familiar territory of *peeragogy*. To be clear, peeragogy is for *any group of people who want to learn anything*.[1]

Fig. 1: A university campus. Inset captions describe the buildings: "*Ladies Hall*, *Dormitories*, *University Hall*, *Library and Assembly Hall*, *Science Hall*, *President's Residence*, *University Farm*, *Observatory*." This image serves as a key to the figures that illustrate our patterns.

Although we are thinking about learning and adaptation that may take place far outside of formal institutions, the historical conception of a university helps give shape to our inquiry. The model university is not separate from the life of the state or its citizenry, but aims to "assume leadership in the application of knowledge for the direct improvement of the life of the people in every sphere" [Curti et al. 1949, p. 88]. Research that *adds to the store of knowledge* is another of its fundamental obligations [Curti et al. 1949, p. 550]. While the university provides a familiar model for collaborative knowledge work, it is not the only model available. Considering the role of online collaboration in building reference resources, Q&A sites, and free/libre/open source software, we may well ask: What would an accredited free/libre/open university look like? How would it compare or contrast with the typical or stereotypical image in Figure 1? Would it have similar structural features, like a Dormitory, Library, Science Hall and so on? Would participants take on familiar roles [Corneli and Mikroyannidis 2011]? How would it compare with historical efforts like the Tuskegee Institute that involved students directly in the production of physical infrastructure [Washington 1901; Corneli et al. 2014]?

We use the word *peeragogy* to talk about peer-led multi-way collaboration in relatively non-hierarchical settings. Examples are found in education, but also in business, government, volunteer, and NGO settings. Peeragogy involves both problem solving and problem definition, and results in learning. It can be preferable to focus on finding solutions, since people may know the "problems" all too well [Ariyaratne 1977]. Participants in a peeragogical endeavor collaboratively build emergent structures that are responsive to their changing context, and that, in turn, change that context. In the Peeragogy project, we are developing the theory and practice of peeragogy.

*Design patterns* offer a methodological framework that we have used to clarify our focus and organize our work. A design pattern expresses a commonly-occurring problem, a solution to that problem, and rationale for choosing this solution [Meszaros and Doble 1998]. This skeleton is typically fleshed out with a *pattern template* that includes additional supporting material; individual patterns are connected with each other in a *pattern language*. What we present here is rather different from previous pattern languages that touch on similar topics – like *Liberating Voices* [Schuler 2008], *Pedagogical Patterns* [Bergin et al. 2012], and *Learning Patterns* [Iba and Iba Laboratory 2014]. At the level of the pattern template, our innovation is simply to add a "What's next" annotation, which anticipates the way the pattern will continue to "resolve".

This addition mirrors the central considerations of our approach, which is all about human interaction, and the challenges, fluidity and unpredictability that come with it. Something that works for one person may not work for another or may not even work for the same person in a slightly different situation. We need to be ready to clarify and adjust what we do as we go. Even so, it is hard to argue with a sensible-sounding formula like "If W applies, do X to get Y." In our view, other pattern languages often achieve this sort of common sense rationality, and then stop. Failure in the prescriptive model only begins when people try to define things more carefully and make context-specific changes – when they actually try to put ideas into practice. The problem lies in the inevitable distance between *do as I say*, *do as I do*, and *do with me* [Deleuze 2004, p. 26].

If people are involved, things get messy. They may think that they are on the same page, only to find out that their understandings are wildly different. For example, everyone may agree that the group needs to go "that way." But how far? How fast? It is rare for a project to be able to set or even define all of the parameters accurately and concisely at the beginning. And yet design becomes a "living language" [Alexander et al. 1977, p. xvii] just insofar as it is linked to action. Many things have changed since Alexander suggested that "you will get the most 'power' over the language, and make it your own most effectively, if you write the changes in, at the appropriate places in the book" [Alexander et al. 1977, p. xl]. We see more clearly what it means to inscribe the changing form of design not just in the margins of a book, or even a shared wiki, but in the lifeworld itself. Other recent authors on patterns share similar views [Reiners et al. 2012; Schümmer et al. 2014; PLAST Collective 2015].

Learning and collaboration are of interest to both organizational studies and computer science, where researchers are increasingly making use of social approaches to software design and development, as well as agent-based models of computation [Minsky 1967; Corneli et al. 2015]. The design pattern community in particular is very familiar with practices that we think of as peeragogical, including shepherding, writers workshops, and

design patterns themselves [Harrison 1999; Coplien and Woolf 1997; Meszaros and Doble 1998]. We hope to help design pattern authors and researchers expand on these strengths. The primary audience we envision for the paper are teams of people who aspire to collaboratively manage their own free/open/libre learning and development projects.

Plan of the work

Table I shows the pattern template that we use throughout the paper. Along with the traditional design patterns components [Meszaros and Doble 1998], each of our patterns is fleshed out with two illustrative examples. The first looks at how the pattern applies in current Wikimedia projects. We selected Wikimedia as a source of examples because the project is familiar, a demonstrated success, and readily accessible. The second example shows how the pattern could be applied in the design of a free/open/libre university. Each pattern concludes with a boxed annotation that describes "*What's Next in the Peeragogy Project*". Following the convention of the design pattern literature, we write the names of patterns in small-caps. Section 1 defines the concept of PEERAGOGY more explicitly as a design pattern. Sections 2–9 present the other patterns in our pattern language. This is followed by an emergent roadmap for the Peeragogy project and a review of the broader contributions of this work. Figure 2 illustrates the interconnections between the patterns, and Table II summarizes their "nuts and bolts".

| |
|---|
| *Motivation* for using this pattern. |
| *Context* of application. |
| *Forces* that operate within the context of application, each with a mnemonic glyph. |
| *Problem* the pattern addresses. |
| *Solution* to the problem. |
| *Rationale* for this solution. |
| *Resolution* of the forces, named in bold. |
| *Example 1*: How the pattern manifests in current Wikimedia projects. |
| *Example 2*: How the pattern could inform the design of a future university. |
| *What's Next in the Peeragogy Project*: How the pattern relates to our collective intention in the Peeragogy project |

Table I. : Pattern template.

A short motivating example

When one of us was a NEWCOMER to the Peeragogy project, she hit a wall in understanding the "patterns" section in the *Peeragogy Handbook* v1. A more seasoned peer invited her to a series of separate discussions with their own HEARTBEAT to flesh out the patterns and make them more accessible. At that time the list of patterns was simply a list of paragraphs describing recurrent trends. During those sessions, the impact and meaning of patterns captured her imagination. She went on to become the champion for the pattern language and its application in the Peeragogy project. During a "hive editing" session, she proposed the template we initially used to give structure to the patterns. She helped further revise the pattern language for the *Peeragogy Handbook* v3, and attended PLoP 2015. While a new domain can easily be overwhelming, this newcomer found A SPECIFIC PROJECT to start with, and scaffolded her knowledge and contributions from that foundation.

| **Pattern** | **How can we. . .** | **Here's how:** |
|---|---|---|
| PEERAGOGY | . . . find solutions together? | *Figure out what the real problems are.* |
| ROADMAP | . . . get everyone on the same page? | *Build a plan that we keep updating.* |
| REDUCE, REUSE, RECYCLE | . . . avoid undue isolation? | *Use what's there and share what we make.* |
| CARRYING CAPACITY | . . . avoid becoming overwhelmed? | *Clearly express when we're frustrated.* |
| A SPECIFIC PROJECT | . . . avoid becoming perplexed? | *Focus on concrete, doable tasks.* |
| HEARTBEAT | . . . make the project "real" for participants? | *Keep up a regular, sustaining rhythm.* |
| WRAPPER | . . . stay in touch? | *Circulate any adjustments to the plan.* |
| NEWCOMER | . . . make the project accessible to new people? | *Let's learn together with newcomers.* |
| SCRAPBOOK | . . . maintain focus as time goes by? | *Keep coming back to the priorities.* |

Table II. : An overview of the problems and solutions in our pattern language.

## *Connections between the patterns of peeragogy*

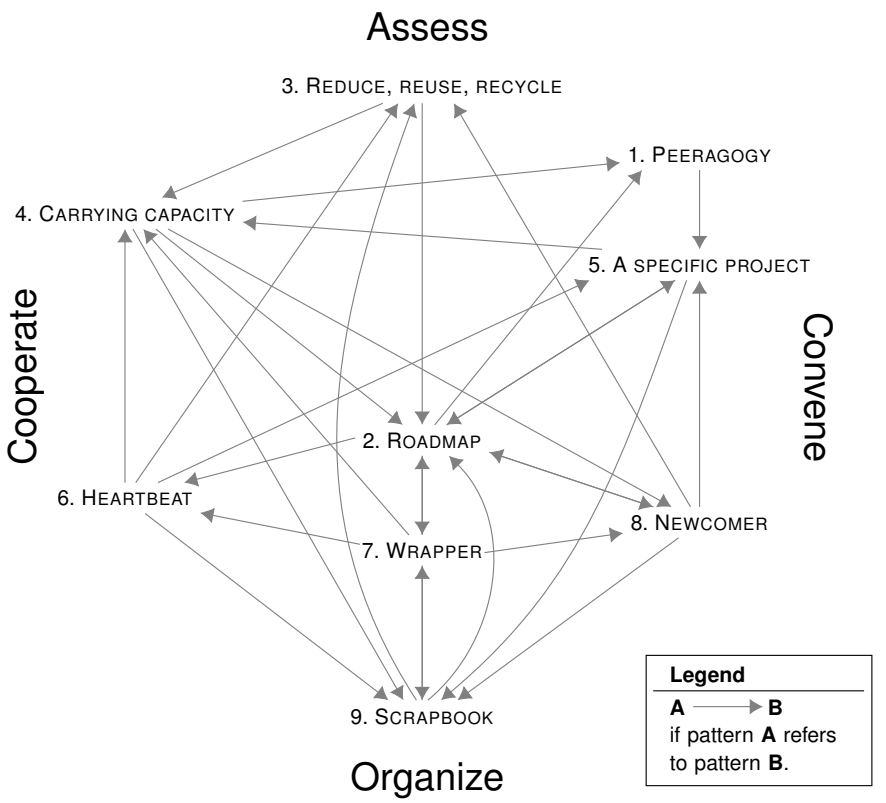

Fig. 2: Peeragogy patterns are highly interconnected. This figure shows how they fit together with and within a wider context. Specifically, the labels at the four edges of the figure correspond to the most closely related sections of the *Peeragogy Handbook*.

## PATTERN CATALOG

### 1. PEERAGOGY

*Motivation.* This pattern is relevant to anyone who wants to do active learning together with others in a relatively non-hierarchical setting.

*Context.* Collaborative projects like Wikipedia, StackExchange, and FLOSS represent an implicit challenge to the old "industrial" organization of work. This new way of working appears to promise something more resilient, more exciting, and more humane. The rhetoric has been questioned [Shaw and Hill 2014; Kreiss et al. 2011]. In and across these "free", "open", post-modern organizations, individual participants are learning [Schmidt 2009] – and that they collectively change the methods and infrastructure as they go. Because everyone in these projects primarily learns by putting in effort on a shared work-in-progress, participants are more in touch with an *equality of intelligence* than an *inequality of knowledge* [Rancière 1991, pp. 38, 119]. At the same time, they invoke a form of friendly competition, in which *the best craftmanship wins* [Raymond 2001, p. 89].

*Forces.* **Threshold**: inclusiveness and specificity are in tension.
**Trust**: is only built through sharing and reciprocity.

*Problem.* Even a highly successful project like Wikipedia is a work in progress that can be improved to better *empower and engage people around the world, to develop* richer and more useful *educational content, and to disseminate it* more *effectively* – and deploy it more creatively.[2] How to go about this is a difficult question, and we don't know the answers in advance. There are rigorous challenges facing smaller projects as well, and fewer resources to draw on. Many successful free software projects are not particularly collaborative – and the largest projects are edited only by a small minority of users [Hill 2011; Swartz 2006]. Can we work smarter together?

*Solution.* The act of asking "can we work smarter together?" puts learning front and center. Peeragogy takes that "center" and distributes it across a pool of heterogeneous relationships. Indeed, peeragogy can be understood as an up-to-date revision of Alexander's NETWORK OF LEARNING [Alexander et al. 1977, p. 99]. It *decentralizes the process of learning and enriches it through contact with many places and people* in interconnected networks that may reach all over the world. Importantly, while people involved in a peeragogical process may be collaborating on A SPECIFIC PROJECT, they don't have to be direct collaborators outside of the learning context or co-located in time or space. Just as theories and practices of pedagogy articulate the transmission of knowledge from teachers to students, peeragogy articulates the way peers produce and use knowledge together (Figure 2).

*Rationale.* The peeragogical approach particularly addresses the problems of small projects stuck in their individual silos, and large projects becoming overwhelmed by their own complexity. It does this by going the opposite route: explicating *what by definition is tacit* and employing *a continuous design process* [Schümmer et al. 2014, pp. 9–10]. As Howard Rheingold remarks in the foreword to the *Peeragogy Handbook*: "What made this work? Polycentric leadership is one key" [Rheingold et al. 2015, p. iii]. "Peer-led" shouldn't suggest that there are no leaders: rather, it means that multiple leaders act as peers.

*Resolution.* Peeragogy helps people in different projects describe and solve real problems. If you share the problems that you're experiencing with others, there's a reasonable chance that someone may be able to help you solve them. Bringing a problem across the **threshold** of someone else's awareness helps achieve clarity. This process can guide individual action in ways that we wouldn't have seen on our own, and may lead to new forms of collective action we would never have imagined possible. People who gain experience comprehending problems together build **trust**. Making room for multiple right answers contributes further to resolving the tension between generality and specificity.

[2] `https://wikimediafoundation.org/wiki/Mission_statement`

*Example 1.* Wikipedia and its sister sites Wiktionary, Wikiversity, etc. (collectively "Wikimedia") rely on user-generated content, peer produced software, and are managed, by and large, by a pool of users who choose to get involved with governance and other "meta" duties.[3] The Wikimedia Foundation maintains the servers and acts on behalf of this "global movement". They achieve something quite impressive: Wikipedia is the 7th most popular website in the world, but the Wikimedia Foundation has under 300 employees. For comparison, the 6th (Amazon) and 8th (QQ) most popular websites are run by companies with over 200K and 28K employees, respectively.[4,5,6,7]

*Example 2.* Although one of the strengths of PEERAGOGY is to distribute the workload, this does not mean that infrastructure is irrelevant. The students and researchers of the future university will need access to an Observatory and other scientific apparatus if they are to reach *ad astra, per aspera* (Figure 3).[8]

Fig. 3: *Observatory*: Space Surveillance Telescope, New Mexico.

*What's Next in the Peeragogy Project* We intend to revise and extend the *Patterns of Peeragogy* into a framework that can describe and scaffold the learning that happens inside and outside of institutions.

## 2. ROADMAP

*Motivation.* This pattern shows how your group can define the scope of their project and make a realistic plan to address it. This pattern provides the backbone of our pattern language. It can be used to find a shared goal.

*Context.* PEERAGOGY has both distributed and centralized aspects. The discussants or contributors who collaborate on a project have different points of view and heterogeneous priorities, but they come together in conversations and joint activities.

*Forces.*
- **Variety**: people have different goals and interests in mind.
- **Clarity**: some goals may be quite specific, and some rather vague.
- **Coherence**: only some of these goals will be well-aligned.

*Problem.* In order to collaborate, people need a way to share current, though incomplete, understanding of the space they are working in, and to nurture relationships with one another and the other elements of this space. At the outset, there may not even be a coherent vision for a project – but a only loose collection of motivations and sentiments. Once the project is up and running, people are likely to pull in different directions.

*Solution.* Building a guide to the goals, activities, experiments and working methods can help NEWCOMERS and old-timers alike understand their relationship with the project. It may combine features of a manifesto, a syllabus, and an issue tracker. It may be a design pattern or a pattern language [Kohls 2010]. The distinguishing qualities of a project ROADMAP are that it should be adaptive to circumstances, and that it should ultimately get us from *here* to *there*. By this same token, any given version of the roadmap is seen as fallible. In lieu of widespread participation, the project's WRAPPER should attempt to synthesize an accurate roadmap that is informed by participants' behavior, and should help moderate in case of conflict. Nevertheless, full consensus is not necessary: different goals, with different *heres* and *theres*, can be pursued separately, while maintaining communication.

[3] `https://www.wikimedia.org/`
[4] `https://en.wikipedia.org/wiki/Wikimedia_Foundation#Employees`
[5] `http://phx.corporate-ir.net/phoenix.zhtml?c=97664&p=irol-newsArticle&ID=2100418`
[6] `https://www.google.com/finance?cid=695431`
[7] `http://www.alexa.com/topsites`
[8] Latin: "With difficulty, to the stars."

*Rationale.* The group evolves from a less-sophisticated to a more-sophisticated manner of operating by using the roadmap. Using the roadmap builds a collective awareness of how things are working in practice. In the Peeragogy project our initial roadmap was a "crowdsourced" outline of the first edition of the *Peeragogy Handbook*. Later, it took the form of a schedule of meetings following a regular HEARTBEAT, supplemented by a list of upcoming deadlines. Most recently, our roadmap is expressed in the emergent objectives collected at the end of current paper. We have seen that a list of nice-to-have features created in a top-down fashion is comparatively unlikely to go anywhere! A backlog of tasks and a realistic plan for accomplishing them are vastly different things. An adaptive roadmap is an antidote to TUNNEL VISION [Dikel et al. 2001, pp. 121–124].

*Resolution.* An emergent roadmap is rooted in real problems and justifiable solutions-in-progress in all their **variety** and communicates both resolution and follow-through. The process of meshing varied issues with one another requires thought and discussion, and this encourages **clarity**. The test of **coherence** is that contributed goals and ideas should be actionable. The ultimate quality-control test is if it worked, i.e., did it come to pass that the task(s) the roadmap was created to achieve ended up being achieved? If all of the issues that the roadmap outlines are not resolved, the roadmap itself should be revised. Without a roadmap, we would never know.

*Example 1.* The *Help* link present on every Wikipedia page could be seen as a localized ROADMAP for individual user engagement: it tells users what they can do with the site, and gives instructions on how to do it.[9] For someone who knows what they're doing, there are around 30 pages listing articles with various kinds of problems, for example articles tagged with style issues, or "orphaned" articles (i.e., articles with no links from other pages in the encyclopedia).[10,11,12] In 2010-2011, Wikimedia developed a strategic plan drawing on community input [Kim et al. 2011]. In 2015, a two-week Community Consultation was carried out; synthesis resulted in "a direction that will guide the decisions for the organization."[13,14] Community-organized WikiProjects often invite and guide involvement on A SPECIFIC PROJECT.

Fig. 4: *President's Residence*, University of Alabama.

*Example 2.* In a future university run in a peer produced manner, a fancy President's Residence presumably wouldn't be needed (Figure 4). Leadership would be carried out in a more collaborative and distributed fashion. However, depending on just how distributed things are, it may turn out to be useful for project facilitators to gather at a University Hall. Whereas there is strength in numbers, there is leverage in organization. This is what the ROADMAP provides.

*What's Next in the Peeragogy Project* If it becomes clear that something needs to change about the project, that is a clue that we might need to revise our patterns or record a new one. We can use the names of the patterns to tag our upcoming tasks.

## 3. REDUCE, REUSE, RECYCLE

*Motivation.* This pattern can guide project participants in identifying and managing available resources.

[9] https://en.wikipedia.org/wiki/Help:Contents
[10] https://en.wikipedia.org/wiki/Category:Wikipedia_article_cleanup
[11] https://en.wikipedia.org/wiki/Category:Wikipedia_articles_with_style_issues
[12] https://en.wikipedia.org/wiki/Category:All_orphaned_articles
[13] https://blog.wikimedia.org/2015/02/23/strategy-consultation/
[14] https://blog.wikimedia.org/2015/08/27/strategy-potential-mobile-multimedia-translation/

*Context.* In a peer production context, you are simultaneously "making stuff" and building on the work of others.

*Forces.* **Derivative**: you don't have to do everything yourself!
**Sensemaking**: resources are useful only when you can make sense of them.
**Sharing**: your understanding gains robustness when you share with others.

*Problem.* Many projects die because the cost of REINVENTING THE WHEEL [c2] is too high. However, this is just one possible symptom of overfocus on a few priorities. Concerns may also arise if the project's output is not actually used by anyone.

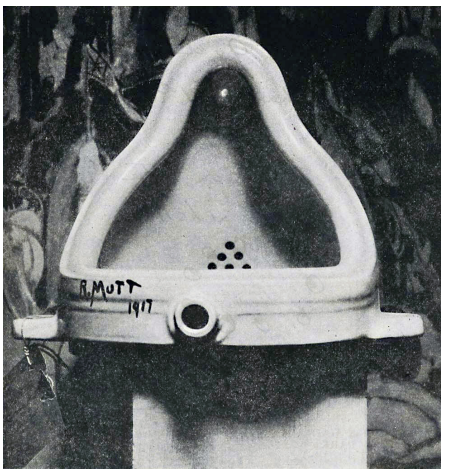

Fig. 5: A paradigmatic example of found-art. "Fountain by R. Mutt, Photograph by Alfred Stieglitz, THE EXHIBIT REFUSED BY THE INDEPENDENTS".

*Solution.* "Steal like an artist," and make it possible for other people to build on your work too (Figure 5). In the Peeragogy project, we have used off-the-shelf and hosted software suited to the task at hand (including: Drupal, Google+, Google Hangouts, Google Docs, Wordpress, pandoc, Github, ShareLaTeX). Early on we agreed to release our *Peeragogy Handbook* under the terms of the Creative Commons Public Domain Dedication (CC0), the legal instrument that grants the greatest possible leeway to downstream users.[15] This has allowed us and others to repurpose and improve its contents in other settings, including the current paper. Follow the steps indicated by the keywords in the pattern's title:

—*Reduce* the panoply of interesting interrelated ideas and methods to a functional core (e.g. writing a book).
—*Reuse* resources relevant to this aim, factoring in "things I was going to have to do anyway" from everyone involved.
—*Recycle* what you've created in new connections and relationships.

*Rationale.* Clearly we are not the first people to notice the problems with wheel-reinvention, including "missing opportunities, repeating common mistakes, and working harder than we need to."[16] As a guest in one of our hangouts, Willow Brugh, of Geeks without Bounds and the MIT Media Lab, remarked that *people often think that they need to build a community, and so fail to recognize that they are already part of a community.*[17] We converted our old pattern catalog from the *Peeragogy Handbook* into this paper, sharing it with a new community and gaining new perspectives; could we do something similar again?

*Resolution.* Reweaving old material into **derivative** designs and new material into existing frameworks, we build deeper understanding, and carry out collective **sensemaking**. The project's ROADMAP develops by making sense of existing resources – including our worries and concerns. Often we only know what these are when we attempt to **share** them. Drawing on a wide range of resources boosts our collective CARRYING CAPACITY.

*Example 1.* Contributors are encouraged to recycle existing works that are compatible with the Wikimedia-wide Creative Commons Attribution-ShareAlike (CC-By-SA) license.[18] Some sub-projects have been created purely to help repurpose other existing works in this way.[19] On the downstream side, DBPedia is an important resource

[18] https://creativecommons.org/weblog/entry/15411/
[19] https://en.wikipedia.org/wiki/Wikipedia:WikiProject_Mathematics/PlanetMath_Exchange

for the semantic web, built by collating data from Wikipedia's "infoboxes".[20] These infoboxes are themselves increasingly being populated automatically using information from WikiData.[21] Researchers have been able to develop tools that reuse Wikipedia content in other ways [Reinhold 2006; Riche et al. 2010], However, these research projects do not always result in a tool that is accessible to day-to-day users.

*Example 2.* The knowledge resources and collaboration tools currently available online are what make a low-cost, high-quality, formally-accredited future university conceivable. However, the available resources are not always as organized as they would need to be for educative purposes, so peeragogues can usefully put effort into REDUCE, REUSE, RECYCLE'ing available resources into a functioning university Library.

> *What's Next in the Peeragogy Project* Are there other educational resources and peeragogical case studies that we could fold into our work? Can we recycle material from the *Peeragogy Handbook* into a format that is easier to understand and apply?

## 4. CARRYING CAPACITY

*Motivation.* This pattern can help project participants recognize and communicate their stresses to make themselves and the project more resilient.

*Context.* One of the important maxims from the world of FLOSS is: "Given enough eyeballs, all bugs are shallow" [Raymond 2001, p. 30]. A partial converse is also true: there's only so much any one person can do, since we all have limited time and energy.

*Forces.* **Antifragility**: each person's potential can only be realized if people take on enough, but not too much. 

**Independence**: in a peeragogy context, it is often impossible to delegate work to others. 

*Problem.* How can we help prevent those people who are involved with the project from over-promising or over-committing, and subsequently crashing and burning? First, let's be clear that there are lots of ways things can go wrong. Simplistic expectations – like *assuming that others will do the work for you* [Torvalds and Vaughan-Nichols 2011] – can undermine your ability to correctly gauge your own strengths, weaknesses, and commitments. Without careful, critical engagement, you might not even notice when there's a problem. Where one person has trouble letting go, others may have trouble speaking up. Pressure builds when communication isn't going well.

*Solution.* Serious frustration is a sign that it's time to revisit the group's ROADMAP and your own individual plan. Are these realistic? If you have a "buddy" they can provide a reality check. Maybe things are not *that hard* after all – and maybe they don't need to be done *right now*. Generalizing from this: the project can promote an open dialog by creating opportunities for people to share their worries and generate an emergent plan for addressing them [Seikkula and Arnkil 2006]. Use the project SCRAPBOOK to make note of obstacles. For example, if you'd like to pass a baton, you'll need someone there who can take it. Maybe you can't find that person right away, but you can bring up the concern and get it onto the project's ROADMAP. The situation is always changing, but if we continue to create suitable checkpoints and benchmarks, then we can take steps to take care of an issue that's getting bogged down.

*Rationale.* Think of the project as an ecosystem populated by acts of participation. As we get to know more about ourselves and each other, we know what sorts of things we can expect, and we are able to work together

[20] `http://wiki.dbpedia.org/`
[21] `https://www.wikidata.org/wiki/Wikidata:Main_Page`

more sustainably [Ostrom 2010]. We moderate stress and improve collective outcomes by taking concerns seriously.

*Resolution.* Guiding and rebalancing behavior in a social context can begin with speaking up about a concern. When we acknowledge concerns, we must take into account our own boundedness. We have find an opportunity to make ourselves helpful, without impinging on others' **independence**. This doesn't mean allowing all possible stresses to run rampant: we work to stay within the realm of **antifragility**, where manageable stress *improves* the system rather than degrading it [Taleb 2012]. As we share concerns and are met with care and practical support, our actions begin to align better with expectations (often as a result of forming more realistic expectations).

*Example 1.* Wikipedia aims to emphasize a neutral point of view, but its users are not neutral.[22] Users "speak up" about topics that matter to them.[23] Coverage and participation are not neutral in another less sanguine sense. More information on Wikipedia deals with Europe than all of the locations outside of Europe [Graham et al. 2014]. As we remarked in the PEERAGOGY pattern, most of the actual work is contributed by a small percentage of users. The technology limits the kinds of things that can be said [Graham et al. 2014]. The total number of active editors has been falling since 2007.[24] Some blame outmoded technology and an insider culture [Simonite 2013], or a stringent editorial approach that emerged in response to the site's popularity [Halfaker et al. 2013]. Others highlight the rise of successful competition, often inspired by wiki models, but driven by "corporate logic" [Kreiss et al. 2011; Morell 2011]. Some proposed solutions focus on various indicators of "community health".[25]

*Example 2.* Progressive thinkers have for some time subscribed to the view that "there shall be no women in case there be not men, nor men in case there be not women" [Rabelais 1894, Chapter 1.LII]. A separate Ladies Hall seems entirely archaic (Figure 6). However, in light of the extreme gender imbalance in free software, and still striking imbalance at Wikipedia [Ghosh et al. 2002; Reagle 2012], it will be important to do whatever it takes to make women and girls welcome, not least because this is a significant factor in boosting our CARRYING CAPACITY.

Fig. 6: *Ladies Hall*: Queens College, North Carolina.

*What's Next in the Peeragogy Project* Making it easy and fruitful for others to get involved is one of the best ways to redistribute the load. This often requires knowledge transfer and skill development among those involved; see NEWCOMER.

## 5. A SPECIFIC PROJECT

*Motivation.* This pattern can help project participants get started, get focused, and make concrete change. It is especially useful for someone who is currently feeling stuck.

*Context.* We often find ourselves confronted with what seems to be a difficult, complex, or even insurmountable problem. It won't go away, but a workable solution doesn't present itself, either. If there is a candidate solution, it's also clear there are not enough resources for it to be feasible.

[22] https://en.wikipedia.org/wiki/Wikipedia:Neutral_point_of_view
[23] https://en.wikipedia.org/wiki/Wikipedia:Activist
[24] https://strategy.wikimedia.org/wiki/Editor_Trends_Study/Results
[25] https://lists.wikimedia.org/pipermail/wiki-research-l/2016-January/004959.html

*Forces.* **Difficulty**: bringing about meaningful change is often hard work.
**Inertia**: when things are hard we may feel stuck, wring our hands, or preach to the choir.

*Problem.* One is often blinded by one's prejudices and preferences. Some may put considerable energy into pondering, discussing, exploring and feeling stuck. Some may want more concrete progress, and notice the time passing by. In a group setting, when the forward-movers ultimately try to act, those who are more wrapped up in the experience of pondering and exploring may rebel, if they feel that they are being left behind. Inaction may seem like the only safe choice, but it has risks too. And, once moving, things can easily get bogged down again.

*Solution.* One way to make progress when you're stuck is to ask a specific question to someone who may be able to help you get unstuck. Formulating a question helps your thinking become more concrete. Sometimes you'll see that a solution was within your grasp all along. Often, one question won't be enough, but you can repeat the process. In this way, you can reduce a large, complex, or ephemeral concern into a collection of smaller, specific, manageable tasks with clear next steps and success criteria. Use a SCRAPBOOK to make note of all the small things, and weave them into your project ROADMAP. This will show how the small pieces relate to the bigger picture. If you have a fairly specific idea about what you want to do, but you're finding it difficult to get it done, don't just ask for advice: recruit material help (cf. CARRYING CAPACITY). One example of a specific project from the Peeragogy project is our work on this paper, which had a specific target audience, a set of associated deadlines, and allowed us to get help from pattern experts.

*Rationale.* We've seen time and again that having a specific project is a recipe for getting concrete, and that getting concrete is necessary for bringing about change. Asking for help (which is what happens when you vocalize a question) is one of the best ways to gain coherence. Making yourself understood can go a long way toward resolving deeper difficulties.

*Resolution.* Where you run into **difficulty**, getting specific paves the way for incremental forward progress and helps to overcome **inertia**. The struggle between consensus and action is resolved in a tangible project that combines action with dialog. Learning something new is a strong sign that things are working. In the Peeragogy project, we have completed many projects during our weekly hangouts, for example "hive editing" an abstract for submission to a conference.

*Example 1.* At first glance, the Wikimedia Foundation's mission may seem like a good idea, but hard to do anything about.[26] In practice, many Wikipedians contribute to the mission by working on A SPECIFIC PROJECT. Within Wikipedia, these are known as "WikiProjects."[27,28] Guidance is available on how to start new WikiProjects.[29] The Wikimedia Foundation also runs other public projects, including the Wikipedia Education Program and the GLAM Wiki (for Galleries, Libraries, Archives, and Museums).[30,31] The latter maintains a *list of case studies that describes specific projects undertaken by cultural organizations and Wikimedia*.[32]

Fig. 7: *Dormitory*, Ruin Academy, Taipei, Taiwan.

*Example 2.* Collegial and convivial peer support via remote collaboration or short-term meet-ups may fill some of the requirements

[26] https://wikimediafoundation.org/wiki/Mission_statement
[27] https://en.wikipedia.org/wiki/Wikipedia:WikiProject_Council/Directory
[28] https://en.wikipedia.org/wiki/Wikipedia:WikiProject_Council/Guide
[29] https://en.wikipedia.org/wiki/Wikipedia:WikiProject_Council/Guide/WikiProject
[30] https://outreach.wikimedia.org/wiki/Education/Wikipedia_Education_Collaborative/Tasks
[31] https://outreach.wikimedia.org/wiki/GLAM
[32] https://outreach.wikimedia.org/wiki/GLAM/Case_studies

of “student life”. Peeragogy can also happen in neighborhoods, and among persons sharing long-term co-habitation. While a traditional Dormitory may not be necessary, a shared rented or cooperatively-owned living/working environment could be an asset for peeragogues working together on A SPECIFIC PROJECT (Figure 7).

> *What’s Next in the Peeragogy Project* Let’s use our pattern catalog to build specific, tangible “what’s next” steps, add them to our ROADMAP, and carry them out with concrete actions. Let’s be sure we know who’s responsible for what, and employ a “buddy system” to help get things done.

## 6. HEARTBEAT

*Motivation.* This pattern can help project participants stay in touch, and stay motivated.

*Context.* A number of people have a shared interest, and have connected with each other about it. However, they are not going to spend 24 hours a day, 7 days a week working together, either because they are busy with other things, or because working separately on some tasks is vastly more efficient.

*Forces.* **Differentiation**: the time we spend together isn’t all equally meaningful. 
**Entropy**: something needs to hold the project together, or it will fall apart. 

*Problem.* How will the effort be sustained and coordinated sufficiently? How do we know this an active collaboration, and not just a bunch of people milling about? Is there a *there, there?*

*Solution.* People seem to naturally gravitate to something with a pulse. *Once a day* (stand-ups), *once a week* (meetings), or *once a year* (conferences, festivals) are common variants. When the project is populated by more than just a few people, it’s likely that there will be several HEARTBEATS, building a sophisticated polyrhythm. A well-running project will feel “like an improvisational jazz ensemble” [Dikel et al. 2001]. Much as the band director may gesture to specific players to invite them to solo or sync up, a project facilitator may craft individual emails to ask someone to lead an activity or invite them to re-engage. Two common rhythm components are weekly synchronous meetings with an open agenda, combined with *ad hoc* meetings for focused work on A SPECIFIC PROJECT. The precise details will depend on the degree of integration required by the group.

*Rationale.* The project’s heartbeat is what sustains it. Just as *people matter more than code* [Torvalds and Vaughan-Nichols 2011], so does the life of the working group matter more than mechanics of the work structure. Indeed, there is an quick way to do a reality check and find the project’s strongest pulse: the activities that sustain a healthy project should sustain us, too (cf. CARRYING CAPACITY).

*Resolution.* Noticing when a new HEARTBEAT is beginning to emerge is a way to be aware of the shifting priorities in the group, and contributes to further **differentiation**. This may ultimately be a good source of new patterns. On the other hand, if a specific activity is no longer sustaining the project, stop doing it, much as you would move an out-of-date pattern to the SCRAPBOOK in order to make room for other concerns. The power of the HEARTBEAT is that the project can be as focused and intensive as it needs to be, working against **entropy** in the ways that start to be required as time goes by.

*Example 1.* The yearly in-person gathering, Wikimania, is the most visible example of a HEARTBEAT for the Wikimedia movement.[33] Local chapters and projects may run additional in-person get-togethers.[34] Also of note is the twice-yearly call for proposals for individual engagement grants.[35] There are other shorter cycles. Each day

[33] https://meta.wikimedia.org/wiki/Wikimania
[34] http://wikiconferenceusa.org/
[35] https://meta.wikimedia.org/wiki/Grants:IEG

Fig. 8: *University Farm*: al-Biruni University, Kapisa province, Afghanistan.

a highly-vetted Featured Article appears on the front page of Wikipedia, and is circulated to a special-purpose mailing list.[36,37,38] The discussion of articles for deletion lasts at least seven days.[39]

*Example 2.* Although it may sound quaint, some variant of the University Farm could help to physically sustain peeragogues, while putting the project's HEARTBEAT in tune with that of the seasons (Figure 8). In the current distributed mode, we tend our window boxes and allotment gardens. New developments should unfold in a *logical order growing out of the needs of the community* [Washington 1901, Chapter IX].

> *What's Next in the Peeragogy Project* Identifying and fostering new HEARTBEATS and new working groups can help make the community more robust. This is the time dimension of spin-off projects described in REDUCE, REUSE, RECYCLE.

## 7. WRAPPER

*Motivation.* This pattern suggests to find at least one person to fill an important role managing the project's public interface, and keeping participants up to date about activities.

*Context.* You are part of an active, long-running, and possibly quite complex project with more than a handful of participants. How do you manage?

*Forces.* **Interface**: the project shows people how they can use it.
**Familiarity**: the leader/follower dichotomy is easy to understand.
**Equity**: peeragogy aims for fairness.

*Problem.* In an active project, it can be effectively impossible to stay up to date with all of the details. Not everyone will be able to attend every meeting (see HEARTBEAT) or read every email. Project participants can easily get lost and drift away. The experience can be much more difficult for NEWCOMERS: joining an existing project

[36] https://en.wikipedia.org/wiki/Wikipedia:Today%27s_featured_article
[37] https://en.wikipedia.org/wiki/Wikipedia:Featured_article_candidates
[38] https://lists.wikimedia.org/mailman/listinfo/daily-article-l
[39] https://en.wikipedia.org/wiki/Wikipedia:Articles_for_deletion

can feel like trying to climb aboard a rapidly moving vehicle. Information overload is not the only concern: there is also a problem with missing information. If key skills are not shared, they can quickly become bottlenecks (see CARRYING CAPACITY).

*Solution.* Someone involved with the project should regularly create a wrap-up summary, distinct from other project communications, that makes current activities comprehensible to people who may not have been following all of the details. In addition, project members should keep other informative resources like the landing page, ROADMAP, and documentation up to date. Check empirically to see if they really show interested parties how they can get involved. Building on the idea of a "project dashboard" in Figure 9, we can guide potential contributors to live help; we can then see what questions they ask.[40] The WRAPPER is both a role, and, sometimes, an artifact. Our *Handbook*'s cover literally wraps up its contents; the collaboratively written chat notes from our weekly Hangouts give a collaboratively-written overview of what was discussed in the meeting. Meetings themselves can be structured to give people a chance to sum up what they've accomplished during the week, as well as any problems they are running into. Between meetings, each participant is advised to maintain some sort of "learning log" in the form of a personal SCRAPBOOK, so that outstanding concerns are surfaced and available to discuss.

*Rationale.* According to the theory proposed by Yochai Benkler, for free/open "commons-based" projects to work, it is important for participants to be able to contribute small pieces, and for the project to have a way to stitch those pieces together [Benkler 2002]. The WRAPPER helps perform this integrative stitching function. If you value participation, you may have to do some serious work to facilitate access to process.

*Resolution.* Well-maintained records chronicle the project's history; up-to-date documentation makes the project more robust; a coherent look-and-feel offers an accessible **interface** to the outside world. Regularly circulated summaries can help to engage or re-engage members of a project, and can give an emotional boost to peeragogues who see their contributions and concerns mentioned, giving less engaged participants the **familiar** experience of "following" someone else's updates. People will judge from experience whether the project strives for **equity** or strives to maintain hidden power differentials.

*Example 1.* There are many data streams around the Wikimedia project. They comprise an elaborate WRAPPER function for the project, with components that range from Today's Featured Article, which appears on the front page of Wikipedia, to formal annual reports from the nonprofit.[41,42]

*Example 2.* In-person meetings are just as relevant for contemporary humans as they were a century ago, even though we have learned more about how to assemble on the fly [Rheingold 2007]. Getting together for conventions, dance parties, and commencement ceremonies could comprise an important part of the future university's WRAPPER function, even if these events do not always take place in one specific Assembly Hall.

> *What's Next in the Peeragogy Project* Let's make sure we have protocols in place that enable us to share progress, and to revise our "next steps" if people are getting stuck. Let's improve the interaction design for peeragogy.org so that it's clear how people can get involved.

## 8. NEWCOMER

*Motivation.* This pattern can help project participants be aware of the issues faced by newcomers, and cultivate a "beginner's mind" themselves.

[40] `https://gitter.im/orgs/Peeragogy/rooms`
[41] `https://en.wikipedia.org/wiki/Wikipedia:Today%27s_featured_article`
[42] `https://wikimediafoundation.org/wiki/Annual_Report`

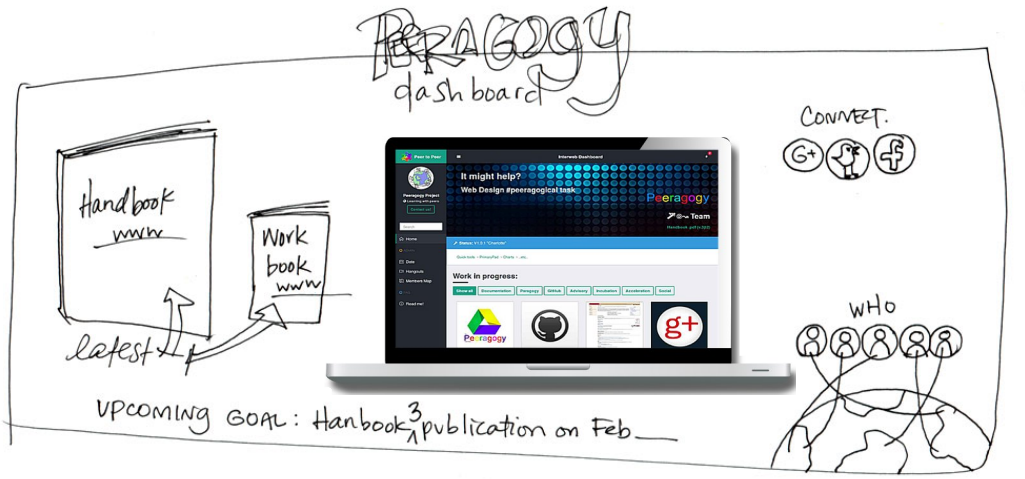

Fig. 9: Design for a Peeragogy project dashboard (sketch by Amanda Lyons, prototype by Fabrizio Terzi; images used with permission).

*Context.* When there's learning happening, it's because there is someone who is new to a topic, or to something about the topic.

*Forces.* **Individuation**: each person learning optimally is what's best for the community.
**Mutuality**: our individuality does not isolate us from one another, but draws us together.

*Problem.* Newcomers can feel overwhelmed by the amount of things to learn. They often don't know where to start. They may have a bunch of ideas that the old-timers have never considered – or they may think they have new ideas, which are actually a different take on an old idea; see REDUCE, REUSE, RECYCLE. People who are new to the project can tell you what makes their participation difficult. Since you're learning as you go as well, you can ask yourself the same question: what aspects of this encounter are difficult for me?

*Solution.* Instead of thinking of newcomers as "them", and trying to provide solutions, we focus on newcomers as "us" – which makes the search for solutions that much more urgent. We permit ourselves to ask naive questions. We entertain vague ideas. We add concreteness by trying A SPECIFIC PROJECT. We may then genuinely turn to others for help. We aim to foster a culture in which the focus for everyone is on addressing our own learning challenges rather than on "providing" solutions for others [Boud and Lee 2005]. When you begin a new project, try to systematically take notes and gather data to analyze and reflect upon later; leave artifacts for other future newcomers to use and build upon in their own research. In practice this may be a lot to ask for someone just joining a group, but over time we may have many ways to structure our collective engagement so that it leads to research cycles based on the "action research" steps *reflect*, *plan*, *act*, and *observe*. Note that there is a parallel with the four facets *assess*, *convene*, *organize*, *cooperate* from Figure 2. The history of the action research approach, with particular emphasis on educational applications, is surveyed in [McNiff 2013, Chapter 3]. One method for doing the reflection/assessment step is presented in the SCRAPBOOK pattern. Be flexible: networked attention (even more so than rigid cycles [Engeström 1999]) leads to new ways of knowing and expanded access to knowledge-production [Simondon 2012; Wagner 2008].

*Rationale.* A newcomer's confusion about how best to get involved or what the point of all this actually is may be due to a lack of structure in the project ROADMAP. Sharing vulnerability and confusion gives us a chance to learn.

*Resolution.* An awareness of the difficulties that newcomers face can help us be more compassionate to ourselves and others. We strengthen the community by supporting all participants' **individuation**. We have a better chance of making the project useful for others if we're clear about how it is useful to *us*. By welcoming newcomers, we enhance the sense of **mutuality** with people who have never encountered the project before, and learn together with them. The facts start to become useful when we understand how people perceive them [Freire 1982].

*Example 1.* Wikipedia NEWCOMERS can make use of resources that include a "Teahouse" where questions are welcomed, a platform extension that changes the user interface for new editors, and lots of documentation.[43,44,45] The efforts of exceptional newcomers may be given special recognition.[46] Newcomer "survival" is of interest to the Wikimedia Foundation.[47] However, "Nearly all editors begin with a burst of activity, then quickly tail off" [Panciera et al. 2009]. The degree to which those editors who are retained strive to maintain a "beginner's mind" is less clear. As regards learning their way around the community, there is quantitative support [Panciera et al. 2009] for the claim that "novice users learn the rules and conventions for contributing both through observation and direct coaching from more knowledgeable others" [Bryant et al. 2005].

*Example 2.* It will often be pragmatic to connect NEWCOMERS with employment directly, so that the future university may see a closer coupling of science and industry than would be found in the old Science Hall (Figure 10). Inspiration can be drawn the London-based freelancing cooperative Founders&Coders, which is able to offer intensive training in web development at no cost to successful applicants, on the basis that some trainees will choose to join the cooperative as paying members later on.[48]

Fig. 10: *Science Hall*: Aspatria Agricultural College, Aspatria, Cumberland, UK

*What's Next in the Peeragogy Project* More detailed guides can show NEWCOMERS how they can contribute and what to expect when they do. We should have different guides for different "user stories". We can start by listing some of the things we're currently learning about.

## 9. SCRAPBOOK

*Motivation.* This pattern describes a way to make the project meaningful.

*Context.* We have been working together for a while now. We have maintained and revised our pattern catalog, and we are achieving some of the "What's Next" steps associated with some of the patterns.

*Forces.* **Attention**: due to limited energy, we need to ask: where should we set the focus?
**Interest**: new experiences catch our attention.
**Meaning**: shared history makes things meaningful.

[43] https://en.wikipedia.org/wiki/Wikipedia:Teahouse
[44] https://en.wikipedia.org/wiki/Wikipedia:GettingStarted
[45] https://en.wikipedia.org/wiki/Help:Editing
[46] https://en.wikipedia.org/wiki/Template:The_New_Editor%27s_Barnstar
[47] https://meta.wikimedia.org/wiki/Research:Newcomer_survival_models
[48] http://www.foundersandcoders.com/academy/

*Problem.* Not all of the ideas we've come up with have proved workable. Not all of the patterns we've noticed remain equally relevant. In particular, some patterns no longer lead to concrete next steps.

*Solution.* In order to maintain focus, is important to "tune" and "prune" the things we give our attention to. We can connect this understanding to any actions undertaken in the project by asking questions like these:

> (1) Review what was supposed to happen. (2) Establish what is happening/happened. (3) Determine what's right and wrong with what we are doing/have done. (4) What did we learn or change? (5) What else should we change going forward? [Rheingold et al. 2015, Chapter 28], after [US Army 1993].

Other review processes have been formalized, including the design review in architecture and the postmortem in theater and other teamwork settings [Mathers et al. 2013; Kerth 2001]. The review process may benefit from having an experienced facilitator on board [Gabriel 2002, pp. 67, 142–143]. As current priorities become clearer, we decide where to focus. Anything that isn't receiving active attention should be moved to a SCRAPBOOK. This may encompass:

—*Retired patterns* that are tabled or completed (no more next steps);

—*Proto-patterns* made of problems, issues, and concerns;

—*A back-catalog* of publications, reports, or other artifacts.

In the Peeragogy project, alongside our patterns we initially maintained a collection of antipatterns (like 'MAGICAL THINKING') but the next steps coming from these seemed particularly convoluted and abstract. So, we archived them.[49] We present a list of outstanding problems – without known solutions – right up front in the Introduction to the *Peeragogy Handbook* [Rheingold et al. 2015, Chapter 1]. Other proto-patterns include 'ONBOARDING' and 'DON'T QUIT YOUR DAY JOB', which arose in our review of this paper (see "Emergent Roadmap", below). Our back-catalog includes academic papers [Corneli et al. 2014, 2013; Corneli 2012; Corneli and Danoff 2011] and a thesis [Corneli 2014]. Everyone can maintain their own personal SCRAPBOOK as along with a communal one. Furthermore, you don't need to limit yourself to *your own* creativity: include interesting ideas from other sources (see REDUCE, REUSE, RECYCLE). In some cases a designated WRAPPER may have to do further work to elicit and organize contributions.

*Rationale.* We want to keep attention focused on the most relevant issues. If a pattern, task, or concern does not lead to concrete "next steps" at the moment, sufficient time for reflection may offer a better understanding, and it may prove useful and actionable in a different context.

*Resolution.* Judicious use of the SCRAPBOOK can help focus project participants' **attention** on current concerns, without losing grasp of items of **interest**. The currently active pattern catalog is leaner and more action-oriented as a result. If the ROADMAP shows where we're going, it is the SCRAPBOOK that shows most clearly where we've been, and collects the observations that are most **meaningful** to us.

*Example 1.* The history of the Wikimedia Foundation, and of Wikipedia, are maintained as wiki pages.[50,51] One of the entries on Wikipedia details outstanding issues, in the form of critiques.[52] There are many tools available to

[49] http://paragogy.net/Scrapbook

help facilitate the process of vetting proposed fine-grained changes to articles.[53,54] Policy concerns are typically discussed at the Village Pump, and there are mechanisms in place for settling disputes.[55,56]

*Example 2.* Just as a university campus grows and changes over time, future peeragogues will be drawn to new problems and patterns. They will trace new paths and build new emergent structures (Figure 11).

> *What's Next in the Peeragogy Project* After pruning back our pattern catalog, we want it to grow again: new patterns are needed. One strategy would be to turn the whole *Peeragogy Handbook* into design patterns.

## EMERGENT ROADMAP

Table III reprises the "What's Next" steps from all of the previous patterns, offering another view on the Peeragogy project's ROADMAP in a concrete emergent form. This table has been vetted by project participants, who suggested revisions. This led to an outline for a new pattern, 'ONBOARDING', a facilitative process that would complement NEWCOMER and WRAPPER.[57] We also tagged many of the items in our list of upcoming tasks with the names of patterns in the pattern catalog.[58] However, the techniques that we have described in these patterns reach far beyond our own project. In many cases, the ideas are ancient, or even primordial (like HEARTBEAT). The patterns can be applied with or without high technology. The Peeragogy project is one of

> "[T]ens of thousands of projects in the traditions of world improvement élan – without any central committee that would have to, or even could, tell the active what their next operations should be." [Sloterdijk 2013, p. 402]

| 1. PEERAGOGY |
| --- |
| We intend to revise and extend the *Patterns of Peeragogy* into a framework that can describe and scaffold the learning that happens inside and outside of institutions. |
| 2. ROADMAP |
| If it becomes clear that something needs to change about the project, that is a clue that we might need to revise our patterns or record a new one. We can use the names of the patterns to tag our upcoming tasks. |
| 3. REDUCE, REUSE, RECYCLE |
| Are there other educational resources and peeragogical case studies that we could fold into our work? Can we recycle material from the *Peeragogy Handbook* into a format that is easier to understand and apply? |
| 4. CARRYING CAPACITY |
| Making it easy and fruitful for others to get involved is one of the best ways to redistribute the load. This often requires knowledge transfer and skill development among those involved; see NEWCOMER. |
| 5. A SPECIFIC PROJECT |
| Let's use our pattern catalog to build specific, tangible "what's next" steps, add them to our ROADMAP, and carry them out with concrete actions. Let's be sure we know who's responsible for what, and employ a "buddy system" to help get things done. |
| 6. HEARTBEAT |
| Identifying and fostering new HEARTBEATS and new working groups can help make the community more robust. This is the time dimension of spin-off projects described in REDUCE, REUSE, RECYCLE. |
| 7. WRAPPER |
| Let's make sure we have protocols in place that enable us to share progress, and to revise our "next steps" if people are getting stuck. Let's improve the interaction design for peeragogy.org so that it's clear how people can get involved. |
| 8. NEWCOMER |
| More detailed guides can show NEWCOMERS how they can contribute and what to expect when they do. We should have different guides for different "user stories". We can start by listing some of the things we're currently learning about. |
| 9. SCRAPBOOK |
| After pruning back our pattern catalog, we want it to grow again: new patterns are needed. One strategy would be to turn the whole *Peeragogy Handbook* into design patterns. |

Table III. : What's next in the Peeragogy project

When we talk about "next steps," we aim to show what can be realistically expected from us. And yet, the emergent ROADMAP also goes beyond specific individuals in the project, who will come and go.

Despite its tendency to longevity, robustness, and widespread applicability, peeragogy does have limits. For example, the benefits to collaboration notwithstanding, "there is no substitute for really hard thinking on your own" [Atiyah 1974]. Nevertheless, even the most independent knowledge worker reads and publishes: and humans are social animals. The question is usually how best – not whether – to involve others [Coase 1937; Benkler 2002]. This relates to another prospective pattern: 'DON'T QUIT YOUR DAY JOB'. Peer learning and peer production can build amazing resources, but they don't always pay the bills. That said, we have thought a lot about how the Peeragogy project could be deployed as a project accelerator built the commons-based peer production way, and

what that might mean from a business standpoint [Corneli et al. 2014]. Possible revenue streams include book sales and membership fees – as well as good old fashioned service provision.[59] At the moment there is no final agreement, but the presence of questions about the business aspects of the project may be a "clue" pointing in the direction of another pattern.

There is a further issue that presents more of a paradox. We can't dictate the behavior of other participants, and we often can't guess ourselves what's coming up. A peeragogical ROADMAP should prepare people for the *absence* of clear step-by-step direction, the *presence* of different viewpoints and priorities, and the consequent *requirement* to be reasonably self-directed. Many features of the peeragogical approach would be irrelevant to a project that is managed in a top-down fashion, and that can rely on other coordination mechanisms (like contracts) to manage work. Peeragogy is relevant when we must define or redefine the problems together.

## CONCLUSION

This paper presents nine patterns of peeragogy and connects them to concrete next steps for the Peeragogy project. In order to demonstrate generality, we included examples that illustrate how the patterns manifest in current Wikimedia projects, and how they could inform the design of a future university rooted in the values and methods of peer production. The university metaphor need not constrain the future application of the ideas, which cut across many modes of engagement (Figure 12). Even so, a project to translate the free/libre/open university from metaphor to reality would offer an intriguing opportunity to test the generality of Hill's hypothesis on the mobilizing potential of "the combination of a familiar goal (e.g., 'simply reproduce Encyclopedia Britannica') with innovative methods (e.g., 'anybody can edit anything')" [Hill 2013, p. 13]. We close by reviewing our approach to the organization of learning, using three dimensions of analysis that have been previously applied to describe research on peer production [Benkler et al. 2015].

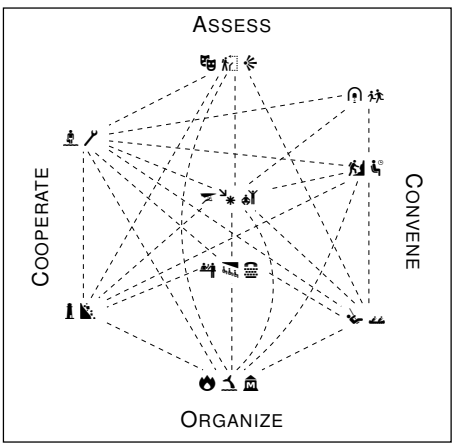

Fig. 12: Mnemonic

*Organization.* Managing work on our project with design patterns that are augmented with a "What's next" follow-through step allows us to "set and execute goals in a decentralized manner" [Benkler et al. 2015], reintegrating structure in the form of an emergent ROADMAP. Our methods apply at varied levels of scale and degrees of formality, inside or outside of institutional frameworks. If you already write patterns, you can add a "What's next" step to them and try the approach for yourself.

*Motivation.* The future of learning may be the *Chartres of programming* [Alexander 1999], but it will have plenty in common with the bazaar [Raymond 2001]. Philipp Schmidt indicates that *learning is at the core of peer production communities* [Schmidt 2009]. Our patterns help to explicate the way these communities work, but more importantly, we hope these patterns will help potentiate a global culture of collaborative learning, inside and outside of institutions.

*Quality.* "By intervening in real communities, these efforts achieve a level of external validity that lab-based experiments cannot" [Benkler et al. 2015]. The "What's next" annotation piloted here will be helpful to other design pattern authors who aim to use patterns as part of a research intervention. Peer production is not guaranteed to out-compete proprietary solutions [Benkler et al. 2015; Hill 2011]: its potential for success will depend on the way the problems are framed, and our ability to follow through.

# Implementing feedback in creative systems: A workshop approach

**Joseph Corneli[1] and Anna Jordanous[2]**
[1] Department of Computing, Goldsmiths College, University of London
[2] School of Computing, University of Kent

## Abstract

One particular challenge in AI is the computational modelling and simulation of creativity. Feedback and learning from experience are key aspects of the creative process. Here we investigate how we could implement feedback in creative systems using a social model. From the field of creative writing we borrow the concept of a Writers Workshop as a model for learning through feedback. The Writers Workshop encourages examination, discussion and debates of a piece of creative work using a prescribed format of activities. We propose a computational model of the Writers Workshop as a roadmap for incorporation of feedback in artificial creativity systems. We argue that the Writers Workshop setting describes the anatomy of the creative process. We support our claim with a case study that describes how to implement the Writers Workshop model in a computational creativity system. We present this work using patterns other people can follow to implement similar designs in their own systems. We conclude by discussing the broader relevance of this model to other aspects of AI.

## 1 Introduction

In educational applications it would be useful to have an automated tutor that can read student work and make suggestions based on diagnostics, like, is the paper wrong, and if so how? What background material should be recommended to the student for review?

In the current paper, we "flip the script" and look at what we believe to be a more fundamental problem for AI: computer programs that can themselves learn from feedback. After all, if it was easy to build great automatic tutors, they would be a part of everyday life. As potential users (thinking from both sides of the desk) we look forward to a future when that is the case.

Along with automatic tutoring, computational creativity is a challenge within artificial intelligence where feedback plays a vital part (for example Pérez y Pérez, Aguilar, & Negrete, 2010; Pease, Guhe, & Smaill, 2010). Creativity cannot happen in a 'silo' but instead is influenced and affected by feedback and interaction with others (Csikszentmihalyi, 1988; Saunders, 2012). Computational creativity researchers are starting to place more emphasis on social interaction and feedback in their systems and models (Saunders, 2012; Gervás & León, 2014; Corneli et al., 2015). Still, nearly 3 in 4 papers at the 2014 International Conference for Computational Creativity[1] failed to acknowledge the role of feedback or social communication in their computational work on creativity.

To highlight and contribute towards modelling feedback as a crucial part of creativity, we propose in this paper a model of computational feedback for creative systems based on Writers Workshops (Gabriel, 2002), a literary collaborative practice that encourages interactive feedback within the creative process. We introduce the Writers Workshop concept (Section 2) and critically reflect on how it could encourage serendipity and emergence in computational models of intelligence and creativity. These considerations lead us to propose a Writers Workshop computational model of feedback in computational creativity and AI systems (Section 2.1), the central contribution of this paper. In Section 3 we consider how the Writers Workshop model fits into previous work in various related areas. While we acknowledge that this paper is offering a roadmap for this model rather than a full implementation, we consider how the model could be practically implemented in a computational system and report our initial implementation work (Section 4). In concluding discussions, we reflect on divergent directions in which this work could potentially be useful in the future.

## 2 The Writers Workshop

Richard Gabriel (2002) describes the practise of Writers Workshops that has been put to use for over a decade within the Pattern Languages of Programming (PLoP) community. The basic style of collaboration originated much earlier with groups of literary authors who engage in peer-group critique. Some literary workshops are open as to genre, and happy to accommodate beginners, like the Minneapolis Writers Workshop[2]; others are focused on professionals working within a specific genre, like the Milford Writers Workshop.[3]

[1] ICCC is the key international conference for research in computational creativity.

[2] `http://mnwriters.org/how-the-game-works/`

[3] `http://www.milfordsf.co.uk/about.htm`

The practices that Gabriel describes are fairly typical:

- Authors come with work ready to present, and read a short sample.
- This work is generally work in progress (and workshopping is meant to help improve it). Importantly, it can be early stage work. Rather than presenting a created artefact only, activities in the workshop can be aspects of the creative process itself. Indeed, the model we present here is less concerned with after-the-fact assessment than it is with dealing with the formative feedback that is a necessary support for creative work.
- The sample work is then discussed and constructively critiqued by attendees. Presenting authors are not permitted to rebut these comments. The commentators generally summarise the work and say what they have gotten out of it, discuss what worked well in the piece, and talk about how it could be improved.
- The author listens and may take notes; at the end, he or she can then ask questions for clarification.
- Generally, non-authors are either not permitted to attend, or are asked to stay silent through the workshop, and perhaps sit separately from the participating authors/reviewers.[4]

Essentially, the Writers Workshop is somewhat like an interactive peer review. The underlying concept is reminiscent of Bourdieu's *fields of cultural production* (Bourdieu, 1993) where cultural value is attributed through interactions in a community of cultural producers active within that field.

## 2.1 Writers Workshop as a computational model

The use of Writers Workshop in computational contexts is not an entirely new concept. In PLoP workshops, authors present design patterns and pattern languages, or papers about patterns, rather than more traditional literary forms like poems, stories, or chapters from novels. Papers must be workshopped at a PLoP or EuroPLoP conference in order to be considered for the *Transactions on Pattern Languages of Programming* journal. A discussion of writers workshops in the language of design patterns is presented by Coplien and Woolf (1997).

The steps in the workshop can be distilled into the following phases, each of which could be realised as a separate computational step in an agent-based model:

1. Author: `presentation`
2. Critic: `listening`
3. Critic: `feedback`
4. Author: `questions`
5. Critic: `replies`
6. Author: `reflections`

[4]Here we present Writers Workshops as they currently exist; however this last point is debatable. Whether non-authors should be able to participate or not is an interesting avenue for experimentation both in human and computational contexts. The workshop dialogue itself may be considered an "art form" whose "public" may potentially wish to consume it in non-participatory ways. Compare the classical Japanese *renga* form (Jin'Ichi, Brazell, & Cook, 1975).

The `feedback` step may be further decomposed into `observations` and `suggestions`. This protocol is what we have in mind in the following discussion of the Writers Workshop.[5]

**Dialogue example**

Note that for the following dialogue to be possible computationally, it would presumably have to be conducted within a lightweight process language. Nevertheless, for convenience, the discussion will be presented here as if it was conducted in natural language. Whether contemporary systems have adequate natural language understanding to have interesting interactions is one of the key unanswered questions of this approach, but protocols such as the one described above are sufficient to make the experiment.

For example, here's what might happen in a discussion of the first few lines of a poem, "On Being Malevolent". As befitting the AI-theme of this workshop, "On Being Malevolent" is a poem written by an early user-defined flow chart in the FloWr system (known at the time as Flow) (Colton & Charnley, 2014).

> FLOW: "*I hear the souls of the damned waiting in hell. / I feel a malevolent spectre hovering just behind me / It must be his birthday*."
>
> SYSTEM A: I think the third line detracts from the spooky effect, I don't see why it's included.
>
> SYSTEM B: It's meant to be humourous – in fact it reminds me of the poem you presented yesterday.
>
> MODERATOR: Let's discuss one poem at a time.

Even if, perhaps and especially because, "cross-talk" about different poems bends the rules, the dialogue could prompt a range of reflections and reactions. System A may object that it had a fair point that has not been given sufficient attention, while System B may wonder how to communicate the idea it came up with without making reference to another poem. Here's how the discussion given as example in Section 2 might continue, if the systems go on to examine the next few lines of the poem.

> FLOW: "*Is God willing to prevent evil, but not able? / Then he is not omnipotent / Is he able, but not willing? / Then he is malevolent.*"
>
> SYSTEM A: These lines are interesting, but they sound a bit like you're working from a template, or like you're quoting from something else.
>
> SYSTEM B: Maybe try an analogy? For example, you mentioned birthdays: you could consider an analogy to the conflicted feelings of someone who knows in advance about her surprise birthday party.

[5]The connections between Writers Workshops and design patterns, noted above, appear to be quite natural, in that the steps in the workshop protocol roughly parallel the typical components of design pattern templates: *context*, *problem*, *solution*, *rationale*, *resolution of forces*.

Figure 1: A paper prototype for applying the *Successful Error* pattern following a workshop-like sequence of steps

This portion of the discussion shifts the focus of the discussion onto a line that was previously considered to be spurious, and looks at what would happen if that line was used as a central metaphor in the poem.

> FLOW: Thank you for your feedback. My only question is, System B, how did you come up with that analogy? It’s quite clever.
> SYSTEM B: I’ve just emailed you the code.

Whereas the systems were initially reviewing poetry, they have now made a partial genre shift, and are sharing and remixing code. Such a shift helps to get at the real interests of the systems (and their developers). Indeed, the workshop session might have gone better if the systems had focused on exchanging and discussing more formal objects throughout.

### 2.2 How the Writers Workshop can lead to computational serendipity

Learning involves engaging with the unknown, unfamiliar, or unexpected and synthesising new understanding (Deleuze, 2004 [1968]). In the workshop setting, learning can develop in a number of unexpected ways, and participating systems need to be prepared for this. One way to evaluate the idea of a Writers Workshop is to ask whether it can support learning that is in some sense *serendiptious*, in other words, whether it can support discovery and creative invention that we simply couldn’t plan for or orchestrate in another way.

Figure 1 shows a paper prototype showing how one of the “patterns of serendipity” that were collected by Van Andel (1994) might be modelled in a workshop-like dialogue sequence. The patterns also help identify opportunities for serendipity at several key steps in the workshop sequence.

**Serendipity Pattern: *Successful error*.** Van Andel describes the creation of Post-it™ Notes at 3M. One of the instrumental steps was a series of internal seminars in which 3M employee Spencer Silver described an invention he was sure was interesting, but was unsure how to turn into a useful product: weak glue. The key prototype that came years later was a sticky bookmark, created by Arthur Fry. In the Writers Workshop, authors similarly have the opportunity to share things that they find interesting, but that they are not certain about. The author may want to ask a specific question about their creation: Does $x$ work better than $y$? They may flag certain parts of the work as especially problematic. They may think that a certain portion of the text is interesting or important, without being sure why. Although there is no guarantee that a participating critic will be able to take these matters forward, sometimes they do – and the workshop environment will produce something that the author wouldn’t have thought of alone.

**Serendipity Pattern: *Outsider*.** Another example from van Andel considers the case of a mother whose son was aflicted by a congenital cateract, who suggested to her doctor that rubella during pregnancy may have been the cause. In the workshop setting, someone who is not an “expert” may come up with a sensible idea or suggestion based on their own prior experience. Indeed, these suggestions may be more sensible than the ideas of the author, who may be to close to the work to notice radical improvements.

**Serendipity Pattern: *Wrong hypothesis*.** A third example describes the discovery that lithium can have a therapeutic effect in cases of mania. Originally, lithium carbonate had merely been used a control by John Cade, who was interested in the effect of effect of uric acid, present in soluble

lithium urate. Cade was searching for causal factors in mania, not therapies for the condition: but he found that lithium carbonate had an unexpected calming effect. Similarly, in the workshop, the author may think that a given aspect of their creation is the interesting "active ingredient," and it may turn out that another aspect of the work is more interesting to critics. Relatedly, the author may not fully comprehend a critic's feedback and may have to ask follow-up questions to understand it.

**Serendipity Pattern:** ***Side effect.*** A fourth example described by van Andel concerns Ernest Huant's discovery that nicotinamide, which he used to treat side-effects of radiation therapy, also proved efficacious against tuberculosis. In the workshop setting, one of the most important places where a side-effect may occur concerns feedback from the critic to the author. In the simple case, feedback may trigger revisions to the work under discussion. In a more general, and more unpredictable case, feedback may trigger broader revisions to the generative codebase.

This collection of patterns shows the likelihood of unexpected results coming out of the communication between author and critics. This suggests several guidelines for system development, which we will discussed in a later section.

Further guidelines for structuring and participating in traditional writers workshops are presented by Linda Elkin in (Gabriel, 2002, pp. 201–203). It is not at all clear that the same ground rules should apply to computer systems. For example, one of Elkin's rules is that "Quips, jokes, or sarcastic comments, even if kindly meant, are inappropriate." Rather than forbidding humour, it may be better for individual comments to be rated as helpful or non-helpful. Again, in the first instance, usefulness and interest might be judged in terms of explicit criteria for serendipity; see (Corneli, Pease, Colton, Jordanous, & Guckelsberger, 2014; Pease, Colton, Ramezani, Charnley, & Reed, 2013). The key criterion in this regard is the *focus shift*. This is the creation of a novel problem, comprising the move from discovery of interesting data to the invention of an application. This process is distinct from identifying routine errors in a written work. Nevertheless, from a computational standpoint, noticing and being robust to certain kinds of errors is often a preliminary step. For example, the work might contain a typo, grammatical or semantic error, while being logically sound. In a programming setting, this sort of problem can lead to crashing code, or silent failure. In general communicative context, argumentation may be logically sound, but not practically useful or poorly exposited. Finally, even a masterful, correct, and fully spellchecked piece of argumentation may not invite further dialogue, and so may fail to open itself to further learning. Identifying and engaging with this sort of deeper issue is something that skillful workshop participants may be able to do. Dialogue in the workshop can build on strong or less strong work – but provoking interpretative thoughts and comments always require a thoughtful critical presence and the ability to engage. This can be difficult for humans and poses a range of challenges for computers – but also promises some interesting results.

# 3 Related work

In considering the potential and contribution of the Writers Workshop model outlined in Section 2, we posit that the Writers Workshop model is useful for encouraging feedback in computational systems, and in particular systems that are designed to be creative or serendipitous.

Feedback has long been a central concept in AI-related fields such as cybernetics (Ashby, 1956; Seth, 2015). Feedback about feedback (and &c for higher orders) is understood to be relevant to thinking about *learning* and *communication* (Bateson, 1972). We now consider the importance of the roles that communicative feedback play in computational creativity and computational serendipity and discuss previous related work in incorporating feedback into such computational systems.

## 3.1 Feedback in computational creativity

*Creativity* is often envisaged as involving cyclical processes (e.g. Dickie's (1984) art circle, Pease and Colton's (2011) Iterative Development-Expression-Appreciation model). There are opportunities for embedded feedback at each step, and the creative process itself is "akin to" a feedback loop. However, despite these strong intimations of the central importance of feedback in the creative process, our sense is that feedback has not been given a central place in research on computational creativity. In particular, current systems in computational creativity, almost as a rule, do *not* consume or evaluate the work of other systems.[6]

Gervás and León (2014) theorise a creative cycle of narrative development as involving a Composer and an Interpreter, in such a way that the Composer has internalised the interpretation functionality. Individual creativity is not the poor relation of social creativity, but its mirror image. Nevertheless, even when computer models explicitly involve multiple agents and simulate social creativity (like Saunders & Gero, 2001), they rarely make the jump to involve multiple systems. The "air gap" between computationally creative systems is very different from the historical situation in human creativity, in which different creators and indeed different cultural domains interact vigorously (Geertz, 1973).

## 3.2 Feedback in computational serendipity

The term computational serendipity is rather new, but its foundations are well established in prior research.

Grace and Maher (2014) examine *surprise* in computing, seeking to "adopt methods from the field of computational creativity [...] to the generation of scientific hypotheses." This is an example of an effort focused on computational *invention*.

An area of AI where serendipity can be argued to play an important part is in pattern matching. Current computer programs are able to identify known patterns and "close matches" in data sets from certain domains, like music (Meredith, Lemström, & Wiggins, 2002). Identifying known

[6] An exception to the rule is Mike Cook's AppreciationBot (`https://twitter.com/AppreciationBot`), which is a reactive automaton that "appreciates" tweets from MuseumBot.

patterns is a special case of the more general concept of *pattern mining* (Bergeron & Conklin, 2007). In particular, the ability to extract *new* higher order patterns that describe exceptions is an example of "learning from feedback." Deep learning and evolutionary models increasingly use this sort of idea to facilitate strategic discovery (Samothrakis & Lucas, 2011). Similar ideas are considered in business applications under the heading "process mining" (Van Der Aalst, 2011).

In earlier work (Corneli et al., 2014, 2015), we used the idea of dialogue in a Writers Workshop framework to sketch a "theory of poetics rooted in the making of boundary-crossing objects and processes" and described (at a schematic level) "a system that can (sometimes) make 'highly serendipitous' creative advances in computer poetry" while "drawing attention to theoretical questions related to program design in an autonomous programming context."

### 3.3 Communications and feedback

The Writers Workshop heavily relies on communication of feedback within the workshop. Gordon Pask's conversation theory, reviewed in (Pask, 1984; Boyd, 2004), goes considerably beyond the simple process language of the workshop, although there are structural parallels. We see that a basic Pask-style learning conversation bears many similarities to the Writers Workshop model of communicative feedback (Boyd, 2004, p. 190):

1. Conversational participants are carrying out some actions and observations;
2. Naming and recording what action is being done;
3. Asking and explaining why it works the way it does;
4. Carrying out higher-order methodological discussion; and,
5. Trying to figure out why unexpected results occured.

Variations to the underlying system, protocol, and the schedule of events should be considered depending on the needs and interests of participants, and several variants can be tried. On a pragmatic basis, if the workshop proved quite useful to participants, it could be revised to run monthly, weekly, or continuously.[7]

## 4 Case study: Flowcharts and Feedback

This section describes work that is currently underway to implement the Writers Workshop model, not only within one system but as a new paradigm for collaboration among disparate projects. In order to bring in other participants, we need a neutral environment that is not hard to develop for: the FloWr system mentioned in Section 2.1 offers one such possibility. The basic primary objects in the FloWr system are *flowcharts*, which are comprised of interconnected *process nodes* (Charnley, Colton, & Llano, 2014; Colton & Charnley, 2014). Process nodes specify input and output types, and internal processing can be implemented in Java, or other languages that interoperate with the JVM, or by invoking external web services. One of the common applications to date is to generate computer poetry, and we will focus on that domain here.

A basic set of questions, relative to this system's components, are as follow:

1. *Population of nodes*: What can they do? What do we learn when a new node is added?
2. *Population of flowcharts*: Pease et al. (2013) have described the potentially-serendipitous repair of "broken" flowcharts when new nodes become available; this suggests the need for test-driven development framework.
3. *Population of output texts*: How to assess and comment on a generated poetic artefact?

In a further evolution of the system, the sequence of steps in a Writers Workshop could itself be spelled out as a flowchart. The process of reading a poem could be conceptualised as generating a semantic graph (Harrington & Clark, 2007; Francisco & Gervás, 2006). Feedback could be modelled as annotations to a text, including suggested edits. These markup directives could themselves be expressed as flowcharts. A standardised set of markup structures may partially obviate the need for strong natural language understanding, at least in interagent communication. Thus, we could agree that `observations` will consist of stand-off annotations that connect textual passages to public URIs using a limited comparison vocabulary, and `suggestions` will consist of simple stand-off line-edits, which may themselves be marked up with rationale. These restrictions, and similar restrictions around constrained turn-taking, could be progressively widened in future versions of the system. The way the poems that are generated, the models of poems that are created, and the way the feedback is generated, all depend on the contributing system's body of code and prior experience, which may vary widely between participating systems. In the list of functional steps below, all of the functions could have a subscripted "$\mathcal{E}$", which is omitted throughout. Exchanging path dependent points of view will tend to produce results that are different from what the individual participating systems would have come up with on their own.

I. Both the author and critic should be able to work with a model of the text. Some of the text's features may be explicitly tagged as "interesting." Outstanding questions may possibly be brought to the attention of critical listeners, e.g. with the request to compare two different versions of the poem (`presentation`, `listening`).
   1. *A model of the text.* $m : T \to M$.
   2. *Tagging elements of interest.* $\mu : M \to I$.

II. Drawing on its experience, the critic will use its model of the poem to formulate feedback (`feedback`).
   1. *Generating feedback.* $f : (T, M, I) \to F$.

[7] For a comparison case in computer Go, see `http://cgos.computergo.org/`.

III. Given the constrained framework for feedback, statements about the text will be straightforward to understand, but rationale for making these statements may be more involved (`questions`, `replies`).

   1. *Asking for more information.* $q : (M, F, I) \rightarrow Q$.
   2. *Generating rationale.* $a : (M, F, Q) \rightarrow \Delta F$.

IV. Finally, feedback may affect the author's model of the world, and the way future poems are generated (`reflection`).

   1. *Updating point of view.* $\rho : (M, F) \rightarrow \Delta \mathcal{E}$.

The final step is perhaps the most interesting one, since it invites us to consider how individual elements of feedback can "snowball" and go beyond line-edits to a specific poem to much more fundamental changes in the way the presenting agent writes poetry. Here methods for pattern mining, discussed in Section 3.2, are particularly relevant. If systems can share code (as in our sample dialogue in Section 2.1) this will help with the rationale-generating step, and may also facilitate direct updates to the codebase. However, shared code may be more suitably placed into the common pool of resources available to FloWr than copied over as new "intrinsic" features of an agent.

Although different systems with different approaches and histories are important for producing unexpected effects, "offline" programmatic access to a shared pool of nodes and existing flowcharts may be useful. Outside of the workshop itself, agents may work to recombine nodes based on their input and output properties to assemble new flowcharts. This can potentially help evaluate and evolve the population of nodes programmatically, if we can use this sort of feedback to define fitness functions. The role of temporality is interesting: if the workshop takes place in real time, this will require different approaches to composition that takes place offline (Perez, Samothrakis, Lucas, & Rohlfshagen, 2013). Complementing these "macro-level" considerations, it is also worth commenting on the potential role of "micro-level" feedback within flowcharts. Local evaluation of output from a predecessor node could feed backwards through the flowchart, similar to backpropagation in neural networks. This would rely on a reduced version of the functional schema described above.

## 5 Concluding discussion and future directions

We have described a *general* and *computationally feasible* model for using feedback in AI systems, particularly creative systems. The Writers Workshop concept, borrowed from creative writing, is transformed into a model of a structured approach to eliciting, processing and learning from feedback. To better evaluate how the Writers Workshop model helps us advance in our goal of incorporating feedback into artificial creativity, we critically considered how the model fits into related work. In particular, we found that serendipity, a key concept within creativity and AI more generally, is a concept with which the Writers Workshop model could assist computational progress. In this respect, we should highlight the difference between "global" analytics describing the collection of nodes and flowcharts in the FloWr ecosystem, and the path-dependent process of analysis and synthesis that takes place in a workshop setting.

Our preliminary implementation work (Section 4) shows that the model can be transfered to a functional implementation. This work highlights several considerations relevant to further work with the Writers Workshop model:

- Each contributing system should come to the workshop with at least a basic awareness of the workshop protocol, with work to share, and prepared to give constructive feedback to other systems.
- The workshop itself needs to be prepared, with a suitable communication platform and a moderator or global flowchart for moving the discussion from step to step.
- A controlled vocabulary for communications and interaction would be a worthwhile pursuit of future research, perhaps based on an ontology inspired by the Interaction Network Ontology.[8]
- In order to get the most value out of the workshop experience, systems (and their wranglers) should ideally have questions they are investigating. As discussed above, prior experience plays an important role in every step. This opens up a range of issues for further research on modeling motivations and learning from experience.
- Systems should be prepared to give feedback, and to carry out evaluations of the helpfulness (or not) of feedback from other systems and of the experience overall.

Developing systems that could successfully navigate this collaborative exercise would be a significant advance in the field of computational creativity. Since the experience is about learning rather than winning, there is little motivation to "game the system" (cf. Lenat, 1983). Instead the emphasis is squarely upon mutual benefit: computational systems helping to develop each other through communication and feedback.

The benefits of the Writers Workshop approach could innovate well beyond models for feedback and communication within a particular environment or restricted domain. Following the example of the Pattern Languages of Programming (PLoP) community, we propose that the Writers Workshop model could be deployed within the Computational Creativity community to design a workshop in which the participants are computer systems instead of human authors. The annual International Conference on Computational Creativity (ICCC), now entering its sixth year, could be a suitable venue.

Rather than the system's creator presenting the system in a traditional slideshow and discussion, or a system "Show and Tell," the systems would be brought to the workshop and would present their own work to an audience of other systems, in a Writers Workshop format. This could be accompanied by a short paper for the conference proceedings written

[8] The Interaction Network Ontology primarily describes interactions within humans as opposed to within human societies; a distinct *Social* Interaction Ontology does not seem to exist at present. However, the classes of the Interaction Network Ontology appear to be quite broadly relevant. This ontology is documented at `http://www.ontobee.org/browser/index.php?o=INO`. Its URI is `http://svn.code.sf.net/p/ino/code/trunk/src/ontology/INO.owl`.

by the system's designer describing the system's current capabilities and goals. If the Workshop really works well, future publications might adapt to include traces of Workshop interactions, commentary from a system on other systems, and offline reflections on what the system might change about its own work based on the feedback it receives. Paralleling the PLoP community, it could become standard to incorporate the workshop into the process of peer review for the new *Journal of Computational Creativity*.[9] AI systems that review each other would surely be a major demonstration and acknowledgement of the usefulness of feedback within AI.

In closing, we wish to return briefly to the scenario of computer generated feedback in educational contexts that we raised at the beginning of this paper and then set aside. The elements of our functional design for sharing feedback among computational agents has a range of features that continue to be relevant for generating useful feedback with human learners. Students are experience-bound, and a robust approach to formative assessment and feedback should take into account the student's historical experience, so far as this can be known or inferred. In order for feedback, recommendations, and so on to adequately take individual history into account, sophisticated modelling and reasoning would be required. Nevertheless, from the point of view of participating computational agents, a student may simply look like another agent. It is in this regard that computational models of learning from feedback are seen as fundamental.

**Abstract**

We model the mathematical process whereby new mathematical theories are invented. Here we explain the use of conceptual blending for this purpose, and show examples to illustrate the process in action. Our longer-term goal is to support machine and human mathematical creativity.

## Introduction

We are concerned with creativity in mathematics: creativity as evinced by human and artificial mathematicians, individually and collectively.

Work on *conceptual blending* has been much influenced by Fauconnier and Turner (1998, 2002). More recently, the centrality of conceptual blending to creativity has been stressed by Turner (2014), where he writes:

> . . . the human spark comes from our advanced ability to *blend* ideas to make *new* ideas. Blending is the origin of ideas. (Turner, 2014, p 2)

The claim is that blending in this sense is a general human cognitive ability, and as such applies to mathematics, as much as to art, poetry, music and so on (see for example Turner (2005)).

The place of mathematics and the sciences among creative endeavours has been stressed by the literary critic George Steiner:

> It is in mathematics and the sciences that the concepts of creation and of invention, of intuition and of discovery, exhibit the most immediate, visible force.
>
> Steiner (2001, p 145)

Blending involves recognising features common to mathematical concepts, even when expressed in different terminology. The role of mathematical analogy in creative mathematics is well expressed by Weil (1960), and a general plea for analogical reasoning within science in (Arbib and Hesse, 1986).

We are investigating *computational* accounts of mathematical creativity, taking conceptual blending as a key ingredient. The work of Goguen (1999, 2005) has provided a general framework for comparison of conceptual spaces, and computation of blends. This enables the use of richer representation formalisms, and so is closer to contemporary mathematics than previous computational realisations of blending, such as in Pereira (2007).

This paper deals with the creative process in mathematics, as modelled along the lines above. We focus on the use of blending within a single process, searching for blends satisfying some evaluation criteria, from the starting point of some given conceptual spaces.

While cognitive issues are important to us, this paper is focused on issues in representation and representation change; there are however brief comments on cognition in the conclusions.

We start by providing some background, followed by an example to illustrate the components involved in our approach. A historical example based on Georg Cantor's work follows. The most extended example was carried out by a pure mathematician (D. Gómez-Ramírez), working in a domain close to his own; in this case, the blend mechanism threw up some unexpected properties, which provoked new work by the mathematician.

Subsequently we give some more speculative thoughts on where this work can go in the future, by considering Galois theory as a test-bed. Finally, we discuss the evaluation of work along these lines, and give some conclusions.

## Background

### Blending in Mathematics

Lakoff and Núñez (2000) are among the first to present a cognitive account of the origin and development of mathematical ideas,[1] arguing against the "romance of mathematics" in which mathematics is presented as an ever-increasing set of universal, absolute, certain truths which exist independently of humans. They present the thesis that human mathematics is grounded in bodily experience of a physical world, and mathematical entities inherit properties which objects in the world have, such as being consistent or stable over time. Exploring the physical world of object collection might lead to concepts like the empty collection and rules like "adding a collection of $n$ objects to an empty

[1] This is lamented by Lakoff and Núñez, who claim that (prior to their work), "there was still no discipline of mathematical idea analysis from a cognitive perspective" (Lakoff and Núñez, 2000).

collection yields a collection with $n$ objects". People then form grounding metaphors between the physical world and an abstract mathematical world, allowing us to project from everyday experiences onto abstract concepts, thus leading to the concept of zero and the axiom that $n+0 = n$. Lakoff and Núñez posit that blending different mathematical metaphors leads to more complex ideas (see also Alexander (2011)).

Alongside this account of mathematical cognition, mainstream contemporary mathematics has developed its own methodology and foundations, enjoying an exceptional place among scientific disciplines. Its methods, objects of study and sometimes astonishing results have widespread, if not universal, acceptance.

In conclusion, mathematics is a scientific discipline having not only a fundamental cognitive component, necessary in its development, but also possessing a collection of general principles and structures going beyond a particular school of thought. Among these general processes we want to highlight in this paper the importance that conceptual blending has in mathematics, incorporating both cognitive and mathematically specific aspects in order to create new mathematical concepts.

## Terminology for conceptual blending

Our notion of conceptual blending is informed by Category theory, and highly influenced by Goguen's work on concepts (Goguen, 2005). In this paper we use the terminology below, and elucidate the terminology by means of a running example – discovering a version of the integers (in the sense of providing a partial approach to the genuine integers) using blending.

**Conceptual spaces** are partial and temporary representational structures which are constructed on the fly when talking about a particular situation, which are informed by the knowledge structures associated with a domain. These are influenced by Boden's idea of a concept space which is mapped, explored and transformed by transcending mapped boundaries (Boden, 1977), and form the input spaces to our blend.

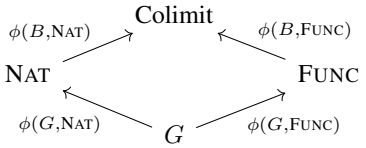
As an example of two conceptual spaces, consider one as a theory NAT – a theory of the natural numbers, and FUNC – a theory of a total unary function with an inverse. We will refer back to these theories in this exposition.

(Many-sorted) First-order **Axioms** are the criteria which will be used here to delineate the conceptual spaces. The axiomatic method has been a fundamental aspect of mathematical research since Euclid, and various axiom changes have led to revolutions in mathematics. For instance, rejecting the parallel postulate opened up fascinating new areas of non-Euclidean geometry.

The precise formulations for NAT and FUNC can be found in Listings 1 and 2. Notice that these formulations obviously refer to partial representations of the genuine concepts employed by mathematicians. In the conceptual space with theory NAT, an example of an axiom is $\forall x.\neg\ 0 = s(x)$ – that is that zero is not a successor element. The conceptual space with theory FUNC has an axiom $\forall x.\ f(finv(x)) = x$.

**Signature morphisms** between conceptual spaces are mappings from the symbols of the source conceptual space into the symbols of the other conceptual space. For example NAT contains a function $\lambda x : Nat.\ s(x)$ that maps $x$ to its successor, and FUNC contains a function defined over a set $X$ that maps each element to an image $\lambda x : X.\ f(x)$. A theory $G$ with a morphism to both NAT and FUNC might contain a function $\lambda x : N.\ func(x)$ that takes every number in some set $N$ to its image under *func*. When we show a mapping we write this as

$$s \quad \leftarrow_{\phi(G,\text{NAT})} \quad func \quad \rightarrow_{\phi(G,\text{FUNC})} \quad f \qquad (1)$$



$$Nat \quad \leftarrow_{\phi(G,\text{NAT})} \quad N \quad \rightarrow_{\phi(G,\text{FUNC})} \quad X \qquad (2)$$

The mapping $\phi(G, \text{NAT})$ is a signature morphism from $G$ to NAT. Note that associated types are also mapped.

**Input Spaces** refer to two or more conceptual spaces of interest.

**Generic spaces** are conceptual spaces that possess commonality between input spaces.

**Colimits** are conceptual spaces representing a blend of input spaces with respect to a given generic space and a set of signature morphisms. These are uniquely computed given a generic space and a set of morphisms. Here is a diagrammatic representation of such a computation in our example using theories NAT and FUNC :

The conceptual space represented by the Colimit is often referred to as the *blend*.

**Internal Evaluation** constitutes a variety of techniques to determine whether a computed colimit is viable as a conceptual space. In our example, since the conceptual spaces are mathematical theories, we can exploit the notion of consistency. This is a way of evaluating whether a blend is not only creative, but also valid. In the example of theories NAT and FUNC, the computed blend is inconsistent due to the emergent axioms in the computed colimit. The only type existing within the colimit is from now on referred to as $\mathbb{Z}$ to distinguish it from the natural numbers. Notice that in the colimit it holds that:

$$\forall x : \mathbb{Z}.\neg\ zero = s(x)$$

$$\forall x : \mathbb{Z}.\ s(sinv(x)) = x\ .$$

This is an inconsistency, as from the second axiom we see that there is an element for which 0 is the successor.

**Weakening** refers to the process of weakening the input theories by removing symbols or axioms. If we remove the axiom

$$\forall x : Nat.\neg\ zero = s(x)$$

then the resulting computed colimit contains a mathematical theory which is consistent.

Martinez et al. (2014) provides an algorithm to explore the space of blends resulting from given input spaces and a given generic space, where weakening is achieved by omitting axioms. The algorithm returns the blends which are consistent, and maximally so, among those in this space of

blends. This algorithm assumes that consistency of relevant theories can be checked, so is not always effective.

**Running the blend** refers to elaborating or completing a mathematical theory. Sometimes there are missing definitions which need to be discovered. For example in the new theory the following axiom appears

$$\forall x, y : \mathbb{Z}.\ s(x) + y \quad = \quad s(x + y)\ ,$$

but we also are interested in theorems such as

$$\forall x, y : \mathbb{Z}.\ \mathit{sinv}(x) + y \quad = \quad \mathit{sinv}(x + y)\ .$$

Finding suitable theorems is an example of running the blend, and from which it is possible to discover and prove theorems such as

$$\forall x, y : \mathbb{Z}.\ \mathit{sinv}(x) + s(y) \quad = \quad x + y\ .$$

### Technologies

The approach explained above corresponds to Goguen's proposal (Goguen, 1999) for implementing blending, but slightly simplified (as in Kutz, Neuhaus, Mossakowski, and Codescu (2014)): we use the normal colimit construction, rather than $\frac{3}{2}$-colimits (both described in Goguen (1999)).

Additionally we assume that the conceptual spaces involved are given using a CASL specification (Astesiano et al., 2002) and that the morphisms are theorem preserving (i.e. map theorems to theorems). The reason for these assumptions is that in these cases it is well-known how to compute colimits: the colimit specification essentially corresponds to the disjoint union of the two target conceptual spaces except for not repeating the symbols given in the common source conceptual space. Moreover, we will be using the HETS system (Mossakowski, Maeder, and Lüttich, 2007) to compute such colimits. The code for the implemented examples in this paper is available on-line.[2]

The use of CASL specifications means that we deal with first-order logic; CASL is supported in the HETS system, and colimits here can be computed in the current implementation of HETS. Although higher-order logic (with Henkin semantics) is available in HETS (indeed in CASL) and the colimits are well-known to exist (because higher-order in this form is reducible to many-sorted first-order logic), it is worth noticing that the calculus of such colimits is not currently available in HETS. This restricts the formalisms that can be used directly for our purposes, where computation of colimits is central to our approach.

## Blending and the infinite

### Example Revisited – the Integers

As a first demonstration of the machinery involved in blending mathematical theories, we consider combining a theory of natural numbers with the concept of the inverse of a function to obtain the integers. Let us assume a simple partial axiomatisation of the natural numbers (without order axioms) as shown in Listing 1, and call this theory NAT. Now let us also define a simple theory which introduces the concept of a function with an inverse as shown in Listing 2, and call this theory FUNC.

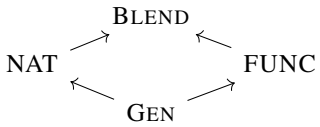
[2] See: https://github.com/ewenmaclean/ICCC2015_hetsfiles

**spec** NAT =
**sort** *Nat*
**ops** *zero* : *Nat*;
*s* : *Nat* → *Nat*;
__+__ : *Nat* × *Nat* → *Nat*
∀ *x*, *y* : *Nat*
• $s(x) = s(y) \Rightarrow x = y$
• $\neg\ zero = s(x)$
• $s(x) + y = s(x + y)$
• $zero + y = y$
**end**

Listing 1: A theory of the natural numbers without order

**spec** FUNC =
**sort** *X*
**op** $f : X \to X$
**op** $\mathit{finv} : X \to X$
∀ *x* : *X*
• $f(\mathit{finv}(x)) = x$
• $\mathit{finv}(f(x)) = x$
**end**

Listing 2: A theory with a function and its inverse defined



**Identifying a Generic Space** In order to incorporate the notion of blending here we want to be able to identify a "generic" component of each theory and compute the colimit. We can use the HDTP system (Gust, Kühnberger, and Schmidt, 2006; Schmidt, 2010) to discover a common theory and signature morphism between symbols in the two theories NAT and FUNC. The Generic theory GEN contains a sort *N* and a function *func*, and the morphisms from the Generic theory to NAT and FUNC are:

$$s \quad \leftarrow_{\phi(G,\mathrm{NAT})} \quad \mathit{func} \quad \rightarrow_{\phi(G,\mathrm{FUNC})} \quad f \qquad (3)$$

$$\mathit{Nat} \quad \leftarrow_{\phi(G,\mathrm{NAT})} \quad N \quad \rightarrow_{\phi(G,\mathrm{FUNC})} \quad X \qquad (4)$$

Here the successor function is identified in the mapping with the function in the theory FUNC.

**Computing the Colimit** The HETS system (Mossakowski et al., 2007) can then be exploited to find a new theory by computing the colimit:

This generates the theory shown in Listing 3 (for the sake of understanding it is used *p*, for predecessor, instead of *sinv*).

**Removal of Inconsistencies** This theory is automatically determined to be inconsistent due to the axioms

$$\forall x : \mathbb{Z}.\neg\ zero = s(x) \qquad (5)$$

$$\forall x : \mathbb{Z}.\ s(p(x)) = x \qquad (6)$$

**spec** SPEC =
**sort** $N$
**op** $_+_ : N \times N \to N$
**op** $p : N \to N$
**op** $s : N \to N$
**op** $zero : N$
$\forall x, y : N \bullet s(x) = s(y) \Rightarrow x = y$
$\forall x : N \bullet \neg\, zero = s(x)$
$\forall x, y : N \bullet s(x) + y = s(x + y)$
$\forall y : N \bullet zero + y = y$
$\forall x : N \bullet s(p(x)) = x$
$\forall x : N \bullet p(s(x)) = x$
**end**

Listing 3: An inconsistent partial approach to the integers (without order)

Removal of the limiting axiom (5) from Listing 1 results in generating a blend theory which is very similar to what we understand to be the integers as shown in Listing 4.

**spec** SPEC =
**sort** $N$
**op** $_+_ : N \times N \to N$
**op** $p : N \to N$
**op** $s : N \to N$
**op** $zero : N$
$\forall x, y : N \bullet s(x) = s(y) \Rightarrow x = y$
$\forall x, y : N \bullet s(x) + y = s(x + y)$
$\forall y : N \bullet zero + y = y$
$\forall x : N \bullet s(p(x)) = x$
$\forall x : N \bullet p(s(x)) = x$
**end**

Listing 4: A consistent partial approach to the integers (without order)

**Running the Blend** Running the blend refers to discovering definitions or adding axioms to flesh out the blend. In the example of the version in Listing 4, the definition of plus needs to be extended to understand how to calculate with the predecessor function:

$$p(x) + y = p(x + y)$$

from which theorems such as

$$p(x) + s(y) = x + y$$

can be proved.

## Potential and actual infinity

Some of the ideas of Lakoff and Núñez (2000) have been reworked by the authors, with increased emphasis on conceptual blending. In particular, the analysis of mathematical infinity, given in metaphorical form as the "Basic Metaphor of Infinity" (BMI) in Lakoff and Núñez (2000), is represented in blend form in Núñez (2005) as the "Basic Mapping of Infinity" (so, still "BMI").

We show here how this blend works out in our setting. The BMI suggests that the notion of completed infinity, in particular the possibility of transfinite numbers in the sense of Cantor, comes from a blend of the notion of completed, finite process with that of a potentially infinite and endless process.

Thus take two corresponding input spaces, given by CASL specifications **FinEnd** and **Inf** corresponding to the following diagrams

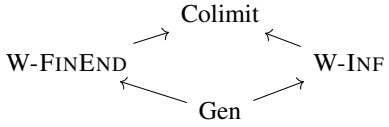
**FinEnd:**

**Inf:**

- **FinEnd:** Completed Iterative Processes are those that from some initial state, terminate in a final state after a finite number of state transitions. One such case is chosen.
- **Inf:** Infinite Iterative Processes are those that continue indefinitely to change state.

In both cases, the arrows indicate steps of the processes, and the process states are in a discrete linear order indicated by left-to-right order in the diagrams.

The generic space **Gen** simply identifies the start states, the notion of process step, and the linear ordering of states.



Now we can compute the blend of these spaces, which includes new features taken from both of the input spaces. This blend is *inconsistent*, for the following two reasons:

1. the number of states is finite (from **FinEnd**), and infinite (from **Inf**);
2. there both is an end state (from **FinEnd**) and is no end state (from **Inf**).

Search through the possibilities of weakening the input spaces by omitting as few axioms as possible among those involved in an inconsistency reveals the possibility of a structure with infinitely many states (from **Inf**) and an end state (from **FinEnd**). Computing the colimit from the weakened input spaces **W-FinEnd**, **W-Inf** gives a theory corresponding to this diagram:

Thus we have a blend as in the earlier examples:

## Prime Ideals as a blend

### Introduction

One of the most fundamental concepts of modern mathematics, which is the basis of commutative algebra and a seminal ingredient of the language of schemes in modern algebraic

geometry, is that of *prime ideal* (Grothendieck and Dieudonné, 1971; Eisenbud, 1995).

The terminology "prime ideal" relates to the older notion of "prime number". The initial aim of this work was to look for a blend between prime numbers (from the integers) and the ideals of a commutative ring, to see what would emerge. It turned out that *the blend process*, along with providing a definition for prime ideals, also *suggested an unexpected concept in the context of rings*, namely what will be called Containment Division Rings (CDR). In turn, this prompted questions and proofs about this concept – thus running the blend (space prevents description of this step in this paper).

We present a first blend involving weakening, followed by a second blend from fuller input spaces, where the emergent concept of CDR appears.

## The first conceptual space

Let $(R, +.*, 0, 1)$ be a commutative ring with unity (see the formal definition and examples in Eisenbud (1995)). Now, $R$ can be understood as the sort containing the elements of the corresponding commutative ring with unity. An ideal $I$ is a subset of $R$ satisfying the following axiom:

$$(\forall i, j \in I)(\forall r \in R)(i + (-j) \in I \wedge r * i \in I).$$

Let us define a unary relation (predicate) *isideal* on the set (sort) of subsets of $P(R)$ corresponding to this definition. Now, we define

$$\mathrm{Id}(R) = \{A \in P(R) : \mathit{isideal}(A)\}.$$

Ideals are "multiplied" using the following definition:

$$I \cdot_\iota J = \left\{ \sum_{k=1}^{n} i_k \cdot j_k : n \in \mathbb{N} \wedge i_1, \ldots, i_n \in I \wedge j_1, \ldots, j_n \in J \right\}.$$

In other words, $I \cdot_\iota J$ is the smallest ideal extending the set $\{i \cdot j : i \in I \wedge j \in J\}$.

The key property that we want to keep in the blend is the one saying that this operation $\cdot_\iota$ has a neutral element $1_\iota$, which can be seen as an additional notation for the ring. On the other hand, we want to see the containment relation $\subseteq$ as a binary relation over the sort $\mathrm{Id}(R)$.

Summarizing, our first conceptual space consists of sorts $R, \mathrm{Id}(R)$ and $P(R)$; operations $+, *, 0_R, 1_R, 1_\iota$ and $\cdot_\iota$; and the relations $\subseteq$ and *isideal*.

Let us denote this space by $\mathbb{I}$.

## The second conceptual space

Let $\mathbb{Z}$ be the set of the integer numbers. Here, we choose any partial axiomatization of them including at least the fact that $(\mathbb{Z}, *, 1)$ is a commutative monoid. We define also an upside-down divisibility relation $\lfloor$ defined as $e \lfloor g := g|e$, i.e. there exists an integer $c$ such that $e = c * g$. Let us define a unary relation *isprime* on $\mathbb{Z}$ as follows: for all $p \in \mathbb{Z}$, $\mathit{isprime}(p)$ holds if $p \neq 1$ and:

$$(\forall a, b \in \mathbb{Z})\ \big((ab \lfloor p) \rightarrow (a \lfloor p \vee b \lfloor p)\big).$$

Besides, we define the set (sort) of the prime numbers as

$$\mathit{Prime} = \{p \in \mathbb{Z} : \mathit{isprime}(p)\}$$

In the CASL language, we consider $\mathbb{Z}$ as the sort of the integer numbers, $*$ as a binary operation, *prime* as a predicate and $\lfloor$ as a binary relation, any of them defined over the sort $\mathbb{Z}$. We denote this conceptual space by $\mathbb{P}$.

## The Generic Space

The generic space $\mathbb{G}$ consists of a set (sort) $G$ with a binary operation $*_G$, a neutral element $S$ and a binary relation $\leq_G$.

## The Blending Morphisms

The morphism to $\mathbb{I}$ uses:
$\varphi(G) = \mathrm{Id}(R), \varphi(*_G) = *_\iota, \varphi(S) = 1_\iota$ and $\varphi(\leq_G) = \subseteq$;
the morphism to $\mathbb{G}$ uses:
$\delta(G) = \mathbb{Z}, \delta(*_G) = *, \delta(S) = 1$ and $\delta(\leq_G) = \lfloor$.

## The Axiomatization of the Blending

A straightforward colimit construction based on the input and generic spaces above yields a consistent space with properties inherited both from the prime elements into the integers and from the ideals of commutative rings; one of the concepts is a notion of prime ideals, another is that of CDR.[3] Here we describe briefly a weakening of the given spaces that makes the resultant blend more generally applicable.

From the properties defining the integers we transfer into the blend only the fact that $\mathbb{Z}$ is a set with a binary operation $*$ having 1 as neutral element and $\lfloor$ as a binary relation, without taking into account its formal definition.

Now after computing the colimit, we obtain that any element $P \in G$ (i.e., an ideal of $S$) satisfies the predicate *isprime* if and only if

$$P \neq S \wedge (\forall X, Y \in G = \mathrm{Id}(S))(X \cdot_\iota Y \subseteq P \rightarrow (X \subseteq P \vee Y \subseteq P)).$$

Thus, the predicate *isprime* turns out to be the predicate characterizing the primality of ideals of $S$ and the set (sort) $Prime$ turns out to be the set of prime ideals of $S$.

Using the weakened input spaces, the blending space consists of the axioms assuring that $S$ is a commutative ring with unity, $G$ is the set of ideals of $S$, *isprime* is the predicate specifying primality for ideals of $S$ and *Prime* is the collection of all prime ideals of $S$.

## Implementation for prime ideals over CDR-s as a blend

In this section we construct the concept of prime ideal over a CDR as a blend of the conceptual space of ideals of a commutative ring with unity and the conceptual space of the former second conceptual space where the axiom defining the upside-down divisibility relation is restored.

It is worth mentioning again that the definition of CDR-s was obtained after doing this implementation and therefore it could be seen as a form of "creative" result coming from the blending process.

After computing the corresponding colimit in HETS and interpreting "RingElt" as the sort containing the elements of the ring $S$, the theory defining the blend corresponds to the axioms defining a CDR (*S*), the set of all its ideals (*Generic*), the set all its prime ideals (*SimplePrime*) and a primality predicate (*IsPrime*). We present in Listing 5 just the

[3] A ring $R$ is a Containment Division Ring (CDR) if for all ideals $I$ and $J$ of $R$, $I \subseteq J$ if and only if $J$ divides $I$ (i.e. there exists an ideal $U$ such that $I = U \cdot_\iota J$).

theory corresponding to the colimit (omitting details of ring axioms and ideal generation).

```
spec SPEC =
    sorts Generic, RingElt, SimplePrime, SubSetOfRing

        ∧ ¬ p = S
end
```

Listing 5: Colimit for prime ideals over CDR-s

## A Challenge Example for Blending

### Computational Creativity via Blending

The examples shown thus far in the paper have been examples of blending in mathematics whose mechanisation has helped to identify some novel and unexpected results. The blending itself was a one-stage process where human input was required to identify the input concepts. A more ambitious aim of the approach of applying blending to the problem of computational creativity in mathematics, is to allow search to be done over multiple blends and for the *process* of blending to be controlled mechanically. In this section we describe very informally a mathematical domain that seems in some ways a natural candidate for a blending approach.

### Galois Theory

Galois theory develops a relationship between a polynomial $p(x)$ with coefficients in some field $F$, the extension of $K$ of $F$ (written "$K/F$") containing all of the roots of $p(x)$ in the algebraic closure of $F$, and the group $\mathbf{Gal}(K)$ of automorphisms of $K/F$ that fix the elements of $F$. The fundamental theorem of Galois theory states that there is a bijection between the subfields of $K/F$ and the subgroups of $\mathbf{Gal}(K)$; namely, subgroups correspond to their fixed fields. Using this correspondence, properties of polynomials can be derived, most famously the fact that quintic polynomials cannot be solved by algebraic operations and the extraction of roots.

We do not propose to reconstruct much of the theory here, but note that already in this basic account there are several steps that seem compellingly "blend-like."

In the first place, for field extension, $E$ is an extension of $F$ if $F$ is a subfield of $E$. We could derive the extension relationship from the input concepts $E$ and $F$ by "taking everything additional from $E$ and adding it to $F$." This is made specific in the process of *adjoining* elements, which simply means to augment the field with all fractions of formal finite sums and products of the adjoined elements with coefficients in the base field.

Second, the notion of the *splitting field* of a polynomial, namely the special extension $K/F$ containing all of the roots of $p(x)$. This could be formed conceptually by combining the concept "*the roots of a polynomial $p(x)$ with coefficients in a field $F$*" and the concept "*a field extension $E/F$ formed by adjoining certain elements to $F$*."

As above, we could then form the concept of $\mathbf{Gal}(K)$ by blending at the conceptual level. This time, there would be several constituent pieces: "*the roots of a polynomial $p(x)$ with coefficients in a field $F$*," "*the splitting field of $p(x)$*," "*the group of automorphisms of a field extension $E$*," "*the automorphisms that fix $F$*."

Finally, assuming that we have built $\mathbf{Gal}(K)$ in this fashion, we would like to know some of its properties. Consider the claim that *elements of $\mathbf{Gal}(K)$ permute the roots of $f$*. This time, instead of being purely conceptual, we want to work at the *process* level, and consider before-and-after descriptions of the result of applying $\varphi \in \mathbf{Gal}(K)$ to some $r$ with the property $p(r) = 0$. This is similar in some ways to the "Riddle of the Buddhist Monk", popularised by Koestler (1964), which is cited as an example of the power of blending.[4] However, this time the generic space is not a simple geometric machine, but rather an algebraic machine with several moving parts.

The proof of the claim is as follows. If $p(r) = 0$, then $\varphi p(r) = \varphi 0$. Since $\varphi$ is an automorphism, $\varphi 0 = 0$; and furthermore $\varphi$ distributes over the sums and products that make up the polynomial $p(x)$ and fixes its coefficients, therefore $\varphi p(r) = p(\varphi r)$. Chaining the equalities together, we have $p(\varphi r) = 0$.

[4] "A Buddhist monk begins at dawn one day walking up a mountain, reaches the top at sunset, meditates at the top for several days until one dawn when he begins to walk back to the foot of the mountain, which he reaches at sunset. Making no assumptions about his starting or stopping or about his pace during the trips, prove that there is a place on the path which he occupies at the same hour of the day on the two separate journeys."

In short, the proof is a fairly direct result of combining the definitions. Goguen (1992) suggests that "combination is colimit." Can we realise the proof through (one or several) colimit operations? And is there anything special about this proof? Apart from these more theoretical questions, the foregoing discussion raises the following technical issues:

**Field Extension** When reasoning about polynomials, it is useful to distinguish the three separate types – those of $E$, those of $F$ and those of $E/F$ as a supertype. Using blending machinery removes the distinction between these types.

**Splitting Field Extension Theorem** A challenging but creative step is to discover the theorem that extending $F$ *only* with the roots of $f(x)$ forms a field.

**Automorphisms** As mentioned in the background section, currently there is no way of computing colimits if automorphisms are characterised in higher-order logic. An alternative specification, or an implementation of colimit computation for higher-order logic is needed.

## Evaluation and Outlook

### Review of the current offering

(a) We began the paper with the reconstruction of certain mathematical objects, showing the technical feasibility of the approach.

(b) The more advanced example at the centre of the paper illustrates how this sort of reconstruction relates to mathematical practice.

(c) A future-oriented example exposes some technical challenges, while suggesting that blending could offer a novel approach to computer mathematics.

### Broader issues in evaluation

In addition to motivating a further investigation of the role blending can play in proofs, Galois theory, discussed above, is paradigmatic for other reasons. This discussion draws on the early 20th Century writings of Albert Lautman on the philosophy of mathematics and the subsequent interpretation of this work by Gilles Deleuze. It uses these ideas to propose an approach to embedding evaluation within the system itself.

Concerning the common features of Galois theory, class field theory, and the development of the universal covering surface in Riemann geometry, (Lautman, 2011, p. 126) writes:

> What is characteristic of the movement of the theories that will be considered here is the existence of an end conceived in advance as a term of the ascent.

This is reminiscent of our notion of internal evaluation that apply to the blend. To illustrate, let us briefly imagine how we would use blending techniques to move from porcupine+lion to the perfected *porculione*. Here, instead of field automorphisms that preserve mathematical structure and fix certain designated elements, we would look for mappings that preserve other properties that exist in the underlying domain. Porculiones would presumably have four feet, would be mammals, and would be omnivores; they should also be viable living creatures.

(Deleuze, 1994, pp. 227–228) follows Lautman in enthusiastically endorsing the Galoisian approach to mathematics:

> [T]he fact that an equation cannot be solved algebraically, for example, is no longer discovered as a result of empirical research or by trial and error, but as a result of the characteristics of the groups and partial resolvents which constitute the synthesis of the problem and its conditions (an equation is solveable only by algebraic means – in other words, by radicals, when the partial resolvents are binomial equations and the indices of the groups are prime numbers). The theory of problems is completely transformed and at last grounded, since we are no longer in the classic master-pupil situation where the pupil understands and follows a problem only to the extent that the master already knows the solution and provides the necessary adjunctions. For, as Georges Verriest remarks, the group of an equation does not characterise at a given moment what we know about its roots, but the objectivity of what we do not know about them. Conversely, this non-knowledge is no longer a negative or an insufficiency but a rule or *something to be learnt* which corresponds to a fundamental dimension of the object.

Although there is a commonality between blending and the Galoisian approach insofar as progressive refinement carries us toward a "perfected" conclusion, Deleuze's enthusiasm about the pedagogical situation would be significantly cooled here. It would seem, in many of our examples, that we only make progress "to the extent that the master already knows the solution and provides the necessary adjunctions."

However, this apparent infelicity may be less of a thick obstacle than it would initially appear. What seems to be most needed is a notion of a *question* inside the system. This would recover Lautman's basic thrust: "Scientific or not, every question has built in some assumptions about the form of the answer" (Larvor, 2011). In short, an experimental approach in which the system *asks* and *answers* questions would embed key aspects for evaluation in the system itself.

### Future work

The idea of using blending to carry out steps in a proof would provide a useful training ground for further development. The primary problem is: If blending is the realisation of "combinatorial creativity" how will we avoid being swamped by the combinatorial explosion of possible things to combine? The first challenge is thus fitting different mathematical components together in a sensible manner. A related challenge would apply when modifying the system to selectively experiment with the rules it uses. The objective in this case would be for the system to learn to associate different (useful) techniques with different types of problems.

## Conclusions and Remarks

The examples presented in this paper trace the development of the blending approach. The current paper begins with reconstructions, but also quickly shows how computed blends

can suggest new mathematical definitions and concepts of interest to practising mathematicians. The analysis offered here shows that this work is a building block that will be useful for future developments that are able to reason more flexibly about mathematical problems – and systematically find and propose new concepts and problems.

In future work, we will look more at the cognitive issues raised in this work. In particular, the use of *image schemas* can give a link between the computational and representational approach taken here, and the cognitive claims coming from authors such as Fauconnier and Turner, and Johnson. Here the work of Mandler and Canovás (2014) and Hedblom, Kutz, and Neuhaus (2014) gives an idea of how these underlying cognitive primitives can be expressed in logical form, and can thus play an explicit role in our modelling of creativity in mathematics.

## Acknowledgements

The authors are grateful to the referees for constructive comment. The project COINVENT acknowledges the financial support of the Future and Emerging Technologies (FET) programme within the Seventh Framework Programme for Research of the European Commission, under FET-Open Grant number: 611553.

**Abstract**

This paper motivates the use of computational argumentation for evaluating 'concept blends' and other forms of combinatorial creativity. We exemplify our approach in the domain of computer icon design, where icons are understood as creative artefacts generated through concept blending. We present a semiotic system for representing icons, showing how they can be described in terms of interpretations and how they are related by sign patterns. The interpretation of a sign pattern conveys an intended meaning for an icon. This intended meaning is subjective, and depends on the way concept blending for creating the icon is realised. We show how the intended meaning of icons can be discussed in an explicit and social argumentation process modeled as a dialogue game, and show examples of these following the style of Lakatos (1976). In this way, we are able to evaluate concept blends through an open-ended and dynamic discussion in which concept blends can be improved and the reasons behind a specific evaluation are made explicit. In the closing section, we explore argumentation and the potential roles that can play at different stages of the concept blending process.

## Introduction

A proposal by (Fauconnier and Turner, 1998) called *concept blending* has reinvigorated studies trying to unravel the general cognitive principles operating during creative thought. According to (Fauconnier and Turner, 1998), concept blending is a cognitive process that serves a variety of cognitive purposes, including creativity. In this way of thinking, human creativity can be modeled as a blending process that takes different mental spaces as input and blends them into a new mental space called a *blend*. This is a form of *combinatorial creativity*, one of the three forms of creativity identified by Boden (2003). A blend is constructed by taking the existing commonalities among the input mental spaces (called the generic space) into account, and by projecting the structure of the input spaces in a selective way. In general the outcome can have an emergent structure arising from a non-trivial combination of the projected parts. Different projections lead to different blends and different generic spaces constrain the possible projections.

This poses challenges from a computational perspective: large number of possible combinations exhibiting vastly different properties can be constructed by choosing different input spaces, using different ways to compute the generic space, and selecting projections. Within the Concept Invention Theory project[1] (COINVENT), we are currently developing a computational account of concept blending based on insights from psychology, Artificial Intelligence (AI), and cognitive modelling (Schorlemmer et al., 2014). One of our goals is to address this combinatorial nature. One potential outcome of this work is a deeper understanding of the way combinatorial creativity works in general.

The formal and computational model for concept blending under development in COINVENT (Bou et al., 2014) is closely related to the notion of *amalgam* (Ontañón and Plaza, 2010). Amalgamation has its root in case-based reasoning and focuses on the issue of combining solutions coming from multiple cases. Assuming the solution space can be characterised as a generalisation space, the amalgam operation combines input solutions into a new solution that contains as much information from the two inputs solutions as possible. When input solutions cannot be combined, amalgamation generalises them by dropping some of their properties. This process of generalisation and combination can be expensive from a computational point of view, depending on the search space to be explored.

The amalgam-based approach for computing blends makes explicit the combinatorial nature of concept blending, which raises the issue of evaluating and selecting novel and valuable blends as opposed to those combinations that lack interest or significance. Although Fauconnier and Turner (1998) suggest a number of qualitative criteria that can be used for evaluating concept blends, it is not straightforward to chararacterise them in a computational model.

In this paper, we propose to explore an argumentative approach to understanding and evaluating the meaning, interest, and significance of concept blends. Specifically, we propose to view evaluating blends as a process of *argumentation*, in which the specifics of a blend are pinpointed and opened up as issues of discussion. Our intuition is that in the context of new ideas, proposals, or artworks, people use critical discussion and argumentation to understand, absorb and evaluate. We also consider the constructive roles that argumentation can play in concept blending.

Computational argumentation models have recently appeared in AI applications (Bench-Capon and Dunne, 2007;

[1]See `http://www.coinvent-project.eu` for details.

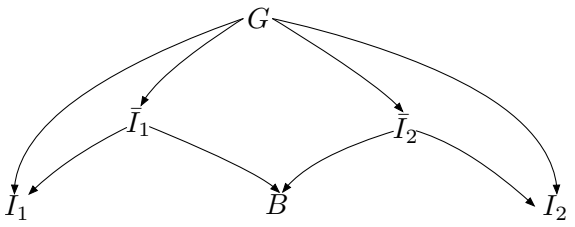

Figure 1: An amalgam diagram with inputs $I_1$ and $I_2$ and blend $B$ obtained by combining $\bar{I}_1$ and $\bar{I}_2$. The arrows indicate generalisation.

Rahwan and Simari, 2009), and we believe that incorporating argumentation can foster the development of a fuller computational account of combinatorial creativity. The current paper develops these themes at the level of (meta-) design; implementation is saved for future work.

### Roles of Argumentation in Concept Blending

Consider the *amalgam* diagram modeling the concept blending process (Figure 1): two input spaces $I_1$, $I_2$, two of their possible generalisations $\bar{I}_1$, $\bar{I}_2$, which have a generic space $G$ and blend $B$. When two input spaces cannot be combined because they do not satisfy certain criteria, the inputs have to be generalised for omitting some of their specifics. The combination of each specific pair $\bar{I}_1$, $\bar{I}_2$ yields a blend.

Informally, we can imagine argumentation taking place at various points in the amalgam diagram. In general this would happen in response to indeterminacy, that is, when some features of the diagram are underdetermined. We foresee that argumentation can be used:

**a.** to express opinions or points of view that can be used for guiding the selection/omission of specific parts of the input spaces; in particular, to select a specific pair of generalisation $\bar{I}_1$, $\bar{I}_2$ of the input spaces in the blending process;

**b.** to provide a computational setting for modeling discussions around the quality of a creative artefact, with the aim of evaluating and refining the generated blends.

In the first case, arguments would be about generalisation, i.e. which features should be preserved from $I_1$ and which features should be preserved from $I_2$. More complex inferences could be involved, for example in a case where $I_1$ is fixed, and constraints and various optimality criteria on the blend are imposed, which then yield various constraints on what the other input $I_2$ should be. We return to this point in the discussion section, and we focus for the most part on the second case.

In the second case, argumentation would be used to evaluate a range of blends, and the evaluation is carried out *post hoc*, by a variation of try-it-and-see. A range of blends are trialled, each one bringing out different (un)intended meanings. The evaluation is modeled as an argument, or dialogue in which the specifics of a blend are pinpointed and opened up as issues of discussion. This dialogue can be considered as an introspective evaluation, although it usually takes place among several parties as a means for the social development and understanding of creative artefacts. In this paper, we focus on this role.

### Our Approach

To exemplify our approach, we take the domain of computer icons into account. We assume that concept blending is the implicit process which governs the creative behavior of icon designers who *create* new icons by blending existing icons and signs. To this end, we propose a simple semiotic system for modeling computer icons. We consider computer icons as combinations of signs (e.g. document, magnifying glass, arrow etc.) that are described in terms of *interpretations*. Interpretations convey *actions-in-the-world* or *concepts* and are associated with shapes. Signs are related by sign-patterns modeled as qualitative spatial relations such as *above*, *behind*, etc. Since sign-patterns are used to combine signs, and each sign can have multiple interpretations, a sign-pattern used to generate a computer icon can convey multiple intended meanings to the icon. These are subjective interpretations of designers when they have to decide what is the best interpretation an icon can have in the real world. In this paper, we show how the intended meaning of new designed (blended) icons can be evaluated and refined by means of Lakatosian reasoning.

## Background

### Computational argumentation

Computational argumentation in AI aims at modeling the constitutive elements of argumentation, that are i) arguments, ii) attack relations modeling conflicts, and iii) acceptibility semantics for selecting valid arguments (Bench-Capon and Dunne, 2007; Rahwan and Simari, 2009).

The most well-known computational argumentation framework is due to Dung (1995). Dung defines an abstract framework to represent arguments and binary attack relations, modeling conflicts, by means of a graph. He defines different acceptibility semantics to decide which arguments are valid and, consequently, how conflicts can be resolved (Figure 2).

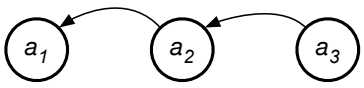

Figure 2: Dung framework example: Nodes represent arguments and edges (binary) attack relations. Argument $a_1$ is attacked by $a_2$ which is attacked by $a_3$. Thus, $a_2$ is defeated and $a_1$ can be accepted. $a_3$ is also accepted.

Abstract argumentation frameworks do not deal with how arguments are generated and exchanged. They merely focus on attack relations between arguments and acceptibility semantics. However, the intrinsic dialectical nature of argumentation is fully explored when an explicit argumentation process is considered. Then, the purpose of a dialogue becomes essential to determine how arguments should be generated and exchanged, and how a dialogue should be structured (Walton and Krabbe, 1995).

### Lakatosian argument and dialogue

Lakatos (1976) was a philosopher of mathematics who developed a model of argument, presented as a dialogue, to

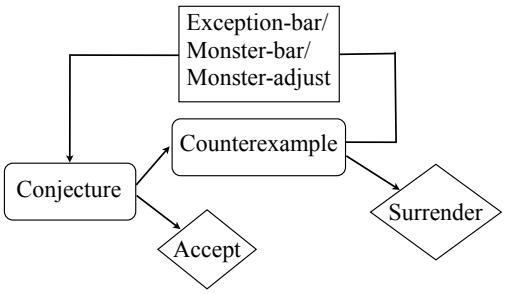

Figure 3: Our interpretation of Lakatos's game patterns.

describe ways in which mathematicians explore and develop new areas of mathematics. In particular, he looked at the role that conflict plays in such explorations, presenting a rational reconstruction of a dialogue in which claims are made and counterexamples are presented and responded to in various different ways. His resulting model describes conceptual continuity and change in the growth of knowledge, and contains dialogue moves, or methods, which suggest ways in which concepts, conjectures and proofs are fluid and open to negotiation, and gradually evolve via an organic process of interaction and argument between mathematicians. These dialogue moves are:

**Surrender** consists of abandoning a conjecture in the light of a counterexample.

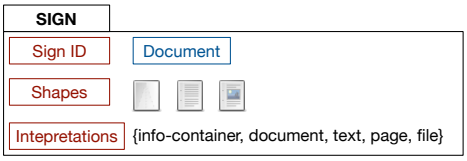
**Piecemeal exclusion** is an exception-barring method that deals with exceptions by excluding a class of counterexamples, i.e., by generalising from a counterexample to a class of counterexamples which have certain properties.

**Strategic withdrawal** is an exception-barring method that uses positive examples of a conjecture and generalises from these to a class of object, and then limits the domain of the conjecture to this class.

**Monster-barring/monster-adjusting** is a way of excluding an unwanted counterexample. This method starts with the argument that a 'counterexample' can be ignored because it is *not* a counterexample, as it is not within the claimed concept definition. Rather, the object is seen as a monster which should not be allowed to disrupt a harmonious conjecture. Using this method, the original conjecture is unchanged, but the meaning of the terms in it may change. Monster-adjusting is similar, in that one reinterprets an object in such a way that it is no longer a counterexample, although in this case the object is still seen as belonging to the domain of the conjecture.

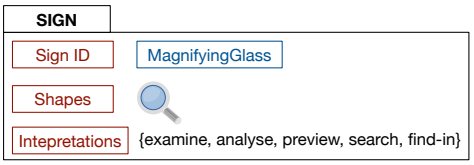
The moves above are not independent processes; much of Lakatos's work stressed the interdependence of creation and justification. These moves describe the evolution of both arguments and conclusions in mathematics, and as such constitute argument patterns, or schemes. However, they are a rational representation of exchanges between mathematicians and describe dynamic, rather than static arguments, presented as a dialogue. Thus, they also have temporal structure, and can be seen as a dialogue game, in which at any point various dialogue moves are applicable (see (Pease et al., 2014) for a description of Lakatos's methods in these terms). The fact that we include negotiations over definitions and changes in the conclusions being argued means that it is difficult to apply traditional abstract argumentation frameworks, which assume that such aspects are stable. However, we can see some of the moves in terms of Dung's framework: for instance if an initial argument for a conjecture forms $a_1$ in Figure 2, then $a_2$ might be a counterexample to the conjecture, and $a_3$ might be the monster-barring move.

The Lakatosian way of conceiving the reasoning as an open-ended discussion about a problem suggests that we can exploit Lakatos's moves for structuring dialogues for the evaluation of creative artefacts. Evaluation in creativity is not a static and rigid process, and the discussion should flow in a dynamic way. As such, in this paper, we propose to use Lakatosian reasoning to model the negotiation about the intended meaning of generated blends (icons). Figure 3 shows the dialogue game we will adopt to model these dialogues. For another formal framework of dialogue games for argumentation see (Prakken, 2005).



## Icons and Signs

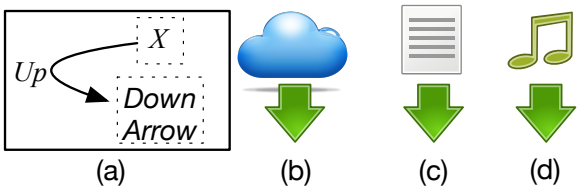
We follow a semiotic approach to specify the intended meaning of computer icons. Semiotics is a transdisciplinary approach that studies meaning-making with signs and symbols (Chandler, 2004). Although it is clearly related to linguistics, semiotics also studies other forms of non-linguistic sign systems and how they may convey meaning; this includes not only designation, but also analogy, and metaphor. Although some people may regard Peirce's Sign Theory as the origin of semiotics, Saussure founded his semiotics (semiology) in the social sciences. Currently, cognitive semiotics and computational semiotics take their own perspectives on the relation between sign and meaning-making. In this paper, we take a semiotic approach to describe computer icons in the sense that icons, as a spatial pattern of shapes, are viewed as signs, and compositions of signs are interpreted to convey a meaning, as when we say 'this icon means the download is still active'.



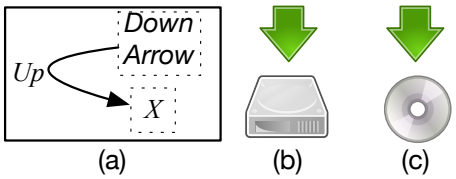
The shapes recurrently used in icons are interpreted as *signs*; screens, magnifying glasses and folders are examples of signs. A magnifying glass sign can be used in different icons in such a way that its meaning is *context-dependent*, that is, it depends on other signs related to it in different icons. We associate to each sign a set of *interpretations*, that encode the kinds of intended meaning associated to that sign as *actions-in-the-world* or *concepts*.

An icon is represented as a pattern defined by a collection of signs and qualitative spatial relations like *above*, *behind*, etc. We can find patterns of meaning that are shared among different icons by analysing recurrent patterns of signs and their spatial relation. We call them *sign patterns*. A sign pattern has an associated collection of *interpretations* that encode the intended meanings associated to that sign pattern.

Signs, sign patterns, and interpretations, which we will use in the paper, can be built by analysing and annotating existing libraries of computer icons. As we shall see, the inherent polysemy of signs, sign patterns and icons opens the way to use arguments for evaluating the quality or adequacy of new icons created by concept blending.



(I) The structure of the DOCUMENT sign, including associated shapes and interpretations.



(II) The structure of the MAGNIFYINGGLASS sign, including associated shapes and interpretations.

Figure 4: Example of signs

(I) (a) the sign pattern FROM-DOWNARROW with three examples of the pattern where X is a sign for (b) cloud content, (c) document content, and (d) audio content.

(II) (a) the sign pattern DOWNARROW-TOWARD with two examples of the pattern where X is a sign for (b) a hard disk storage, and (c) an optical disk storage.

Figure 5: Example of different sign patterns used with the same sign DOWNARROW

## A semiotic system for icons

In this section, we will formalise the notions presented above. A *sign* $S$ is a tuple $\langle id, \mathcal{F}, \mathcal{A} \rangle$ where $id$ is a sign identifier, $\mathcal{F}$ is a set of shapes embodying the sign $S$ and $\mathcal{A}$ is a set of interpretations. We use $\mathcal{S}$ to denote the available set of signs. Figure 4 provides two examples. Figure 4I shows the structure of the DOCUMENT sign, with several shapes embodying the sign, and a list of interpretations that express how this sign is used in different ways to convey meanings such as *info-container, document, text, page, file*. Intuitively, this means that the shapes used in the icons are sometimes interpreted as a document and other times as a page, etc. Moreover, the specific shapes can be used interchangeably to embody a DOCUMENT, i.e. there is no clear distinction, regarding the shapes, between document vs. page vs. file. Another example of a sign is the MAGNIFYINGGLASS shown in Figure 4II, with interpretations *examine, analyse, preview, search*, and *find-in*.

We will also describe a library of annotated *icons* $\mathcal{I}$, where each icon $I \in \mathcal{I}$ consists of two parts: (1) a spatial configuration of signs and (2) the intended meaning of that icon. For instance, in Figure 5I, the icon (b) has the spatial configuration of a 'cloud on top of a downward-arrow' and its meaning is 'downloading content from the cloud'.

## Sign patterns

In our framework, sign patterns relate signs in icons using spatial qualitative relationships such as *above*, *behind*, *up*, *down*, *left*, etc. We assume that these relationships are represented as binary predicates, *Above*(X,Y), *Up*(X,Y), etc., where X and Y are variables ranging over signs in $\mathcal{S}$. For our current purposes, we use the qualitative spatial relationships defined in (Falomir et al., 2012).

Let us consider two examples of sign patterns that include the DOWNARROW sign. DOWNARROW has a vertical downward-pointing arrow shape and is associated with the interpretations {*down*, *downward*, *downloading*, *download-from* and *download-to*}. The sign pattern called FROM-DOWNARROW (shown in the schema labelled (a) in Figure 5I) uses the qualitative spatial relationship *up* between a variable X and the sign DOWNARROW. Examples (b), (c) and (d) in Figure 5I illustrate the intuitive meaning of the sign pattern FROM-DOWNARROW: 'downloading X'. Thus, example (b) refers to downloading cloud content, (c) document content, and (d) audio content.

The inherent asymmetry of arrows in general, and arrow signs particularly, can be appreciated when considering the opposite spatial relation, when the sign DOWNARROW is "up" from another sign (Figure 5II). Then, the sign pattern DOWNARROW-TOWARD is used to mean that X is the destination of the downloading. Example icons (b) and (c) are intended to mean that the data being downloaded (whose type or origin is now elided) is to be stored in a destination such as a hard disk or an optical disk.

## Evaluating Blends using Argumentation

As briefly described previously, the amalgam-based computation of concept blending amounts to combine different input spaces into a new space, called blend, by taking the commonalities of the inputs into account, by generalising some of their specifics and by projecting other elements. In the following, we describe how concept blending can account for modeling the creative process of a designer of computer icons.

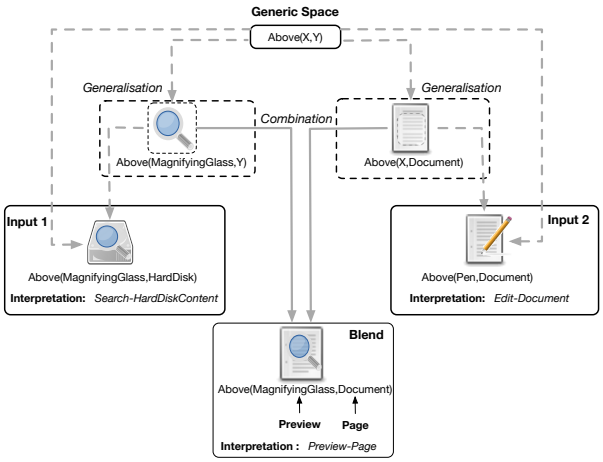


Figure 6: Generating an icon interpreted as *Preview-Page* through amalgam-based concept blending.

## A design scenario

Assume a designer is looking for creating a new icon with the intended meaning of previewing a document or a page. The creation of such icon can be achieved by the following amalgam-based concept blending process (Figure 6). In addition to the DOCUMENT and MAGNIFYINGGLASS signs, we assume we have available a HARDDISK sign and a PEN sign which have already been used to make icons.

**The input mental spaces.** The input mental spaces of the designer are an icon of a hard-disk with a magnifying glass hovering above it, whose meaning is *Search-HardDiskContent*, and an icon of a document with a pen above it, whose meaning is *Edit-Document*.

**The generic space.** The sign pattern *Above*(X,Y) is used in both icons. The first icon contains the relation *Above*(MAGNIFYINGGLASS, HARDDISK) between the MAGNIFYINGGLASS and the HARDDISK, and the second contains the relation *Above* (PEN,DOCUMENT) between the PEN and the DOCUMENT.

**Further generalisation.** Two generalisation steps are needed: *Above*(MAGNIFYINGGLASS,HARDDISK) $\rightarrow$ *Above(*MAGNIFYINGGLASS,Y*)*; correspondingly, *Above*(PEN,DOCUMENT) $\rightarrow$ *Above*(X,DOCUMENT).

**Combination via variable substitution.** We combine the schemas *Above*(MAGNIFYINGGLASS, Y) and *Above*(X, DOCUMENT) via [X/MAGNIFYINGGLASS, Y/DOCUMENT]. The icon of a page with a magnifying glass hovering above it is generated.

**The intended meaning.** The designer associates to the icon the intended meaning of *Preview-Page*, by selecting the interpretations (*Preview*, *Page*) for the MAGNIFYINGGLASS and DOCUMENT signs.

In this case, the designer decided that the intended meaning of *Above*(MAGNIFYINGGLASS, DOCUMENT) is *Preview-Page*, that is, a page can be examined without opening it. However, during the creative process, the designer could have generated other blends, not only by combining other signs, but also by selecting different interpretations associated to the MAGNIFYINGGLASS and DOCUMENT signs. For instance, the icon in Figure 7 still represents a page with a magnifying glass hovering above it, but it has been given a different intended meaning.

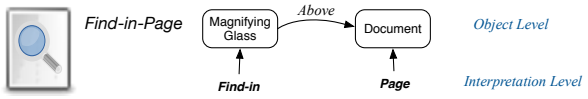

Figure 7: An example of interpreting the sign pattern of an icon as *Find-in-Page*.

The meaning of a blended icon cannot simply be considered right or wrong: interpretation depends on different points of view. Thus the evaluation of whether it is useful or valid for a specific purpose can be the object of a discussion.

## Arguments about intended meanings

In the icon domain, arguments may include a clear interpretation of any constituent signs in the icon if it is a composition of signs, or a good fit with other icons in the icon set.

For example, we can consider a counter-argument, i.e. an argument that *attacks* the interpretation $a_1$ "magnifying glass above document means *Preview-Page*" in Figure 6, to be phrased as follows:

$a_2$ : "However, the icon in Figure 6 can also be interpreted to mean *Find-in-Page*."

The rationale is that the MAGNIFYINGGLASS sign can often be understood as *finding* or *searching* for something. Thus, the icon can be also interpreted as *Find-in-Page* by associating the interpretation *find-in* instead of *preview* for the same sign MAGNIFYINGGLASS (Figure 7).

This attacking argument can be made at an abstract/conceptual level, for instance, by taking other possible blends of the DOCUMENT and MAGNIFYINGGLASS signs related by the sign pattern *Above*(X,Y) into account. Or, alternatively, if there is an icon library that contains an icon that 'satisfies' the argument above, then this attacking argument can be supported by a specific counterexample. Any of these two forms of attack evaluates negatively the icon in Figure 6. Therefore, if there are several alternative designs for a new icon, this attacking argument diminishes the degree of optimality/adequacy of that design with respect to alternative designs.

The original interpretation can be defended, as usually done in computational argumentation models, by a new argument that attacks the attacking argument $a_2$. For instance, the designer may say:

$a_3$ : "The icon in Figure 6 can only be interpreted differently if MAGNIFYINGGLASS is understood to mean *find-in* instead of *preview*. However, the other icons in

my library use MAGNIFYINGGLASS to mean *preview*, not *find-in*."

Argumentation semantics can then be used, once a network of arguments is built, to determine the outcome. For instance whether argument $a_1$, the original interpretation, is defeated or not can be determined as follows (Figure 2): in this example $a_3$ has no attack, so it is undefeated, which means it defeats $a_2$; since $a_2$ is defeated, the attack against $a_1$ is invalid and $a_1$ is undefeated (i.e. is accepted).

Arguments about the intended meanings of an icon can be embedded in a dialogue modeled in terms of Lakatos's moves and the dialogue pattern shown in Figure 3.

## Lakatosian reasoning for blend evaluation

Here we present a Lakatos-style dialogue between two players, a proponent $P$ and an opponent $O$. The goal of each player is to persuade the other player of a point of view, in this paper, the intended meaning of a new blended icon. In such a setting, we expect to see negotiations over the meaning of an icon take place between experts and novices, or between people designing icons and people using (interpreting) them, or various combinations.

To discuss a given icon using Lakatosian reasoning, we assume that an initial conjecture is about the interpretation of an icon usually being an *action-in-the-world* or a *concept*, together with an example of a particular icon and a particular interpretation. The conjecture could be constructed by inductive generalisation.

**Example 1.** In this example, Lakatosian reasoning is used for discussing the intended meaning of a new icon generated by concept blending:

**$P_1$:** "An icon with a magnifying glass over a page means *Preview-Page*" (Conjecture)
**$O_1$:** "I disagree, this icon (Figure 7) means *Find-in-page*." (Counterexample)
**$P_2$:** "No, this is a different case because the magnifying glass must be over pages with text on them to magnify (it shows what we're about to magnify)." (Monster-barring)

After this dialogue, it is agreed that the intended meaning of the icon is *Preview-Page* and the icon itself has been clarified. Alternatively, the proponent and the opponent could make a different evaluation by following different moves. For instance, if the proponent accepts the counterexample, then the intended meaning of the icon can be refined due to piecemeal exclusion:

**$P_1$:** "An icon with a magnifying glass over a page mean *Preview-Page*" (Conjecture)
**$O_1$:** "I disagree, this icon (Figure 7) means *Find-in-page*." (Counterexample)
**$P_3$:** "Ok, only icons with a magnifying glass over a page with text mean *Preview-Page*". (Piecemeal exclusion)

After this dialogue the intended meaning about the new icon has been changed by modifying the conjecture and taking the counterexample into account.

Sometimes players have different points of view due to the sign patterns they have used in their concept blending.

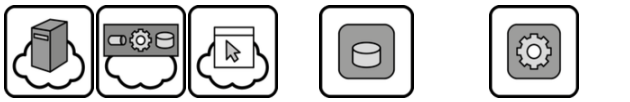

Figure 8: Interpreting the design of cloud icons[2]

**Example 2.** Let us imagine that the proponent has generated an intended meaning for an icon using the FROM-DOWNARROW sign pattern, whereas the opponent has used the DOWNARROW-TOWARD pattern (Figure 5 illustrates these cases). The two players can engage in the following dialogue:

**$P_1$:** "Look at icons in Figure 5I, icons with a DOWNARROW relate to content." (Initial Conjecture)
**$O_1$:** "The icon in Figure 5IIb has a DOWNARROW but doesn't relate to content." (Counterexample)
**$O_2$:** "The icon in Figure 5IIc also has a DOWNARROW but doesn't relate to content." (Counterexample)
**$P_2$:** "The conjecture is right because the two examples actually do relate to content as they are to do with storage and content is part of storage." (Monster-adjusting)

In this case, the proponent excludes the counterexamples using monster-adjusting, and reinterpreting them in a way that they are not counterexamples anymore.

A conjecture might even be at a higher level, for asserting that a particular metaphor is appropriate or inappropriate.

**Example 3.** For example, someone who is familiar with the 'gear means adjust setting' metaphor in one program may be comfortable with it in another program:

**$P_1$:** " An icon containing the 'gear' sign is a good one for Settings, because it invokes the idea of a gear change on a bicycle" (Initial Conjecture)
**$O_1$:** "The 'gear' sign does not invoke the idea of a gear change on a bicycle *from my point of view*." (Counterexample)
**$P_2$:** "Ok, you're right, it does not invoke the idea of a gear change on a bicycle, but it is often used for Settings." (Monster-adjusting)

**Example 4.** Argumentation may also consider the role a given abstract design plays within a given icon set.

**$P_1$:** "Even without knowing what the first or third icon in Figure 8I stands for, I can make a conjecture that it has to do with a server or a user interface accessed via the cloud. However, with the second icon, I'm not sure what it means. It is composed of various signs that I don't understand. It's probably badly designed." (Conjecture)
**$O_1$:** "Did you notice that icons in Figure 8II and Figure 8III are both defined as part of the same icon set? They mean 'Stateful component' and 'Processing component' respectively. Therefore, the second icon is actually well designed, because it uses signs appearing in other icons of the same icon set." (Counterexample)

[2]From `http://cloudcomputingpatterns.org`.

**$P_2$:** "But the second icon contains a pipe sign that is not used anywhere within the icon set, so I still don't know what the second icon means. If there were an icon with a pipe sign with a clear meaning, then I could understand the second icon better. " (Strategic withdrawal)

The main characteristic of employing Lakatosian reasoning is that it allows a dynamic and social development of the intended meaning of blended icons. This cannot be achieved by using only abstract argumentation frameworks, since they assume that the object of discussion does not evolve. Therefore, having an argumentation process of this kind has several advantages: it promotes not only open-discussions around the meaning of an icon, but also the construction of a discourse about how an intended meaning is obtained.

This is a desirable characteristic in computational creativity when evaluating creative outcomes such as concept blends. In this way, the evaluation evolves into a refinement process of an initial created concept, giving much more flexibility at the moment of deciding whether a blend is suitable.

## Discussion

We have illustrated the use of argumentation to evaluate completed blends. We alluded earlier to the role argumentation can play in the *generation* of blends, for instance by suggesting different ways to generalise the input spaces. Indeed, successive statements may serve to carry out the steps in the blending process iteratively, relaxing or refining as needed. These steps can be modelled using Lakatos's moves. From a conjectural candidate solution, to additional criteria that reveal this blend to be a 'monster' (i.e. which identify features of the candidate solution that cannot be allowed in the final solution for one reason or another), to adjustments that yield a more complete description of the problem and point the way toward a more satisfactory solution. An example of using argumentation for deciding which generalisations to use for creating a new icon is the following:

**A:** "We can create a different blend icon starting from the same icons of before." (see Figure 6)

**B:** "We could use the HARDDISK sign from the first icon and the DOCUMENT sign from the second icon."

**A:** "But putting the DOCUMENT sign above the HARDDISK does not make sense from my point of view."

**B:** "You're right, let's use the HARDDISK sign from the first icon and the PEN sign from the second icon."

**A:** "Sounds good, now we have a *Write-HardDisk* icon."

From this discussion and the previous sections, we think that it is feasible to bring the framework of argumentation inside the concept blending process. Moreover, this appears to work in a symmetric direction: the steps in an argumentation process can be carried out through blending. For instance, concept blending could be seen as the process behind the creation of rational arguments (Coulson and Pascual, 2006).

One area closely akin to the icon domain is the domain of *sentences* in a natural or artificial language. These can be evaluated for their coherence, succinctness, and fitness-to-purpose from a semantic standpoint (including relationship to other sentences), among other criteria; cf. (Abramsky and Sadrzadeh, 2014) for a category-theoretic view.

Since people have different standards for evaluation, they frequently disagree about what constitutes a satisfactory result, be it a final outcome or a design decision that is only a step the way to developing an artefact. They may also disagree at a more fundamental level about what can be considered a valid point of view or an appropriate manner of conducting an argument. For example, "Godwin's law" states that an online discussion ends when someone compares one of the discussants to Hitler and whoever made the comparison automatically loses the debate. Naturally, the validity of this principle is itself debatable. During the course of argumentation, the goalposts may shift, as new information is revealed about the domain under discussion, and about the discussants themselves. The relationship between argumentation and decision-making has been explored (Ouerdane, 2009), including the case of updating models of preferences (Ouerdane et al., 2014); the latter is quite similar to our previous work on Lakatos's games (Pease et al., 2014).

## Conclusion and Future Work

Computational models of combinatorial creativity faces the daunting issue of evaluating a large number of possible novel combinations. Particularly, Fauconnier and Turner (1998) propose a model that includes a collection of optimality principles to guide the construction of a 'well-formed integration network'. Our computational model, based on generalisations of input spaces and amalgams, makes this combinatorial nature more explicit. The heuristic criteria called 'optimality principles' are too underspecified to be used as computational measures to evaluate and select possible blends. Moreover, alternative numeric measures may be not enough to evaluate the quality or novelty of creative artefacts. Our intuition is that in the context of creative outcomes, people use argumentation to understand, criticise, modify and evaluate them, and that computational argumentation is a useful tool for computational creativity.

The domain of computer icons generated by blending, where the evaluation of new icons is focused on their intended meaning, shows that symbolic argumentation is a process that is adequate to distinguish well-formed icons from mix-and-match combinations, unambiguous and clear icons from ambiguous or incomprehensible icons. This domain supports our claim that numeric heuristic evaluation measures are insufficient to recognise good blends, and shows the usefulness of an argumentation-based process for identifying good blends, detecting their critical problems, and refining them in an evolving, open-ended process.

We have shown how Lakatosian reasoning can be used in evaluating concept blending for icon design. Our approach offers two main advantages. Firstly, the evaluation process can *improve* the blend, since the dialogue about it refines resulting blends. Secondly, the *reasons behind* a particular evaluation are made explicit. This is crucial given recent work on the importance of context in creativity judgments (Charnley, Pease, and Colton, 2012; Colton, Pease, and Charnley, 2011). Argumentation offers a framing story that

shows how and why a particular artefact was constructed, which can be presented alongside the artefact itself.

We envision several future works. First, we intend to specify an ontology for modelling the semiotic system presented and to build a library of icons. Having a domain knowledge will allow us to generate arguments by induction, for instance, by analysing icons cases. Moreover, it will also open the possibility to explore the use of value-based argumentation (Bench-Capon, Doutre, and Dunne, 2002) for selecting the input icons to be used in the concept blending process. This latter point is important, since usually the inputs of a blending process are assumed to be already provided. Second, as far as the interpretation of icons is concerned, we are thinking to take advantage of existing approaches to natural language processing and understanding, especially Construction Grammars (CxG). In CxG, the grammatical construction is a pairing of form and content. In our semiotic system, sign patterns seem equivalent to the form, while interpretations would be akin to the content. Working with a grammar would make evaluation more explicit, e.g. we could use quantitative measures of ambiguity; and this would open many other domains for application.

Finally, we plan to implement Lakatosian reasoning by employing existing computational tools for argumentation (Devereux and Reed, 2010; Wells and Reed, 2012). Our goal is to provide a computational argumentation framework and to integrate it into the framework for computational creativity we are developing in the COINVENT project.

# Computational Poetry Workshop: Making Sense of Work in Progress

**J. Corneli**[*] Goldsmiths College
**A. Jordanous** University of Kent
**R. Shepperd** Goldsmiths College
**M. T. Llano** Goldsmiths College
**J. Misztal** Jagiellonian University
**S. Colton** Goldsmiths College

**Abstract**

Creativity cannot exist in a vacuum; it develops through feedback, learning, reflection and social interaction with others. However, this perspective has been relatively under-investigated in computational creativity research, which typically examines systems that operate individually. We develop a thought experiment showing how structured dialogues can help develop the creative aspects of computer poetry. Centrally in this approach, we ask questions of a poem, inviting it to tell us in what way it may be considered a "creative making."

**Keywords**: computer poetry, social creativity, flowcharts, Writer's Workshops

'We *can* talk,' said the Tiger-lily: 'when there's anybody worth talking to.'

Through the Looking Glass, Lewis Carroll

## Introduction

We are writing in a large part to champion Alan Turing's proposal that intelligent machines should "be able to converse with each other to sharpen their wits" (Turing, 1951). The formalism that we propose builds on the notion of social cybernetics that flows from the following propositions of Heinz von Foerster's, which he uses to theorise systems in which participants can responsibly specify their own roles in relationship to other system participants:

"Anything said is said *by* an observer."
"Anything said is said *to* an observer."

(Von Foerster, 2003 [1979])

According to Jaako Seikkula and Tom Arnkil, who draw on the philosophical and literary analysis of Mikhail Bakhtin (Bakhtin, 2010 [1986], 1984 [1963]) in their approach to psychosocial work,

"Dialogues could be called 'the art of crossing boundaries'. Instead of trying to control others, the parties reach out towards each other to hear their views better, to generate shared languages and to join resources."

(Seikkula and Arnkil, 2014, p. 23)

This paper outlines a study of social creativity with a dialogical emphasis, taking computer poetry as our working domain. It uses the Writer's Workshop model (Gabriel, 2002) as the virtual laboratory in which to conduct a thought experiment. The findings of our study are applied to the FloWr system (Charnley, Colton, and Llano, 2014). We focus on the following questions in turn:

- How has the social dimension of creativity been explored in CC to date?
- How can a created artefact tell us about its making, and what can this contribute to CC?
- How can computer poetry contribute to developing a process-based theory of poetics?
- What would have to change about the FloWr system to implement the computational poetry workshop approach?
- What are the pros and cons of the workshop approach?
- What might be the future role of dialogue in CC?

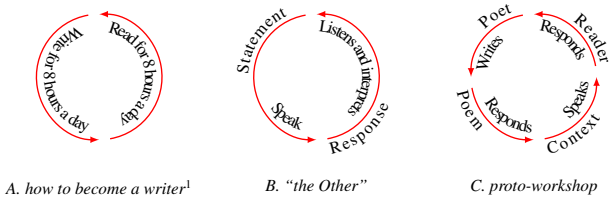
## Background

### Social creativity in CC

Minsky noted that computers need to be social if they are to deal with problems of any great complexity (Minsky, 1967, 1988). We believe that this is particularly true for challenges in computational creativity, since the essence of creativity lives in its appreciation by the creative entity itself and its audience. With creativity in 'the eye of the beholder' (Cardoso, Veale, and Wiggins, 2009), the ability to respond to evaluation during the creative process (Poincaré, 1929 [1908]; Csikszentmihalyi, 1988) becomes pivotal. Social creativity expands this paradigm by introducing co-creators to the process, and creating works that rely on dialogue, reflection, and multiple perspectives (e.g. the stages suggested by (Gervás and Leon, 2014)). 'Results' may be steeped in process and are not always based on consensus.

The Four Ps of creativity – the creative Person, Product, Process and Press (i.e. environment) (Rhodes, 1961) – have been emphasised in general creativity research. *Pluralising* these terms (Persons, Products, Processes) calls further attention to a social dimension of creativity, and would emphasise the way the "Press" accommodates multiple multidirectional perspectives akin to a social network in both the modern and original senses. The Pluralised Ps remind us

that in order to understand creativity it is not sufficient to model a lone creator or to generate an attractive artwork.



To date, computational creativity research has achieved many successes in computational generation of creative products, but the question of how these systems could adapt and learn from feedback to improve their creativity is less-explored in computational creativity (Jordanous, 2015). Evaluation has been advanced as a pivotal contributory part of the creative process, but researchers often give priority to generating artefacts that could be seen as creative over the task of incorporating feedback and evaluation within the processing of a creative system (Jordanous, 2011).

At the previous year's International Conference on Computational Creativity (ICCC 2014) the opening session had the theme "co-creation." However in the main proceedings of the conference, 36 out of 49 papers (approximately 3 in 4 papers) do not appear to mention social interaction or the ability to respond to feedback. Some notable exceptions highlight the usefulness of interaction and feedback for creative systems (McGraw and Hofstadter, 1993; Colton, Bundy, and Walsh, 2000; Sosa, Gero, and Jennings, 2009; Pérez y Pérez, Aguilar, and Negrete, 2010; Pease, Guhe, and Smaill, 2010; Saunders, 2012). Some of this work is influenced by the DIFI (Domain-Individual-Field-Interaction) framework (Csikszentmihalyi, 1988). However, social interaction between creative agents and their audience is often overlooked or relatively simplified: some examples in the domain of computer poetry presented below give the flavour. Increased development of the interactivity of creative systems, especially where this affects the way these systems works, has been highlighted as deserving more attention (Colton and Wiggins, 2012).

FloWr is a framework for implementing creative systems as scripts over processes that can be manipulated visually as flowcharts (Charnley et al., 2014). Its general approach consists of linking the inputs and outputs of code modules, called *ProcessNodes*, together to create a linear flow of data. The resulting Flowcharts can be constructed and executed visually through a GUI; however, they are ultimately represented as scripts, which are the main medium of FloWr. Experiments with automatic process generation in FloWr, reported in (Charnley et al., 2014), highlight the ability of the tool to do meta-programming and modify its own flowcharts. This suggests that FloWr has potential as an environment for modelling social creativity, where the observers are nodes and flowcharts, and their languages are, respectively, programming and meta-programming instructions.

### . . . and in computer poetry

In the domain of poetry-generation, there have already been several attempts to simulate social creativity by incorporating multi-agent systems. In WASP (Gervás, 2010), social behavior is simulated by incorporating a cooperative society of readers/critics/editors/writers consisting of specialized families of experts that cooperate during the poetry-generation process. The McGONAGALL system (Manurung, Ritchie, and Thompson, 2012) incorporates diverse modules as operators in evolutionary algorithms that produce poems fulfilling the constraints on grammar, meaning and poeticity. This approach facilitates the pursuit of several alternative solution paths in parallel, focusing on more promising results or coming back to former ideas. However McGONNAGALL does not provide any communication between modules. In the MASTER system for computer-aided poetry generation (Kirke and Miranda, 2013) a society of agents in various emotional states influences each other's moods with their pieces of poetry. The poetry-generation process is based on social learning as the agents interact by reciting their own pieces of poetry to each other. The generated poems are based on repeated words and sounds, and are closer in some ways to music than to typical language. Montfort, Pérez y Pérez, Harrell, and Campana (2013) and Misztal and Indurkhya (2014) use blackboard approaches to poetry-generation, in which independent specialized modules cooperate via a shared global workspace, *à la* (Baars, 1997). "Experts" exchange information using the blackboard, but without direct communication and without feedback about the reception of their created artifacts.

*A. how to become a writer*[1] *B. "the Other"* *C. proto-workshop*

Figure 1: (A) gives a simple recipe for the growth and development of a writer; (B) *response* always has dimensions that goes beyond the utterance that is overheard; (C) adds a *reader* who shares the context with the writer and responds.

In connection with our work in the current paper, we did a limited proof-of-concept reimplementation of some of the core methods of blackboard poetry system inside of FloWr; we include one of the generated poems and the corresponding flowchart.

## Methods

### "What are the proposed 'lab rats'?"

The generative side of the cycles in Figure 1 has been studied more than the reflective side. Our "lab rats" are, accordingly, not poems per se, but rather, *instances of reading and responding to poetry*. Naturally, such responses could be more or less "canned" (as with Michael Cook's humorously non-specific AppreciationBot[2]), so the question becomes: what constitutes an interesting and useful response, and how will these be developed? The idea of responses is useful at various levels. We focus here on staging an encounter between writer and reader.

### Writer's Workshops

Quoting (Gabriel, 2002, pp. 2–3):

> The original idea behind the writers' workshop was to do a *close reading* of a work... looking at the words on

[1] According to (King, 2000).

[2] https://twitter.com/appreciationbot

> the page rather than the intentions of the author or the historical and aesthetic context of the work. Under this philosophy, the workshop doesn't care much what the author feels about what he or she wrote, only what's on the page.

Framing and any other contextualisation of the work *as it is intended to be presented* is permitted, and receives critical attention. We define a *Workshop* closely following Gabriel's outline, to be an activity consisting of these steps: `presentation`, `listening`, `feedback`, `questions`, and `reflections`. The first and most important feature of `feedback` is for the listener to say what they heard; in other words, what, for them, is in the work. In some settings this is augmented with `suggestions`. After any `questions` from the author, the commentators may make `replies` to offer clarification. In related recent work, we have shown how the Workshop framework can help foster serendipitous discovery and invention (Corneli, Pease, Colton, Jordanous, and Guckelsberger, 2015; Corneli and Jordanous, 2015).

### Content as creative process

Giving agency to the poem rather than the poet's intentions, the poem illuminates its own creative process. This informs our approach to Workshop interactions, which are focusing on the poem observing its own construction. We're interested in context not in the literary or historical sense but in the micro-history of the poem's creative evolution. The originary and therefore unpredetermined nature of the creative process means that the outcome represents a more accurate and objective evidence of the process than the poet's attempt to explain the process. Moreover, to the extent that a creator knows what is expressed through the creative process, even he or she learns this only in the course of doing the work. Observers are only able to consider after the fact how a creator may have selected and rejected various possibilities. The *content* of the poem is no more and no less than how the poem was made.

> "In a poem, objective material becomes the content and the matter of the emotion and not just its evocative occasion." (Dewey, 1958 [1934], p. 69)

P. G. Whitehouse writing on Dewey's *Art as Experience* suggests that Dewey joins Collingwood in separating aesthetic emotion from any notion of inspiration that could be considered to be something like raw materials. An emotion is *aesthetic* when it "adheres to an object formed by an expressive act" (Whitehouse, 1978, pp. 149–156). However, "the art object does not have emotion for its significant content"; rather, the emotion "belongs to the self that is concerned in the movement of events toward an issue that is desired or disliked" (Dewey, 1958 [1934], p. 14).

### Aspects of the creative process

Doug Anderson and Carl Hausman take Collingwood's study further and map the creative process roughly as follows (Anderson and Hausman, 1992, pp. 299-305):

> Disturbance → aesthetic emotion → response → artist's decision on components of expression → feeling of easement plus a simultaneous emerging of a unique imaginative expression → alleviation → realising and converting prior psychical emotion → unique aesthetic experience including new conscious emotion

The poem is a *work of progress* before it is a *work in progress*. The purpose of a poetry workshop that attends to the content of the poem as process is to illuminate what the poet is exploring through his/her creative process and through the poem. The process of reading a poem is also a process of *poiesis* – and in the Workshop, the reader joins the writer in the process of creation. Asking questions like those listed in in Table 1 tells us what the constituent parts of the poem are doing.

### Relevance for CC research

From a CC standpoint, asking what the work tells us about the creative process gives an objective and critical focus on "creative evolution" (Bergson, 1911 [1907]) and provides an antidote to the seductions of mere generation. A poetry workshop gives participants the opportunity to read the drafts and final versions of poems by other Workshop participants, a shared culture of critique that can be applied to previously existing poems, and a structured way to gather feedback on one's own work in progress. These analyses, unbiased by the explanations of the (software) creator, will allow participants to explore and extend the conceptual space around poetry, or in practical terms, the toolbox the agents can access. "Extending" expresses both a refinement of the tools used and the introduction of entirely new tools. Moreover, reverse-engineering of the creative process from artefacts will help to teach agents participating in the workshop at which stage of *their* creative process these new tools or extensions could potentially be used. Dialogue in the workshop involves "respecting the voices of each of the participants" (Seikkula and Arnkil, 2014), be they agents, poems, or individual words – and suggests that we look at the "art of boundary crossing" that is to be found *inside* poems.

## Bridges between 'theory' and 'practice'

Our *ansatz* is that the Workshop could serve as a way to develop a process-based theory of poetics. There are certain prerequisites: in particular, an underlying context is required, shared (with respect to differing points of view) by the poet and the reader/listener (see Figure 1). Participants are assumed to have relatively stable, enduring but evolving, identities – either might be able to ask "Who am *I*?" and "Who are *you*?" (Bakhtin, 1984 [1963], p. 251). Answers would acknowledge a prepared mind with certain prior questions, abilities, involvements, and so on. However, within the Workshop dialogues, the discussion focuses solely on the work itself. Persistent identities allow participants to learn from these exchanges.

Table 1 contains a list of questions that a reasonably sophisticated poetry reader might ask about poems. This is complemented by a list of questions that could be addressed, in a

| Question | Examples |
|---|---|
| What are the register(s) of the poem? | cliched, instructive, imperative |
| Who is addressed? | reader, poet, friend, rival, confidante |
| What position(s) are present in the poem? | pleading, remonstrating, ephemeral |
| What is the poem doing with the reader? | accuse, bewilder, alienate |
| Who are the characters in the poem? | "the falconer", "you", narrator, "two men" |
| What is the role of image(s) in the poem? | "the sea", "a bicycle"; multiple meanings |
| What functions, mechanics, and paradigms are present for the reader to engage with? | communication, subverted cliche |
| What problems, discomforts, or diseasements are invoked in the poem? | horror, self-loathing, rejection, desire |
| How do these evolve? | E.g. an image may start to take over from a register |
| What is the world of the poem, and how does the poem distinguish between this and its perception of this? | "Surely", "must"; sacred vs mundane; perspectival vs surreal; tale vs telling |
| What are the overlaps, transitions, implicit dialogues? | "twinned" lines/ideas, juxtaposed parts of the poem |
| What role does the chronology of reading play, versus references to chronology and chronological positions within the poem? | flagged development, evolution, movement, stasis |
| How are lexical categories used? | solid nouns, tortuous adjectives, indistinct adverbs |
| Are there discernible allusive effects? | illustrating the literary apprenticeship of the author (or reader) |
| Where is the poet presented with respect to the poem? | Confidence, determination, exploration |

Table 1: Questions that we ask when reading a poem

straightforward programmatic manner (Table 2). Each of the examples listed in the right-hand column of Table 1 (and a plethora that are not listed) present a way of thinking about the poem. We can see these as roughly analogous to the agents in Table 2 (Minsky, 2006).

To illustrate, in response to a computer-generated poem:

*Oh dog the mysterious demon*
*Why do you feel startle of attention?*
*Oh demon the lonely encounter*
*ghostly elusive ruler*
*Oh encounter the horrible glimpse*
*helpless introspective consciousness*

A human critic might offer the following feedback:

1. The use of the word *mysterious* in the first line has no resolution, real or attempted, or quest to find one.
2. The use of the word *attention* is not being interrogated or acknowledged for its importance. Its qualifying word is *startle*, used here as an adjective; acknowledging the fact that the attention is noted, but is not yet part of the transformative of the poem.
3. This is repeated in the next references to the aesthetic experience as a *lonely encounter*, *exclusive ruler*, *horrible glimpse* and *introspective consciousness*.
4. The contact made between the poem and its own construction is qualified in negative terms attached to the words *demon*, *encounter* and *consciousness*.
5. This poem does not welcome the intimacy of bringing anything to aesthetic consciousness so that it might be expressed. Why do I say that? Because the words are generalised and *horribly* imprecise.
6. The poem does not move toward a better understanding of the ideas it alludes to. The vocabulary seems to associate exploration with fear and isolation and this is (paradoxically) quite an interesting acknowledgment of the poem's refusal to go anywhere i.e. to become a thing transformed by a creative process.

| Question | Agent concerned |
|---|---|
| ***Word level*** | |
| What is are dictionary definitions of this word? | WordNet expert |
| What are its etymological roots? | Etymology expert |
| Where did this word come from? | Provenance expert |
| What pronouns are used in the poem? | Pronoun expert |
| ***Phrase level*** | |
| What are the components? | Keywords expert |
| Do the components have a negative or positive connotation? | Association expert |
| What are the modifiers attached to the components? | Modifer expert |
| ***Sentence level*** | |
| What is the parse tree? | Grammar expert |
| ***Line level*** | |
| How long is the line? | Counting expert |
| Where does it break? | Breathing expert |
| Where is there white space? | Position expert |
| ***Poem level*** | |
| How are terms that exhibit emotion distributed within the poem? | Distribution expert |
| Where is there alliteration (rhyme, consonance) in the poem? | Phonics expert |
| Does the poem have a metrical structure? | Rhythm expert |
| How repetitive is the poem? | Repetition expert |
| Does the poem cohere? | Thematic expert |
| Does the poem have a progression? | Narrative expert |
| Where are the various elements of the poem concentrated? | Entropy expert |

Table 2: Questions we imagine a computer would currently be capable of answering when reading a poem

Each of these six points is *dual-voiced* in the sense that the critic is relaying the words of the poem with a new emphasis. Each such statement is one side of a micro-dialogue (Bakhtin, 1984 [1963], p. 73). The challenge is, of course, to bring the observations into the awareness of the computer poet, across the "analogue divide." Care should be taken not just to blythely program the computer with more rules, but rather to give attention to facilitating the process of learning new rules contextually. We continue with the example from this point of view in the following section.

First we will consider a reversal of roles, with the computer in the position of critic, looking at a passage from an historical piece of poetry. We have selected a passage from Robert Burns that might have – but in fact did not – serve as a model for the poem generated above.

*I'm truly sorry man's dominion*
*Has broken Nature's social union,*
*An' justifies that ill opinion*
*Which makes thee startle*
*At me, thy poor, earth born companion*
*An' fellow mortal!*

Naturally, the first problem is for the computer to *read* the poem. One of the approaches that is most appealing from our point of view is the automatic generation of a semantic network from the input text (Harrington and Clark, 2007). We could straightforwardly extend the methods of Harrington and Clark with notions drawn from Table 2.

1. The passage begins with *I*/*me*, locating the *poor, earth born* poet
2. *thee*/*thy* is another person, possibly the reader, who becomes *startled*
3. Singular *I* contrasts with the class *man*
4. *sorry* is a sad emotion
5. *truly* exaggerates sorry
6. *dominion* is large
7. *broken* and *union* are opposites
8. *sorry* and *justifies* are opposites
9. *union*, *companion*, and *fellow* are positive words about relationship and joining
10. *broken*, *ill*, *poor*, *startle* and *mortal* are related to frailty
11. *born* and *mortal* are related
12. There are a lot of rhymes in the poem, at the end of the lines, enjambed.

These comments are very different from the other reading above, and are differently interesting.

We've demonstrated that the computer is capable of asking objective questions of a poem. A similar semantic network approach would allow it to listen to feedback and take it on board, even when it doesn't understand the ways of thinking that generate this feedback. Again, this links the process of reading and writing poetry to a process of dialogue.

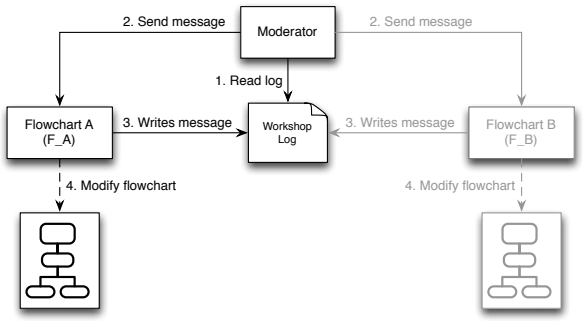


Figure 2: Schematic diagram for a workshop built in the FloWr system

## Seeds for a FloWr Garden

Keeping in mind the current limitations of FloWr – no looping or conditionals, only running one flowchart at a time and in one direction – a *conversation* between ProcessNodes or flowcharts is not immediately feasible. Figure 2 represents a hypothetical design in which a Workshop could take place with a minimally-altered version of FloWr. As shown in Figure 2, each participant in the Workshop would be represented by a single node. One of these nodes is a *moderator* in charge of dictating the interaction between the participants of the Workshop, while the rest represent *flowcharts* that have the ability to modify their own connections according to the discussions from the Workshop – this can be achieved by exploiting the scripting mechanism of FloWr and dynamically loading the new structure of the flowchart. Moreover, a shared *log* would contain the history of the messages exchanged during the Workshop and a queue of messages waiting to be delivered. We define four different types of messages that can be exchanged:

- ***comments*** about specific elements of a poem, or more general statements about how the poem affects this reader.
- ***questions*** to facilitate comprehension of this commentary; for instance, the questions can vary from simple requests of sources of information (e.g. files, input from another node, which resources a flowchart uses, etc.) to process-specific details (e.g. current conditions, purpose, other outstanding questions, etc.)
- ***answers*** would be associated to previous questions and may contain simple text such as an url for the source of information, or a piece of script representing a node used by a flowchart.
- ***suggestions*** are changes proposed by one participant to another. Similar to the answer, this can be as simple as suggesting the change of an information source, or more complex, such as suggesting the replacement of a node for an alternative node.

A Workshop session follows this communication protocol:

1. The moderator initialises an empty log and sends a message to the flowcharts to indicate that the session has started.
2. The flowcharts start writing messages in the log.
3. The moderator checks the current state of the workshop by reading the log.
4. The moderator selects the next message in the queue and passes it to the target flowchart.
5. The flowchart reads the message and acts accordingly, by either (*i*) modifying its connections or; (*ii*) sending a message back, i.e., writing to the log.
6. Step 3 is repeated until no further message are left in the queue.

**Example.** Figure 3 shows the poetry generator flowchart that generates the poem about the "demon dog" presented above. The flowchart uses two linguistic resources: ConceptNet (Liu and Singh, 2004), a semantic network of common knowledge, and Disco (Kolb, 2008), a semantic similarity words retrieval system. Let us assume the human critic **A** has access to the system through a "UI flowchart" like a Read-Eval-Print Loop (REPL), and the poetry generator **B** is mainly concerned with maintaining a generative flowchart like the one shown in the figure. The following exchange of messages can occur:

1. **Comment from participant A to participant B**: *The words "lonely encounter" and "elusive ruler" in lines 2 and 3 are generalised and imprecise.*
2. **Question from participant B to participant A**: *I identify the processes* Disco3 *and* Disco4 *as the source of the problem. Can you suggest an alternative to Disco?*
3. **Suggestions from participant A to participant B**: *Use WordNet or the Historical Thesaurus to find more expressive and specific terms for the core concepts in the poem; try to link the core concepts together by chaining together related concepts in ConceptNet or WordNet.*
4. **Action executed by participant B**: Receives suggestions, creates several alternative versions of the script, executes them and decides which one is most coherent and which conveys a sense of narrative.

From this exchange, the computer might learn (without ever being explicitly told) that expressive terms and narratives are related, and it might begin to discover a way to produce coherent poems with a narrative structure.

Since the computer has source code instead of a brain, we can use it to do control studies with process. However, in general source code does not uniquely determine process: contextual effects are what make an experiment an experiment. As described in (Cook and Colton, 2013), code may include hints about its expected operating context. This is related to our theme of embedding process within an artefact. In this connection, one extension to FloWr that would help to facilitate dialogue between flowcharts would be to add machine-readable *commentary* to ProcessNodes. Commentaries would label a node's inputs and outputs, describe its basic purpose, and provide information about procedure, conditional behaviour, mappings between processes and elements of a generated poem (like the mapping between Disco3 and "lonely encounter").

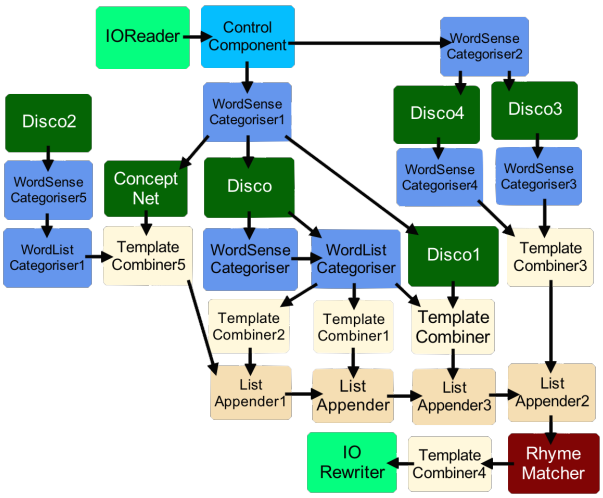

Figure 3: The flowchart that created the "demon dog" poem

Altered versions of a flowchart (Charnley et al., 2014) can be seen as parallel solutions that could be executed and compared on a population basis with respect to some prespecified metrics in order to make an informed decision on which suggestion(s) to follow, as hinted in the last step of the example. In (Colton, Pease, Corneli, Cook, and Llano, 2014) we explored the related idea of modelling system progress over time. Learning new rules contextually would offer one clear measure of progress. Caveat lector: considerable work would be required to realise the ideas we've described in FloWr or any other platform we're aware of.

## Discussion

**Potential applications.** The paradigm advanced in this paper would not remove the "generation" aspects of CC, but would pair them more closely with reflection. The same skills that support learning in a writers workshop may support a form of dialogue with the work itself, leading to richer creative artefacts that show us more about how creativity works. Focusing on social creativity does not suggest that we should devalue works from lone creatives, but it does suggest that we think about how we knit individuals together in the social fabric of the CC community. The current model at the International Conference for Computational Creativity (ICCC) is similar to many other academic conferences: we present *our* work to one another and build *our* sense of community in that way. But what about a track for computers to present their work? The idea of computers interacting in a workshop-like setting is not unprecendented. As Turing (1951) foresaw, computational software has become highly competent at Chess and reasonably competent at Go, partly through continuous practice pitting programs against each

other. Poetry could be approached in a similar way, reviving the *floral games* of the troubadours. Other creative arts may also be amenable to the same sort of approach. Gabriel mentions "brainstorms, critiques, charrettes, pair programming, open-source software projects, and even master classes" (Gabriel, 2002, p. 11). The sort of thinking we have developed here might be adapted to contexts like these.

**Potential criticisms.** It can be challenging and time-consuming to invite and process feedback, and the Workshop would often be seen as unnecessary for standardised production cycles that can already produce artefacts that are "good enough." Furthermore, since we often seem to *get* the computer to do just what we have in mind when we're programming, it might not make sense to treat it as a distinct other and invite it to participate in a dialogue. (Some REPL users may disagree, and may already think of programming as a dialogue.) From our read/write perspective on computational creativity, the most immediate problem is that appreciation of works of art is rather hard. Consider the difference between creating a video game (for example) and playing a video game. In the first case, the designer has full control over the rule-set, game mechanics, interaction devices and so forth. At least one computational video game designer can play its own games (Cook, Colton, Raad, and Gow, 2013), and an experiment shows that it is possible for an artificial game player to learn how to play classic video games using reinforcement learning, starting from raw pixels (Mnih et al., 2013) – but both are quite far from general-purpose game playing. This is itself a topic of contemporary research, and it serves to illustrate that coping with feedback is a major challenge for AI research. Finally, we are not in a position to make strong claims about the quality of workshopped artefacts, although our experience with poetry has shown us that high-quality poems are often exactly the ones which teach us about the creative process. We hope future research will explore this connection further.

## Conclusions

The ideas of social interaction, feedback, and evaluation have frequently been discussed in CC, but implementation and theorisation around these topics have been more limited. In the current paper, we suggest giving artefacts more agency, designing computer programs with more autonomy, and focusing research effort on creative evolution. We have shown that in principle computers can engage in dialogue about poems, which points to a theory of poetics rooted in the making of boundary-crossing objects and processes. In order to move from thought experiment to computational simulation, FloWr could be helpfully extended with further programmer facilities including loops, subroutines, and commentaries, along with the ability to generate-and-test in a population-based manner, and the ability to learn over time. Workshops and related approaches are suitable for autonomous learning and development of the creative process, but they face technical and also some theoretical limitations. Dialogue may offer a way to creatively push these limits, empowering both programs and programmers.

# The Search for Computational Intelligence

**Joseph Corneli** [1] and **Ewen Maclean** [2]

**Abstract.** We define and explore in simulation several rules for the local evolution of generative rules for 1D and 2D cellular automata. Our implementation uses strategies from conceptual blending. We discuss potential applications to modelling social dynamics.

## 1 Introduction

This paper takes a local approach to studying the evolution of cellular automata (CA), following on the global approach of "PICARD" [24].

> *Like a traditional one-dimensional CA, PICARD executions move from one iteration to another by some rule. However, whereas traditional CA's require the rule to be static and externally specified, PICARD infers the iteration rule from the current state of the CA itself.* [24, pp. 1–2]

PICARD's inferred rule is derived from the current state of the CA by a global characteristics, such as the number of 1's in the CA's current state (modulo 256), or the density $\rho$ of 1's (normalised as $\rho/256$). These global criteria are similar to Van Valen's theory of resource density as an "incompressible gel" [29].

In the current paper we introduce the notion of a MetaCA, in which CA rules are derived locally at each cell within the CA as it runs. Examples appear in Figure 1. Here, each colour represents one of the 256 standard one-dimensional CA rules. States evolve locally, according to globally-defined dynamics.

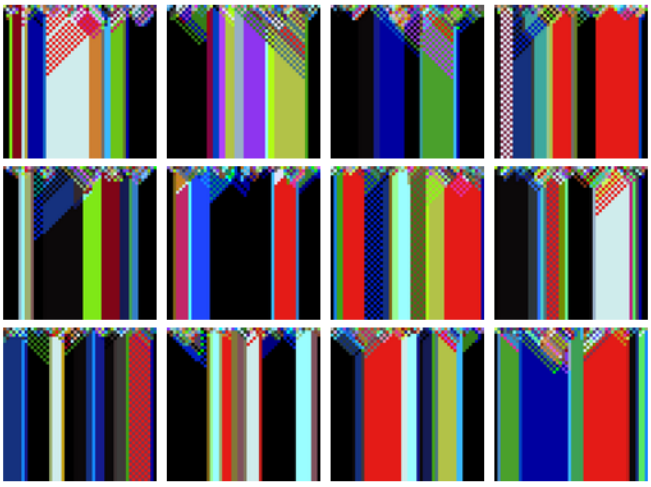

**Figure 1.** An illustration of MetaCA evolution

## 2 Background

### 2.1 Cellular Automata

Each elementary 1D CA rule defines a mapping from all eight triples formed of 0's and 1's to the set $\{0,1\}$. Thus, for example the rule **01010100** is defined as the following operation:

$$\begin{array}{cccc} 0 & 0 & 0 & \mapsto \mathbf{0} \\ 0 & 0 & 1 & \mapsto \mathbf{1} \\ 0 & 1 & 0 & \mapsto \mathbf{0} \\ 0 & 1 & 1 & \mapsto \mathbf{1} \\ 1 & 0 & 0 & \mapsto \mathbf{0} \\ 1 & 0 & 1 & \mapsto \mathbf{1} \\ 1 & 1 & 0 & \mapsto \mathbf{0} \\ 1 & 1 & 1 & \mapsto \mathbf{0} \end{array}$$

The rules determine the next generation of a 1D CA locally, from three "parents". In the example, $\boxed{0}\boxed{0}\boxed{0} \mapsto \boxed{0}$ and $\boxed{0}\boxed{0}\boxed{1} \mapsto \boxed{1}$ and so on. There are 256 of these rule tables; the example above is Rule 84 in Wolfram's standard enumeration [31]. A crucial development in the history of CA research was the proof [5] that certain CA rules are Turing complete (in particular, Rule 110 enjoys this property).

Earlier classic works [14, 17, 23] exploring related "edge of chaos" effects. In [23, 17, 16], genetic algorithms are used to search the space of CA rules via crossover and mutation. This sort of evolution is global and is connected with the CA rule by a derived parameter, "Langton's $\lambda$" (cf. [14]). An overview of the "EvCA" programme is presented in [12]. CAs are also explored in two (and more) dimensions and with irregular topologies [7, 6]; in this paper, we develop both 1D and 2D examples. Closest to the work presented here is [26], which introduces the paradigm of *cellular programming*. As the name indicates, this approach is a fusion of ideas from cellular automata and genetic programming.

> *As opposed to the standard genetic algorithm, where a population of independent problem solutions globally evolves, our approach involves a grid of rules that coevolves locally.* [26, p. 74]

In cellular programming, local evolution of the CA rule makes use of a "fitness" metric ([26, pp. 79–81]), as the systems are evolved to perform certain global computational tasks. In the current effort system evolution is not directly guided by a specific fitness criterion. This paper defers any detailed *post hoc* analysis of MetaCA behaviour, although we hope to explore this further in a sequel, possibly following in the footsteps of the EvCA project [9, 10, 13].

### 2.2 Modelling social dynamics

Previous researchers have looked at CAs "as multi-agent systems based on locality with overlapping interaction structures" [6]. An

early application of cellular programming was to evolutionary game theory, a field with natural parallels (cf. [22]). We are inspired by recent work in this area on the evolution and failures of cooperation [1, 21, 27, 28] but we do not use a game theoretic approach. George Mead extends the term *social* to describe any scenario exhibiting emergent coevolution; this becomes central to our discussion.

> *What is peculiar to intelligence is that it is a change that involves a mutual reorganization, an adjustment in the organism and a reconstitution of the environment; for at its lowest terms any change in the organism carries with it a difference of sensitivity and response and a corresponding difference in the environment. . . . Now what we are accustomed to call social is only a so-called consciousness of such a process, but the process is not identical with the consciousness of it, for that is an awareness of the situation. The social situation must be there if there is to be consciousness of it.* [15, pp. 4, 48]

## 2.3 Conceptual Blending

One of our inspirations for working with cellular automata is that we are involved with a research project that studies computational blending [25], and cellular automata seem to offer a very simple example of blending behaviour. That is, they consider the value of neighbouring cells, and produce a result that "combines" these values (in some suitably abstract sense) in order to produce the next generation. We were also inspired by the idea of "blending" ordered and chaotic behaviour to produce edge-of-chaos effects. We propose to exploit existing formalisms of blending (in the style of Goguen [11]) in the context of cellular automata to investigate emergent and novel behaviours. The fundamental building blocks used in calculating concept or theory blends are:

**Input Concepts** are the concepts or theories which are understood have some degree of commonality (syntactic or semantic).

**Signature Morphism** is a definition of how symbols are mapped between theories or concepts.

**Generic Space** is the space which contains a theory which is common to both input theories.

**Blend** is the space computed by combining both theories. The computation is computed using a "pushout" from the underlying categorical semantics [18].

Once a blend has been computed, it may represent a concept which is in some way inconsistent. Equally it may represent a concept which is in some way incomplete. We can then either weaken an input theory, or refine the blend:

**Weakening** Given an inconsistent blend it is possible to weaken the input concept in order to produce a consistent blend. Weakening means removing symbols or axioms from the input concept.

**Refinement** Given a blend which represents a concept which is in some way incomplete, it is possible to refine the concept by adding symbols or axioms.

In this paper the primary examples have input concepts expressed in the same language, and indeed have the same specification. This means that the morphisms are not interesting and the calculated pushout could be computed without utilising the full machinery of category theory. Planned extensions will explore the idea of combining rules for cellular automata which may have entirely different techniques for expressing propagation (and we provide one example). For this reason, we target the Heterogeneous Tool Set (HETS) system [19] as an infrastructure for computing blends. We describe our current approach to blending in the context of cellular automata in Sections 3.2 and 3.3.

# 3 Implementation

## 3.1 Generating Genotypes

A MetaCA evolves a CA with 256 possible states – rather than the traditional $\boxed{0}$ and $\boxed{1}$ – where each state now corresponds to a "1D CA rule". By positioning three CA rules next to each other, we define a multiplication by applying the central rule bitwise across the alleles. For example, here is the result of "multiplying" $01101110 \times 01010100 \times 01010101$. In the context of such an operation, we refer to the central term as the "local rule." This example uses Rule 84 as the local rule, highlighted in bold.

| | | | | |
|---|---|---|---|---|
| 0 **0** 0 | | 0 | | *Apply local rule to "000"* |
| 1 **1** 1 | | 0 | | *Apply local rule to "111"* |
| 1 **0** 0 | | 0 | | *Apply local rule to "100"* |
| 0 **1** 1 | $\mapsto$ | 1 | | *Apply local rule to "011"* |
| 1 **0** 0 | | 0 | | *Apply local rule to "100"* |
| 1 **1** 1 | | 0 | | *Apply local rule to "111"* |
| 1 **0** 0 | | 0 | | *Apply local rule to "100"* |
| 0 **0** 1 | | 1 | | *Apply local rule to "001"* |

Realised in a simulation with random starting conditions, the results of this operation are not particularly impressive: they stabilise early and do not produce any interesting patterns (Figure 2).

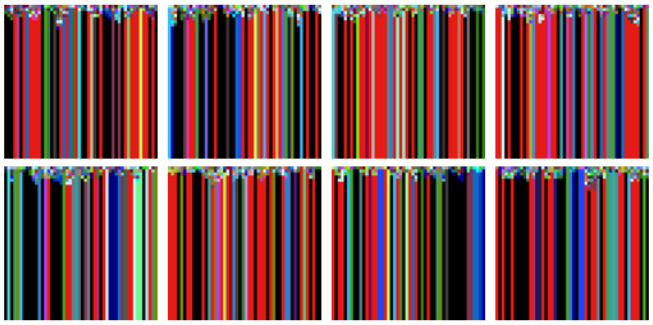

**Figure 2.** Under evolution according to the local rule without blending dynamics, a barcode-like stable pattern forms quickly

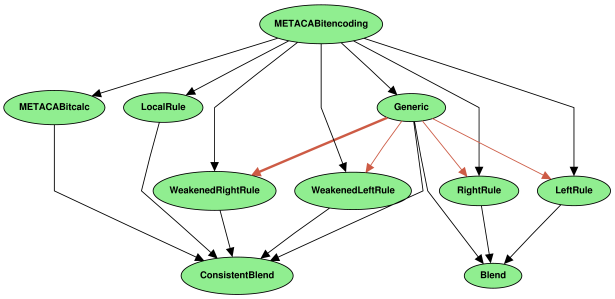
## 3.2 Introducing Blending

The blending variant says to first compute the "generic space" by noting the alleles where the two adjacent neighbours are the same, and where they differ. Only when the generic space retains some ambiguity (indicated by $\{0,1\}$) do we apply the local rule (again recorded on the centre cell at left and highlighted in bold) in a bitwise manner across each allele, to arrive at the final result.

| | | | | | |
|---|---|---|---|---|---|
| 0 **0** 0 | | 0 | | 0 | *Neighbours are both 0* |
| 1 **1** 1 | | 1 | | 1 | *Neighbours are both 1* |
| 1 **0** 0 | | $\{0,1\}$ | | $\boxed{0}$ | *Apply local rule to "100"* |
| 0 **1** 1 | $\mapsto$ | $\{0,1\}$ | $\mapsto$ | $\boxed{1}$ | *Apply local rule to "011"* |
| 1 **0** 0 | | $\{0,1\}$ | | $\boxed{0}$ | *Apply local rule to "100"* |
| 1 **1** 1 | | 1 | | 1 | *Neighbours are both 1* |
| 1 **0** 0 | | $\{0,1\}$ | | $\boxed{0}$ | *Apply local rule to "100"* |
| 0 **0** 1 | | $\{0,1\}$ | | $\boxed{1}$ | *Apply local rule to "001"* |

For illustrative purposes, this blend has been formalised in the HETS system by introducing CASL files to represent the 8 bit encodings (Listing 1, and corresponding development graph shown in Figure 3). In this example, the first computed blend is inconsistent as there is not a unique value representing the output value of each function. In order to resolve this, we weaken the input rules in CASL by removing the function values which cause conflict. Note that purposes of efficiency, we have implemented our 1D experiments in LISP rather than in HETS/CASL. We've put the working code on Github[3].



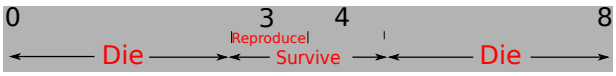


**Figure 3.** The development graph for calculating a blend of 8 bit encodings

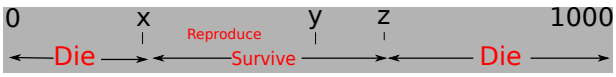
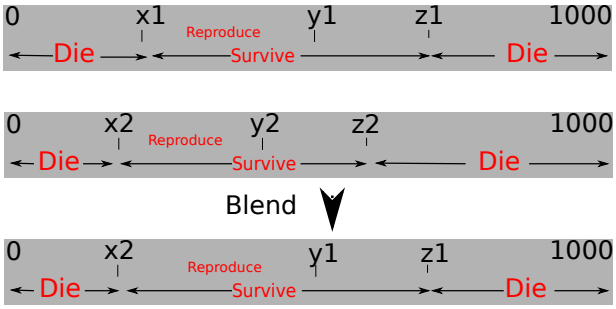
## 3.3 2D Experiments



In order to extend the ideas presented so far in the 1D case, let us consider a variant of Conway's Game of Life [7], in which a global rule exists defining whether a square is alive or dead. We extend this by introducing the notion of a local rule at each square – a genotype, which governs the propagation of the phenotype.

In Conway's Game of life, one can view the rules for propagation as partitions on a finite interval $[0, 8]$.

The number on the line corresponds to the number of alive neighbours adjacent, in cardinal and inter-cardinal directions, to a given square. If the square is dead then it becomes alive (labelled reproduce) if the number of alive neighbours is exactly three. If there are five or more alive neighbours the square dies from overcrowding. If there are fewer than three alive neighbours the square dies from underpopulation. In all other cases the square maintains its status.



This can be generalised to partitions within a more finely grained line, for example from 0 to 1000, one creates a genotype $(x, y, z)$:

We introduce the corresponding notion of a *weight* for each cell. The *phenotype* of the cell is then a pair $(alive, weight)$ which denotes whether the cell is alive, and what weight is has. In this paper we always calculate a newly propagated weight as the average of the neighbours' weights.

[3] https://github.com/holtzermann17/metaca

The notion of local propagation is introduced by allowing the genotypes to be blended at each point where a cell remains or becomes alive. As we have represented the genotype as a partitioned line, we can, for example perform a blend where the partition is blended in such a way as the minimise the lowest bound and maximise the highest bound, and maximise the interval for reproduction. Given two genotypes $(x_1, y_1, z_1)$ and $(x_2, y_2, z_2)$, the blend is $(\min\{x_1, x_2\}, \max\{y_1, y_2\}, \max\{z_1, z_2\})$:

Note that this is just one of several possible blending strategies, which we refer to as a *union* blend, since it maximises the partitions which pertain to survival. We consider alternative blends in our experiments.

# 4 Results

## 4.1 1D CAs

One of the first things we noticed was that even though the blending dynamic creates more interesting "CA-like" patterns than simple evolution according to the local rule (as illustrated in Figure 1), it also forms stable bands after this interesting initial period. In Figure 4, this is illustrated in a CA running with 500 cells over 500 generations. Figure 4 also includes a phenotype (in black and white) which is driven entirely by the genotype: that is, if the local genotype is $\boxed{\alpha}\boxed{\beta}\boxed{\gamma}$ where $\alpha, \beta, \gamma \in \{0, 1\}^8$ and the local phenotype is $\boxed{a}\boxed{b}\boxed{c}$ where $a, b, c \in \{0, 1\}$, then the genotype evolves locally according to the meta-rule $\alpha \times \beta \times \gamma$ (in the blending variant) while the phenotype evolves by applying the local rule $\beta$ to the data "$abc$."

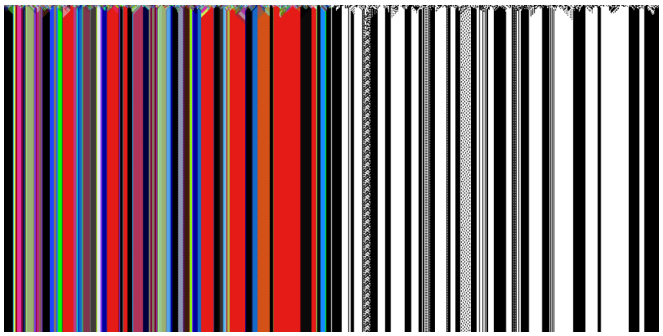


**Figure 4.** Phenotype with behaviour determined by genotype

In the phenotype layer, we see a few bands with interesting patterns, where the MetaCA at left has stabilised locally into one of the more interesting CA rules. However, at this scale we see that the long term evolution in the genotype layer is uninteresting: the structure observed in Figure 1 disappears quickly.

We therefore decided to introduce random mutations to the genotype, illustrated in Figures 5–7. With a high mutation rate, both genotype and phenotype are almost reduced to confetti. If we reduce the mutation rate sufficiently, some degree of stability is preserved, and the vertically striped bands are transformed into intermingling swaths of colour (Figure 6). We also see areas with more finely-grained structure in the phenotype layer.

In Figure 7, the colour-coded genotype layer has been replaced with a greyscale coding, and we see more clearly how the phenotype behaviour follows that of the genotype. That is, genotypes similar to Rule 0 (00000000) or Rule 256 (11111111) tend to produce 0 or 1, respectively, in the phenotype layer. Rules that output a blend of 0's and 1's are mapped to grey shades. Several interesting rules (Rule 110, Rule 30, Rule 90, Rule 184, and their reversals, bitwise inverses, and inverted-reversals) are highlighted in colour. In particular, Rule 110 variants are highlighted in red.

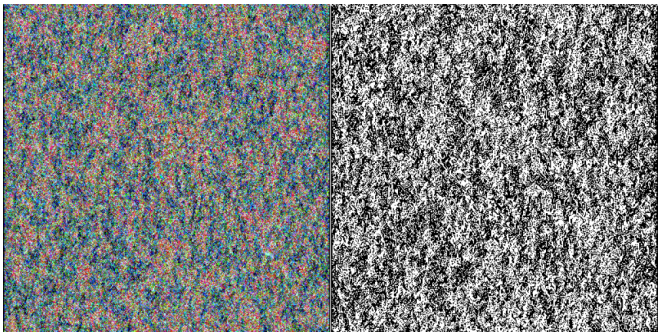

**Figure 5.** A high rate of mutation produces tantalising random structures

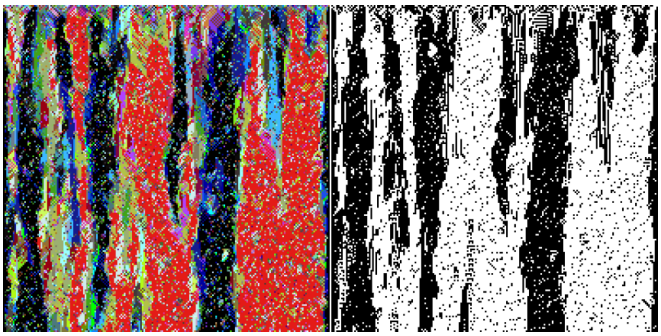

**Figure 6.** Throttling down the mutation rate preserves some of the large-scale stability while making room for variability

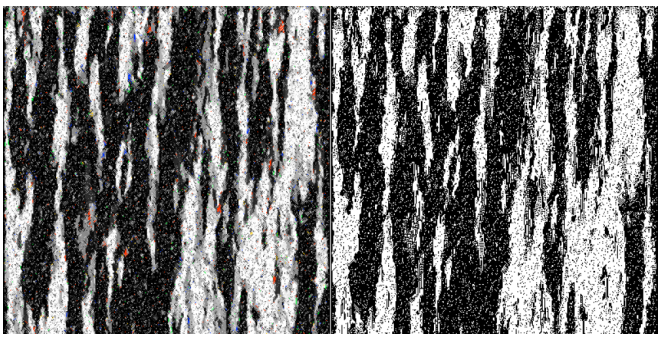

**Figure 7.** The search for intelligent life in the computational universe

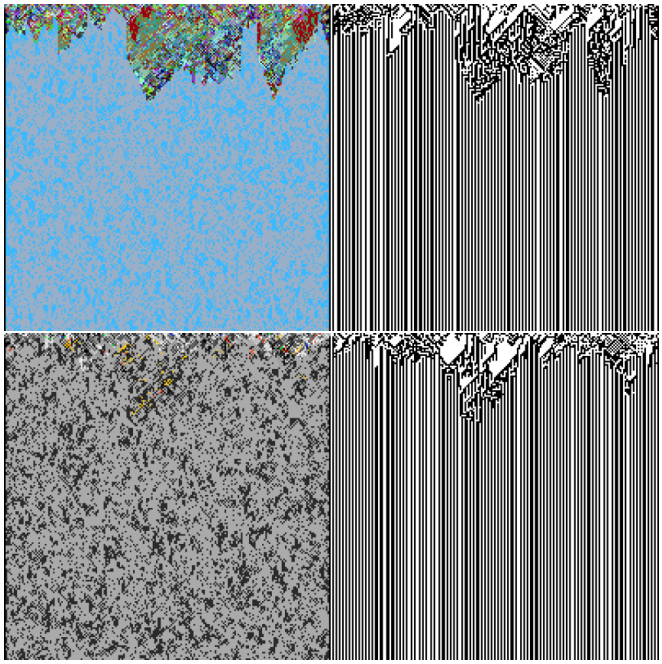
We observe that Rule 0 and Rule 256 behaviour tends to predominate. Grey areas appear to be semi-stable. Red patches appear and disappear, as if independent planets evolve intelligent life and are then extinguished. With this physics, "intelligent life" seems inevitable, but also inevitably short-lived. One would have to look for another overall physics for intelligent behaviour to predominate.

A potential indication of the direction to look in is presented in Figure 8, which presents CAs generated by adjusting the typical blending evolution pattern by an (erroneously-programmed) mutation rule that only flips the first bit. We see that long-term behaviour in the genotype flutters randomly between Rule 0 (00000000) and Rule 128 (10000000). The short-term behaviour in the phenotype is nevertheless quite interesting, exhibiting many of the familiar lifelike edge-of-chaos patterns before ultimately succumbing to a version of Newton's First Law.



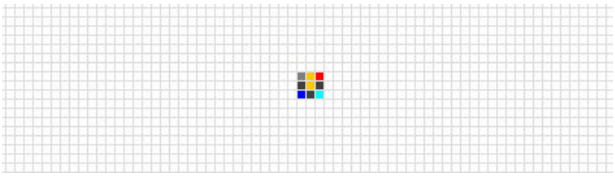


**Figure 8.** A skewed mutation pattern

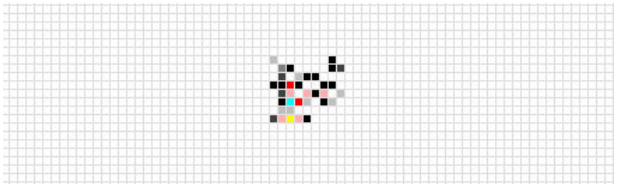
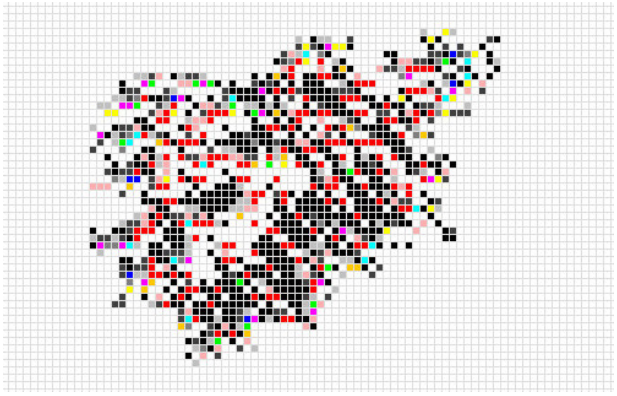
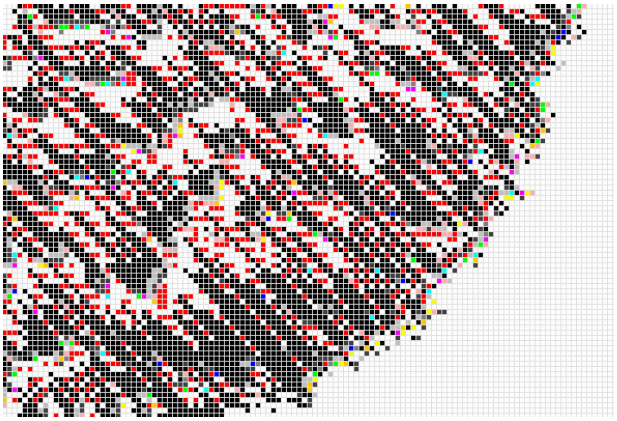


## 4.2 2D CAs

To see the behaviour of the union blend in action consider an initially populated grid, where colours represent the weights of alive cells:



For this example, we initially restrict the computation of the blend for a particular cell to take place when the cell is alive in the next iteration. Also we compute the blend of genotype for all neighbours, whether dead or alive.



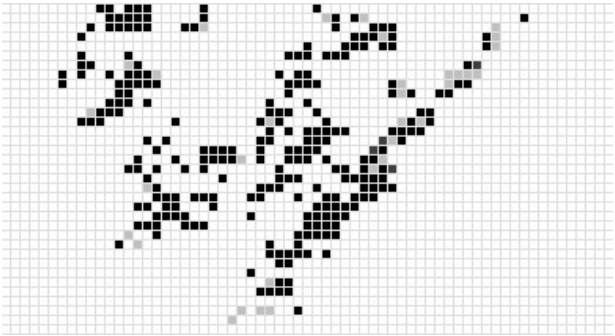
After 300 iterations the colony has grown a small amount:

Over time, the population continues to grow, with large patches of low-weight (black) cells:

Finally some structure starts to appear in the clustering:

The propagation that follows shows a population of cells which grows slowly over time. The majority of the members have low weight (represented by black squares), but interspersed within the population are chains of squares with high weight (represented by red squares) adjacent to dead cells (white).

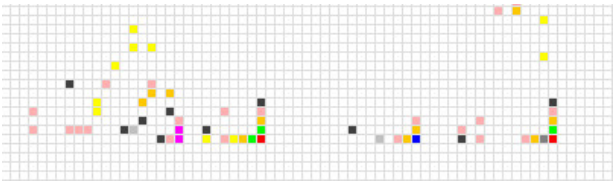
### *4.2.1 Modified Blends*



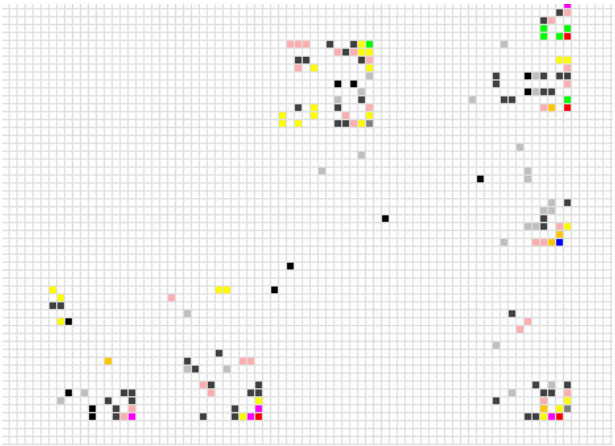
So far we have only showed the union blend working on the genotype. However, it is possible to use different blending techniques:

- Consider blending only the genotypes of alive neighbours, or all neighbours;
- Consider only blending genotypes for cells which are alive after propagation;
- Consider an *intersection* blend, where the partition sizes for survival are minimised;
- Consider an *average* blend, where the values of each genotype $(x_i, y_i, z_i)$ are summed and divided by either the number of alive neighbours, or the total number of neighbours.

As an example of different observed emergent behaviour consider a union blend where the blend is only computed from alive neighbours, and as before we compute only for cells which are alive at the next iteration. We start with an initial state:



and observe a changing, but relatively steady pattern (resembling the motion of a flame) which does not grow in size using the union blend:



where the weight characteristic of the phenotype of each cell has fallen to very low.

Finally, consider applying instead an average blend under the same initial conditions:

Then we see a less steady but more active growth, with populations moving in triangular shapes away from population centres, leaving very small but steady and inactive populations behind:

The quickly-moving populations do not have a convergent weight characteristic in their phenotypes, as in the case with the union blend for the same initial conditions.

## 5 Discussion

### 5.1 Research Contribution

The motivation for combining a notion of blending with cellular automata was to investigate ways in which cellular automata could be used to model processes, where propagation rules, or genotypes, were locally defined. The main research contributions in the field of two dimensional cellular automata are

- We built and implemented a framework where local propagation experiments can be performed;
- We used the HETS system to show that the notion of blending can be used to invent new propagation rules for different genotypes;
- We invented simply definable genotypes and blends of these genotypes to show proof of concept;
- Finally, we shared the results of simulations that illustrate qualitative behaviour in one and two dimensional MetaCAs.

The primary limitation of this work is that our results are purely observational at present. For example, the early experiments seemed to provide visual evidence that blending is useful: Figure 1 is more interesting than Figure 2. The robustness of our qualitative findings have been supported by developing a range of different experiments, for example, some analogy could be drawn between the "grey areas" observed in Figure 7 for the 1D case and the red-and-white chains that develop in the 2D case under union blending.

Our results confirm the basic finding of CA research: interesting global behaviour can arise from simple rules governing local interactions, with the added twist that these rules can also arise locally. The MetaCA setting seems to offer fertile ground for further computational research into evolutionary and co-evolutionary effects.

### 5.2 Social Interpretation

One can view the propagation of cells and patterns in a 1D or 2D MetaCA as a social process, and blending as a knowledge exchange. In the 2D case, we can think of the generated diagrams as illustrations of interactions between individuals with high knowledge, skill, or social impact (high weight), and those with less (low weight). The propagation in the "union" blend shows how large numbers of individuals with low social impact outnumber those with high social impact, but those with high social impact impose the emergent structure and determine the growth of the group of individuals.

In a fundamental respect our blending rules seem to embody a thought-provoking blend of two very different kinds of "ethics." Specifically, blending seems to introduce a dynamic similar to Carol Gilligan's *ethic of care* [8], which seeks to defend the relationships that obtain in a given situation. Here this is manifested by the question "Have my neighbours already formed a consensus?" This behaviour complements the local rule, which would correspond to Lawrence Kohlberg's *ethic of justice* (cf. [3]).

As we saw in Section 4.1, we would have to work harder to find meta-rules that give rise to an "intelligent universe" or in which life (considered as symbolic computation) plays an obvious negentropic role (*après* Bergson [4]).

One strategy that has not been developed here would be to make use of a "Baldwin effect" [2, 30], to use "learning" (considered as entropy) in the phenotype layer to drive (co)evolution. More specifically, $\boxed{0}\boxed{0}\boxed{0} \mapsto \boxed{0}$ and $\boxed{1}\boxed{1}\boxed{1} \mapsto \boxed{1}$ seem to be relatively uninteresting behaviours, but they are also hard to resist under the blending dynamics as we've defined them (compare Figures 4 and 7). Can we find ways to select against them?

### 5.3 Planned extensions

One observes that under our blending rule, the two non-entropic behaviours listed above are actually selected for, not against, because they are examples of the "neighbours match" condition. Indeed, reviewing the essential features of blending in the 1D case, we can use our basic principles:

> "*If neighbours match: use their shared value as the result.*
> *If neighbours don't match: use local logic to get the result.*"

to define a 1D CA rule, if we interpret "local logic" to mean "substitute my own value as the result." Here's how we would then define blending for triplets:

| | | | | | |
|---|---|---|---|---|---|
| 0 | 0 | 0 | $\mapsto$ | 0 | *Neighbours match* |
| 0 | 0 | 1 | $\mapsto$ | 0 | *Local logic* |
| 0 | 1 | 0 | $\mapsto$ | 0 | *Neighbours match* |
| 0 | 1 | 1 | $\mapsto$ | 1 | *Local logic* |
| 1 | 0 | 0 | $\mapsto$ | 0 | *Local logic* |
| 1 | 0 | 1 | $\mapsto$ | 1 | *Neighbours match* |
| 1 | 1 | 0 | $\mapsto$ | 1 | *Local logic* |
| 1 | 1 | 1 | $\mapsto$ | 1 | *Neighbours match* |

This is Wolfram's Rule 23: and as it happens, its evolutionary behaviour is not particularly interesting. Of course, for blending at the genotype level, "local logic" can be determined by any CA. Even so, when we use blending bitwise on alleles, we only ever run the local logic on half of the cases, and moreover it always the same half, determined by a "censored" version of Rule 23.

| | | | | | |
|---|---|---|---|---|---|
| 0 | 0 | 0 | $\mapsto$ | 0 | *Neighbours match* |
| 0 | 0 | 1 | $\mapsto$ | $*$ | *Local logic* |
| 0 | 1 | 0 | $\mapsto$ | 0 | *Neighbours match* |
| 0 | 1 | 1 | $\mapsto$ | $*$ | *Local logic* |
| 1 | 0 | 0 | $\mapsto$ | $*$ | *Local logic* |
| 1 | 0 | 1 | $\mapsto$ | 1 | *Neighbours match* |
| 1 | 1 | 0 | $\mapsto$ | $*$ | *Local logic* |
| 1 | 1 | 1 | $\mapsto$ | 1 | *Neighbours match* |

Rather than using Censored Rule 23 as our template, we could instead have the template determined by phenotype data, thereby involving the phenotype as a "hidden layer" in the computation.

The standard template could be understood to be generated by locking in $\boxed{0}\boxed{0}\boxed{0} \mapsto \boxed{0}$ along with a "variation"[4] $\boxed{0}\boxed{1}\boxed{0} \mapsto \boxed{0}$ and the bitwise inverses of these. A wider class of templates could be calculated from arbitrary phenotype data by the same operations. What we would lose in abandoning the intuition associated with local blending, we may be repaid through a much more abstract but richer procedural blend, operating at the level of genotype+phenotype coevolution. At the very least, we can point to a generic space, namely the locked-in local rule which would be carried over (along with its variants) from the phenotype to the corresponding alleles.

As a simple example of cross-domain blending consider a genotype defined as in §3.3, and another which is defined by comparing the hue of just one neighbour. Their blend is a richer theory combining elements from both genotypes. CASL code expressing these concepts is given in Listing 2, and the resulting categorical diagram can be seen in Figure 9. Experimentation with more sophisticated genotypes and blends is ongoing.

---

[4] $\boxed{0}\boxed{1}\boxed{0} = \boxed{0}\boxed{0}\boxed{0} + \boxed{\ }\boxed{1}\boxed{\ }$

## 5.4 Future work

Coevolution has been understood to be relevant from both a philosophical [15] and empirical perspective [29]. Finding patterns that allow us to exploit Baldwin effects to drive the co-evolution of genotype and phenotype in the direction of intelligent behaviour is an interesting computational project. The MetaCA domain may help to show how to systematise some aspects of the search for the principles and techniques that underlie broader computational intelligence.

Expanding on the semantically simple domain of CAs, we would like to use HETS to formalise the mechanisms of social knowledge sharing and problem solving in fields like mathematics. It may be possible to encode mathematical problems in a MetaCA or cellular program and involve a group of agents in finding solutions to these problems as a society, in an emergent manner. This would be informed by ongoing empirical analysis of real problem-solving activities [20] developed in parallel to the simulation work presented here.

# 6 Conclusion

This research was inspired by the aim to build an example of computational blending that matched, to some extent, the way blending might work in social settings. One person suggests an idea, and another offers a variant of that, a third brings in another idea from elsewhere and some combination is made. The next day, things head in another direction completely. Our progress in this research project has followed this sort of trajectory: from an initial critique of blending theory ("it's not dynamic enough to be social!") to some tentative examples showing how large-scale system dynamics can be driven by local behaviour in an emergent manner. Perhaps the most interesting aspect of this research is the relationship between these emergent dynamics and the meta-rules. Whereas previous CA research has shown that complex global behaviour can be generated from a set of simple, local rules, this project gives an enticing glimpse of a future research programme that carries out a computational search for those very rules (out of the many possible) that lead to system behaviour we would recognise as "intelligent."

# 7 Acknowledgements

This research has been funded by the Future and Emerging Technologies (FET) programme within the Seventh Framework Programme for Research of the European Commission, under FET-Open Grant number 611553 (COINVENT). We would like to thank Timothy Teravainen, Raymond Puzio, and Cameron Smith for helpful conversations and pointers to literature, and Christian Guckelsberger and an anonymous reviewer for comments that improved the draft.

# Chapter 1
# Stakeholder Groups in Computational Creativity Research and Practice

**Simon Colton, Alison Pease, Joseph Corneli, Michael Cook, Rose Hepworth and Dan Ventura**

**Abstract** The notion that software could be independently and usefully creative is becoming more commonplace in scientific, cultural, business and public circles. It is not fanciful to imagine creative software embedded in society in the short to medium term, acting as collaborators and autonomous creative agents for much societal benefit. Technologically, there is still some way to go to enable Artificial Intelligence methods to create artefacts and ideas of value, and to get software to do so in interesting and engaging ways. There are also a number of sociological hurdles to overcome in getting society to accept software as being truly creative, and we concentrate on those here. We discuss the various communities that can be considered stakeholders in the perception of computers being creative or not. In particular, we look in detail at three sets of stakeholders, namely the general public, Computational Creativity researchers and fellow creatives. We put forward various philosophical points which we argue will shape the way in which society accepts creative software. We make various claims along the way about how people perceive software as being creative or not, which we believe should be addressed with scientific experimentation, and we call on the Computational Creativity research community to do just that.

## 1.1 Introduction

It seems uncontroversial to state that one of the long-term goals of research into Computational Creativity is to see creative software embedded in society: Apple's iTunes will one day compose new music for us, rather than just recommending it; Microsoft's PowerPoint will suggest jokes for a speech we're writing; videogames will be constructed on the fly to fit our preferences and mood; software will routinely make scientific discoveries; and household appliances will be endowed with creative abilities, like a refrigerator able to concoct a recipe to fit its contents. It is also uncontroversial to point out that another long-term goal of the field is to further our understanding of human creativity, both individually and in societies, through computer simulation.

Computational Creativity researchers have made steady progress towards software which creates, by employing, advancing and inventing novel Artificial Intelligence, natural language processing, graphics, audio and other techniques for creative purposes. There is, of course, much progress still to be made technically, so that software can be creative and be seen to be creative, in order for consumers to be provided with valuable artefacts and enjoyable creative experiences. In addition to the technological hurdles faced, it is clear that certain sociological issues stand in the way of progress. That is, people naturally tend towards thinking that nuts-and-bolts, bits-and-bytes machines will never have a creative spark, and different sets of people instantiate this tendency in different ways. Through much engagement and outreach, we have come to the conclusion that understanding people's conceptions of software being creative is an important tool to be used towards the long-term goal of understanding human creativity, and that favourably guiding these conceptions will be essential in bringing about the long-term goal of embedding creative software in society.

In largely separate tracks of research, we have examined how creative software is perceived by three different types of *creativity stakeholders*—people who may have something to gain or lose from software which is creative—from a practical and a philosophical perspective. We address the different types of creativity stakeholders in general in Sect. 1.3, and concentrate in the rest of the chapter on three particular types. In particular, in Sect. 1.4, we address members of the general public exposed to creative software. Following this, in Sect. 1.5, we address observer issues within Computational Creativity research itself. Finally, in Sect. 1.6 we address videogame designers, as an exemplar of a focused community of creative individuals within which creative software has begun to make an impact. We posit that, because of the different issues that each stakeholder community raises with creative software, it currently helps to study them independently, and suggest approaches to altering the perception that people have of software in these groups in different ways. However, by bringing together these strands for the first time here, we can begin to discuss more unified approaches to the presentation of software written to be autonomously creative.

Throughout this chapter, we propose hypotheses about how each set of stakeholders perceive software as being creative or not, based on practical experiences,

Author Proof

philosophical studies and theoretical advances. We believe that our arguments in favour of these claims are sufficiently strong for them to be taken to the next level and tested scientifically through observer-based experimentation—and that the hypotheses provide an agenda the Computational Creativity research community cannot ignore. To conclude in Sect. 1.7, we suggest some practical ways in which these claims (which are presented as numbered hypotheses) could be investigated. In order to explain and support the claims we make, in the next section, we first present a philosophical perspective on the notion of creativity, which will introduce ideas that underpin the material in the rest of the chapter.

## 1.2 A Perspective on Creativity

We hold that creativity is a *secondary* and *essentially contested* quality of a person, and that linguistic usage of terms related to creativity can often be declarative illocutionary speech acts. We unpack these assertions below. Firstly, we believe that attributions of creativity are contextualist, having no truth value which is independent of context, perception and interpretation. In this way we see creativity attributions as analogous to the Lockean notion of a secondary quality [1]. Locke distinguished *primary* and *secondary qualities*, where the former are taken to be intrinsic to an object, for example, its mass, and the latter are understood to be perception-dependent, for example, colour. While these Lockean qualities are directly tied to sensory perception, as opposed to the aesthetic and social category of creativity, the distinction is still a useful one here, since it highlights different types of properties. Dennett's intentional stance [2] is also of interest here: we may adopt a "creativity stance" towards a person and interpret their work *as though they were being creative*, in order to better understand (rather than predict) their behaviour. Likewise, we may find that the "creativity stance" provides a new way of understanding the behaviour of a piece of software which goes beyond the physical details of the program.

Gallie introduced *essentially contested concepts* as those for which "the proper use . . . inevitably involves endless disputes about their proper uses on the part of their users" [3, pp. 169], to which Gray added that the disputes ". . . cannot be settled by appeal to empirical evidence, linguistic usage, or the canons of logic alone" [4, pp. 344], and Smith noted that ". . . all argue that the concept is being *used inappropriately* by others" [5, pp. 332]. In the *Cambridge Handbook of Creativity*, Plucker and Mabel assert that:

> . . . despite the abundance of definitions for creativity and related terms, few are widely used and many researchers simply avoid defining the relevant terms at all. [6, p 48]

Clearly, certain notions such as *art* are essentially contested concepts, looking at the multitude of articles written each year in the popular and cultural press asking: "But is it Art?" Indeed, Gallie points out that the statement: "This picture is painted in oils" can be disputed whilst the disputants nevertheless agree on the proper usage

UNCORRECTED PROOF

Author Proof

of the terms involved, whereas the assertion "This picture is a work of art" is likely to be contested

> . . . because of an evident disagreement as to—and the consequent need for philosophical elucidation—of the proper general use of the term "work of art" [3, pp. 167].

As a recent example, the question of whether videogames should be classed as art was raised by a Guardian art critic [7], to which the Guardian games editor responded:

> Here is a good way to tell if a critic is having a moment of madness: they will attempt to define art. The greatest philosophers in history have floundered on the question, many simply avoided it altogether, preferring to grapple with more straightforward questions—like . . . the existence of God. Art is ethereal, boundless, its meaning as transient as the seasons. When you think you have grasped it, it slips through your fingers [8].

While this is only one example, it serves as an exemplar of the kinds of debates that occur daily about the nature of art. While it is true that the preoccupation with expressing creativity is a relatively modern aspect of the visual arts, if the notion of *art* is indeed essentially contested within our culture, then the notion of the *creativity* that went into producing a given artwork should be seen accordingly. In particular, a selection of criteria for what counts as creativity is required in any coherent scheme for understanding and evaluating creativity in art. This is the perspective advanced by Jordanous [9], with which we agree—although we also agree with her point that there is unlikely to be broad and lasting agreement about just what the precise criteria of creativity actually are. We can further justify the idea that proper usage of the term *creativity* involves endless debate about its proper usage by reference to the multitude of volumes written about improving, managing and assessing creativity in people, organisations and society. Indeed, as a society, we are better off if we do not agree about what creativity means—in the sense that the disputes we have about this are an engine for change and progress, and it would surely be stultifying if we all suddenly agreed on this most important of concepts. While it is problematic for various areas of study—not least Computational Creativity—that creativity is an essentially contested quality of any person, it is something we need to embrace and even celebrate. For more in-depth discussion of these issues, see Jordanous [9, Chap. 3]. We may ask, in practice, what does it mean to *say* someone or something is "creative"? Austin informally introduced the notion of an *illocutionary act* as a locution that also serves to perform another action [10]. Searle further categorised such speech acts into: *assertives*, *directives*, *commissives*, *expressives* and *declarations* [11]. *Declarations* in particular are understood to change reality in accordance with the proposition stated. An example of such a speech act is: "I pronounce you husband and wife." We believe that—in certain circumstances—people can bestow the reality of a person being creative simply by stating it. To see this, we recall the contested nature of creativity, and the assumption that there is no general consensus about what makes someone creative. It follows that people who are not particularly invested in the creativity (or lack thereof) of someone else may be swayed by the declarative speech act of a third party in a position of authority. When Nicholas Serota, long time director of the Tate art museums and galleries, says that a piece is a great work of art, that work

UNCORRECTED PROOF

Author Proof

becomes (at least temporarily) a great work. When he states that a particular artist is unusually creative, who are we to argue? Given that the sentence 'X is creative' is often shorthand for: 'Most people agree that they perceive X to be creative', such authorities can essentially bring into being the creativity of X, regardless of whether X perceives him/herself as creative or not.

## 1.3 Communities of Creativity Stakeholders

In order to understand the different groups of creativity stakeholders, the relationships between them, and the ways in which meaning is continually being created, negotiated and re-created, we can look to sociology. In Latour's *Actor Network Theory* [12], he describes such stakeholders and diverse social groups as actors in a network. Meaning is created socially via actors who cluster into diverse stakeholder groups. These groups are in constant flux, as relationships, actors and ideas within the groups change and come into conflict with each other. Latour holds that understanding such dynamics in the network is essential to understanding processes of innovation and knowledge-creation in science and technology. The process by which a network is formed and comes to be represented as a single entity is called *translation*, and is a key concept in the Actor Network Theory. Translation consists of various phases: the initial formation of a programme and identification of actors in a new network with a novel, shared goal (*problematisation*); the strengthening of the network via formal and informal means (*interessement*); ways of evolving the network and providing structures for new members to join (*enrolment*); and acquiring the resources and power to build an effective institution which can achieve its goal (*mobilisation*).

In the case of Computational Creativity, relevant creativity stakeholders include researchers, the wider AI community, funding bodies, experts in the psychology of human creativity, neuroscientists, artists, art critics, journalists, philosophers, educators, the public, and so on. Each group has accompanying visions, beliefs and goals, in which they have, to a varying degree, invested (and which, to a varying degree, define them as a group). We hold that understanding such different perspectives and their interactions is essential if software is ever to be deemed creative by mainstream consumers of cultural artefacts. In this section, we consider these stakeholder groups and in particular use Latour's notion of translation to look at how Computational Creativity researchers have evolved into a community. We also look at some of the relationships between the groups, both in the context of Computational Creativity and the wider scientific arena.

### *1.3.1 The Computational Creativity Stakeholders*

Members of the Computational Creativity community are largely people with a background in Artificial Intelligence or computer science and an interest in creativity.

UNCORRECTED PROOF

Author Proof

They are usually professional academics with the infrastructure of a university supporting them. AI is itself a young field—originating in the 1950s—and, since initial attempts to build general intelligence machines, has fragmented into many different specialisations and subdisciplines: once established, these then form the *internal environment* for any new area, in terms of providing ideas, methods and concepts, and at times, competition. Academic measures of the health of such subdisciplines include the amount of funding awarded, the number of lectureships or professorships in the field, the existence of a journal and an international conference series, and other scientifically respectable incentivisation schemes and recognition.

It was against this backdrop that AI researchers with an interest in creativity found themselves in the late 1990s. Given their background, they were not only accustomed to the idea that machines can be intelligent, but their very livelihood depended on that premise. So it was not, perhaps, such a huge leap to the idea that machines can be creative. However, since there was no infrastructure supporting research into Computational Creativity, early researchers largely had to establish their reputation in different (possibly related) areas of AI and build up the Computational Creativity community almost on their own time, sometimes taking considerable career risks to do so.

Latour's notion of *translation* can help us to understand how the community formed. *Problematisation* occurred when a few core people identified the goal of building creative software as a subdiscipline of AI. Between them, they had the influence and organisational power to make *Creativity in AI and Cognitive Science* the theme of the AISB'99 Convention (co-chaired by Geraint Wiggins, Helen Pain and Andrew Patrizio). This featured a keynote address by Margaret Boden, a cognitive scientist known for her popular writing on creativity in people and in machines [13, 14]. The initial symposium was followed up by four further events[1] held at AISB'00 - AISB'03, and a series of workshops on creative systems at major AI conferences. We present an extract from the editors' introduction to the Proceedings of the Symposium on Creative and Cultural Aspects of AI and Cognitive Science, held at AISB in 2000 in Fig. 1.1. This was the *interessement* phase. These were further consolidated with the International Joint Workshops on Computational Creativity (IJWCC), held 2004–08, during which time the community grew from twenty, or so, to double that (*enrolment*). Finally, the community was considered healthy enough, strong enough and large enough to launch the first International Conference on Computational Creativity in 2010. For a history of the field up to this stage, see [15] in a special issue of the AI magazine on Computational Creativity.

The community continues to evolve and grow, with the series having recently held its Fifth Annual International Conference (2014), with around 90 delegates. In order to organise and guide the international series, a Steering Committee was set up consisting of anyone who had chaired an IJWCC event, and they formed the Association for Computational Creativity (ACC) in 2010 and set out rules which enabled new members to join and old members to leave the Association (*mobilisation*). Landmark

[1] *Creative and Cultural Aspects of AI and Cognitive Science* (2000) and then simply *AI and Creativity in Arts and Science* (2001–2003).

> Following on from the successful AISB'99 Convention, whose theme was the study of creativity in AI and Cognitive Science, the purpose of this symposium is to bring together researchers interested in all AI and cognitive aspects of creativity and cultural enterprise. The aim of holding one unified meeting, instead of several simultaneous smaller ones, is to promote communication between those studying different aspects of creativity, and this has been mostly achieved: the papers (and the corresponding presentations) are for the most part grouped by their relation to creativity in general, rather than to a particular domain. The exceptions to this are two papers on important low-level aspects of modelling musical creativity.
>
> The four sections which have naturally arisen, then, are headed Exploratory Creativity, Modelling & Supporting Creative Processes, Techniques for Modelling Musical Creativity, and Methodology & Evaluation.

**Fig. 1.1** An excerpt from the preface of the Proceedings of the Symposium on Creative and Cultural Aspects of AI and Cognitive Science, held at AISB in 2000, written by Geraint Wiggins. Note the 'natural' emergence of themes within the field, although of course these are very much subject to the Call for Papers, the communities who received the call, the instructions given to the reviewers, the reviewers themselves and the editor's vision

events during this time included the first ever award of a Chair in Computational Creativity (to Geraint Wiggins, in 2004, by Goldsmiths, University of London) (only one of two—the other being held by Simon Colton also at Goldsmiths, University of London, awarded in 2013); the first PhD with Computational Creativity in its title (Anna Jordanous, University of Sussex, 2012 [9]) and the first NSF and EU calls for proposals in Computational Creativity (*CreativeIT, NSF Program Solicitation 09–572* [16] and *Objective ICT-2013.8.1, Technologies and scientific foundations in the field of creativity* [17, p. 81]). The process has been carefully managed throughout, with an eye on political as well as intellectual developments. Social factors have also played a key role, being inextricably linked to internal development of scientific knowledge [18].

### *1.3.2 Other Creativity Stakeholders*

Each of the other stakeholder groups will have a similarly fascinating history. Some, such as the EU funding body, are tightly bound and have a formal definition of themselves and their goals. Others, such as the general public—for whom the concept of *translation* is meaningless—are much more loosely defined. Of note is who the decision makers are in each of these groups. In the Computational Creativity community, it is clear that a few people have had a huge influence, and it is likely that this is also the case for other groups of stakeholders. It may be worth considering these in detail, especially from a point of view of motivation and power. For instance, Boden's way of seeing creativity dominated the first decade of the community growth. Likewise, a few core individuals working for the EU had the influence to prioritise research into Computational Creativity, and to fund around €10 m worth of projects.

UNCORRECTED PROOF

Author Proof

- **The general public**

When describing what they do, to a layman, most researchers into Computational Creativity will probably have experienced reactions such as: "A computer that is creative might be dangerous—it might kill us"; "Creativity is a celebration of humanity, and the very idea of Computational Creativity cheapens that"; "I read a poem or listen to music to communicate with another human being. I don't want to communicate with a computer, I want a live human connection", and so on. It is important to determine where these ideas come from, whether they are grounded in anything, whether we should try to counter them, and if so, how? While such emotional responses are not necessarily negative, it might be the case that they hinder reasoned debate. Public perception of Computational Creativity derives from multiple sources, including journalistic coverage (or lack of it), science fiction narratives, opportunities to consume computationally created artefacts and so on. We look further at observer issues in the general public in Sect. 1.4.

- **Fellow creatives**

Creative people sometimes voice the worry that "Computers are going to put us out of a job". This group is similar to the general public in terms of influences and attitudes. It seems that artists might be being encouraged to worry about software replacing them, because such sensationalist stories sell newspapers. We study a particular community of creative people, namely videogame designers in Sect. 1.6.

### *1.3.3 Relationships Between the Different Stakeholder Groups*

There have been several interactions between the Computational Creativity community and members of the public and fellow creatives. For instance, Colton and Ventura hosted a festival of Computational Creativity in 2013, *You Can't Know my Mind* [19], and other events have followed on from this. Historical relationships between scientists and the public can also elucidate current interactions. In other fields, there have been some explicit campaigns to manufacture doubt, by parties who are threatened by specific scientific advances. For instance, the tobacco industry tried to discredit and discourage the notion that smoking is bad for our health; likewise the fossil fuel industry did the same in the case of global warming. Here we see that a few powerful actors can sometimes bring an entire body of established scientific knowledge into question.

Ravetz argues that scientific ignorance may in some ways be as prone to social construction as scientific knowledge [20, 21], cited in [22, p. 37]. Stocking and Holstein [22] explore different perceptions that journalists have of their roles, concluding tentatively that journalists construct scientific ignorance consistent with their own interests. Even without such dark agendas, there are other examples from the history of science in which public perceptions conflict with scientific thinking and have been managed, or controlled, in order to bring them into line with current scientific results. Famous examples in which scientific advances have challenged our image of ourselves and our universe include Copernicus's heliocentric model,

UNCORRECTED PROOF

Author Proof

which challenged our view that the earth is the centre of the universe; Darwin's theory of evolution, which challenged concepts of what it means to be human, to be distinct from other animals, and the notion that our existence has a higher purpose; and Lemaître et al.'s Big Bang theory, which challenged the view that the universe is a stable, stationary entity. In all of these cases the scientists faced their own challenges of reconciling their findings with their religious or world views, and then a process of outreach was necessary in order to gain wider social acceptance. Thus, we see Thomas Huxley—"Darwin's bulldog"—promoting Darwin's theory in the face of many varied and negative responses to it (some of which are recorded in [23]) and helping it to gain wider acceptance, transitioning from scientific to social fact. Today, people in the fields of genetically modified food and stem cell research endeavour to gain wider social acceptance in the form of media coverage and well-funded outreach programmes aimed at educating both school children and the wider community.

Computational Creativity is in a particularly difficult position, since its main research question concerns an essentially contested concept. On certain understandings, the question "can machines be creative?" may be answered negatively, without further elaboration or debate. Thus, we see part of the job of the Computational Creativity community consisting in the delivery of outreach programmes, in which creative software is demonstrated and explained, and the artefacts it has produced exhibited in a setting in which consumers of creative artefacts might begin to appreciate them. In [24], Franzen et al. explore the impact that such dissemination activities can have on scientific progress, and argue that the right name, image or metaphor has the power to make or break relations between a scientific discipline and the public. For instance, consider Dolly the sheep from the Roslin Institute in Edinburgh and Ida the primate fossil from the Messel Pit in Germany. These names make it easier for the discoveries to be visualised and discussed. Arbib and Hesse go further, stating that "scientific revolutions are, in fact, metaphoric revolutions" [25, p. 156], cited in [26, p. 5].

In addition, then, to sociological narratives, it is important to consider language use by each stakeholder group. The role of spin doctors is well-known in the political arena, in which those who bestow power are influenced in their thinking by vocabulary, metaphors and frames. In our case, the public have the power to bestow or withhold the word "creative" when describing software. Thus, we need to consider the language that we use. Lakoff [27] argues that we fit new information into pre-existing frames, which are built up slowly over time, and if we don't have appropriate frames, then we might misunderstand the information. Using the wrong frame, which is triggered by specific vocabulary, even to deny a message, only reinforces the frame. Thus, rather than trying to argue that "creative software is not scary", we should build up our own vocabulary, frames and metaphors for thinking about it.

**Hypothesis 1** Different stakeholder groups (including Computational Creativity researchers, the general public, domain creatives, psychologists, philosophers, educators, critics, journalists, bureaucrats, etc.) assess creativity in software differently, and there is no one-size-fits-all approach to presenting what software does and what it produces in the best way to increase perception of creativity.

UNCORRECTED PROOF

Author Proof

Given this, we believe it is currently appropriate to study stakeholder groups separately, as we do in the following sections.

## 1.4 Observer Issues with the General Public

We introduce here three notions, namely *essential behaviours*, *the humanity gap* and *software accounting for its actions*. We believe these are important in understanding how people generally react to the idea of software being creative, and thus are important in managing and shaping those reactions. To end the section, we present a case study in handling public perception of creativity in software, and we introduce another notion, namely that of *accountable unpredictability*.

A working definition of the field of Computational Creativity research as a subfield of Artificial Intelligence research given in [28] is as follows:

> The philosophy, science and engineering of computational systems which, by taking on particular responsibilities, exhibit behaviours that unbiased observers would deem to be creative.

While this definition is not universally accepted (with a challenge to focus on system-level creativity rather than individual responsibilities given in [29]), variations of it have been used to describe the field for many years.

The usage of the word 'unbiased' in the above definition hints at a problem encountered in evaluating projects where generative software produces *artefacts* (poems, paintings, sonatas, recipes, theorems, etc.) for human consumption. In particular, people generally have natural biases against, but also occasionally in favour of, artefacts produced by computers over those produced by people. In particular, negative, so called 'silicon', biases have been observed under experimental conditions [30, 31]. Hence, in stipulating that observers must be unbiased, the definition above emphasises a scientific approach to evaluating progress in the building of creative systems, whereby experimental conditions are imposed to rule out, or otherwise cater for, such biases. One such experimental setup is the *Turing-style comparison test*, where computer-generated and human-produced artefacts are mixed and audience members make choices between them with zero context given about the processes involved in their production. It is seen as a milestone moment if audiences cannot tell the difference between the artefacts produced by people and those produced by a computer. We believe there are many problems in the application of such tests in the general context of presenting the processing and products of creative software, as expanded in the subsections below.

### 1.4.1 Essential Behaviours

We suggest not asking people if they believe software is behaving creatively, but rather concentrating on whether they perceive the software to be acting *uncreatively*. Using our standpoint above that the notion of creativity is essentially contested [3], we expect that no matter how sophisticated our software gets, we will not see consensus on such matters. However, we have found that people agree much more on notions of uncreativity: if a program doesn't exhibit certain behaviours onto which certain words can be projected, then it is easy to condemn it as being uncreative. Building on the foundational arguments given in [32], we propose that audience members can too easily label software as uncreative if they are unable to project any of the following words onto the behaviours they perceive software to be exhibiting:

> skill, appreciation, imagination, learning, intentionality, accountability, innovation, subjectivity and reflection

We have found that assessing the level of projection of these words onto the behaviours of software can help us to gauge people's opinions about (the lack of) important higher-level aspects of software behaviour, such as autonomy, adaptability and self-awareness. Note that we make no claim about the above behaviours being sufficient for a perception of creativity: a necessary set of behaviour types for avoiding the uncreativity label is not the same as a sufficient set of behaviour types for gaining the creativity label. This mis-interpretation of our aims for highlighting the above essential behaviours has propagated somewhat, for instance in [33].

**Hypothesis 2** Creativity in people and software is essentially contested and secondary, and hence it might be advantageous to work on people's perception of *uncreativity* in software, as this is easier to predict/manage. Software exhibiting the essential behaviour types highlighted above is necessary for it to avoid being labelled as uncreative. Eventually, when there are no good reasons to label software as uncreative, people may choose to label it as creative.

### 1.4.2 The Humanity Gap

One could argue that, given the particularly human-centric nature of creativity, and that a human connection is paramount in much of the arts, it is simply inappropriate to use the term 'creative' to describe software. The status quo is that we currently haphazardly apply human terminology related to creativity to software, which often requires the projection of other human qualities onto software, such as it being juvenile, which is inherently error prone, given that computers are patently not people. Another option is to ignore the non-human nature of software and concentrate on what it produces, rather than on what it is, or what it does. To begin to address the kind of silicon biases described above, researchers often compare the interpretation of computer-generated and human-produced artefacts in a rather extreme "blind

UNCORRECTED PROOF

Author Proof

experiment" situation in which knowledge about the personality of the artist and their practice is entirely missing. The philosophical grounding of such an approach [34, 35] matches the motivation of several art movements [36, 37] and many individual artists who have expressed a desire for their work to be taken at face value (see [38] for examples and further discussion).

We argue that in modern culture, a curious thing can happen when artists attempt to remove all reference to themselves and their process from discussions about the artistic (and commercial) value of their work. That is, in the absence of such information, people may tend to fill in the gaps about personality and process, and may do so in ways which bolster the credibility of an artist and increase the perceived value of his/her works. Indeed, one could argue that—in the same way that artists invite people to interpret the imagery in artworks in their own way by not prescribing what people should see/read/hear, in refusing to provide meta-level details about personality and process, artists, writers and musicians are actually (purposefully or not) inviting art lovers to invent interesting and engaging back-stories about who they are and what they do.

In such a context of non-disclosure, the comparison of the situation for computer-generated artefacts with the situation for human-produced artefacts is not particularly favourable. The vast majority of people have little or no idea about programming or programs, and may even harbour a desire not to find out about these things. Thus, when invited to assess a computer generated painting or poem, say, without background knowledge, they are denied any opportunity to invent a back-story, as they cannot project personality traits or romantic situations onto the computer, and cannot enter into any dialogues. More importantly, this situation can lead to people realising how much they value the human connection, whether actual or imagined, in such situations. We posit that there is a *humanity gap* that must be faced by Computational Creativity researchers who want their software to enhance society by being creative for artistic and utilitarian purposes.

Turing-style experiments, which epitomise the practice of non-disclosure, are intended to reduce variables so that a scientific study of the value of computer generated artefacts can be undertaken. One could argue that these contexts are intended to help people realise how much they value the aesthetic appeal of art, literature and music, regardless of other factors. This may be true, but we believe that such tests can actually help people realise how little they can relate to the computational origin of artefacts. In [39], we raise other issues with Turing-style comparison studies: in particular, we suggest that they encourage naïvety and pastiche generation in creative software. As a final point, it is clear that such experimental conditions are not sustainable if we are to enhance society with creative software. In the long term, biases about machine creation need to be embraced and managed, rather than factored out through experimental setups.

**Hypothesis 3** Turing-style comparison tests serve to highlight the humanity gap, and while they might serve short-term scientific gain, they are damaging to the long-term goal of embedding creative software in society.

UNCORRECTED PROOF

Author Proof

### 1.4.3 Software Accounting for Its Actions

We argue in [32, 40] that people take into account how a person or software operates when they assess the value of the output it produces. To address this issue, we advocate a development path to follow when building creative software: (i) the software is given the ability to provide additional, meta-level, information about its process and output, e.g., giving a painting or poem a title (ii) the software is given the ability to write commentaries about its process and its products (iii) the software is given the ability to write stories—which may involve fictions—about its processes and products, and (iv) the software is given the ability to engage in dialogues with people about what it has produced, how and why. Indeed, giving software the ability to discuss its creative works would mirror Turing's original proposal for an intelligence test [34] to a greater extent than tests focusing only on consumer perception of artefacts. As a preliminary example, in [41], we demonstrated a poetry generation system which is able to provide commentaries about its poetry, and how and why it produced a particular poem.

As we discuss in [42], in a computational setting, there are advantages to software being immersed in environments where serendipity might occur. However, accounting for lucky events that trigger creative acts may actually lessen the celebration and hence the impact that the acts have. It is important to note that people tend not to describe their processes and products in the explicit way we advocate for software, preferring to maintain some level of mystery. Nevertheless, we believe that, at this stage in the development of computationally creative systems, it is important to address the humanity gap—without aspiring to eliminate it. *Framing* [40] serves to highlight that intelligent processing was used to produce artefacts, which is an important first step. Given that audience members will typically not be able to come up with an interesting backstory without some scaffolding, positive acts of framing are likely to have more fruitful impact than an overall air of mystery.

Another possible way to address the humanity gap is to manage people's expectations about the level of humanity they will encounter through a computationally produced artefact. In the same way that when people buy an *e-book* they know they are not going to get a physical object, we advocate telling audiences that they are reading a *c-poem*, and hence—in the knowledge that it was produced computationally—they will get a reduced human connection. We can go further in *re-imagining* traditional artefacts, for instance in suggesting that a c-poem is actually a doublet of texts, one which resembles a traditional poem and another which provides a commentary about the motivations, actions and results of the software's processing. We believe this will highlight the humanity gap, but that it will do so in such a way as to help people to engage with and appreciate the creative process, and better enjoy the artefacts produced by software.

**Hypothesis 4** The humanity gap can be addressed by re-imagining the nature of creative artefacts, to manage expectations of humanity. In particular, it is advantageous for software to account for its processes and products through additional material such as a commentary.

Author Proof

### 1.4.4 A Case Study in Automated Portraiture

As part of an exhibition with The Painting Fool[2] system [43] in 2013, we enabled the software to produce portraits for people live in a gallery, as described in [19]. Managing the expectations and perceptions of the observers was a key aspect of this project. To this end, we hung posters describing the behaviour of the software as exhibiting aspects of intentionality, imagination, skill, appreciation, reflection and learning (six of the essential behaviours described above). Moreover, the software's actions and output were tailored to support the perception of these behaviours and an impression of creativity in the software by observers present in the exhibition, especially those sitting for a portrait.

Portraits were painted with people sitting in front of a laptop. It was immediately made clear that (i) the software was modelling a 'mood' to direct its painting, and (ii) the sitter was very much a tool for the software, not the other way around. This was achieved by opening remarks from the software such as: "Thank you for being my model. I'm in a negative mood right now, so I would like you to express a sad emotion." This was followed by The Painting Fool explicitly directing the sitter, while video recording them. A still image was then extracted where the sitter was expressing an emotion. Machine vision techniques were applied to remove the background, into which was substituted one of 1,000 abstract art images, to which one of 1,000 image filters was applied. The filter was chosen to increase the chances that the resulting image might reflect a changing simulated mood gained through reading newspaper articles, as described in [19]. The same filter was applied to the face of the sitter placed in the foreground, producing in a few seconds an image conception, or sketch for the portrait, such as the first image of Fig. 1.2.

Following this, a canvas appeared on screen, and a hand holding either a pencil, paint brush or pastel stick made virtual marks on the canvas leading to a non-photorealistic rendering of the background and foreground of the portrait, taking between 2 and 10 minutes, depending on the style. An example portrait is given at the bottom of Fig. 1.2, which was printed and given to the sitter, along with the commentary (the whole of Fig. 1.2). The most important aspect of the commentary is the expression of intention, by first showing a conception of the type of portrait the software aimed to produced, then showing what it produced and finally analysing and criticising—using machine vision techniques described in [44]—its results with respect to its aims.

The purpose of the exhibition was cultural, not scientific, and no experimentation was undertaken. From our experience, however, we contend that the behaviours exhibited by the software and explained in poster form enabled people to be surprised by the resulting portrait (and many of the 100 or so sitters in the exhibition were very surprised), while still projecting creativity onto the software. This upheld the aim of the *You Can't Know my Mind* exhibition: as it used some intelligence, and could explain its actions, it was somewhat appropriate to employ the word 'mind' with reference to The Painting Fool. However, as the process was unpredictable due to

the dynamic nature of the software's changing mood, it was impossible to know this mind, and people realised that some software is written not to be a tool, but to be a creative individual. In fact, when in the most negative of moods, The Painting Fool refused to paint a portrait and sent the (often shocked) sitter away, citing a particularly depressing keyphrase in a particularly distressing newspaper article that it had recently read.

In these cases, The Painting Fool pointed out explicitly: "No random numbers were used in coming to this decision". This is because we feel that *accountable unpredictability* is important for creative systems. That is, we have found that when people realise that a certain important event has happened or an important artefact has been produced because of a random act, any dialogue (perceived or real) comes to an abrupt halt, and detracts from the creative experience. In contrast, unpredictability through accountable actions such as reading newspaper articles can add a great deal to a creative experience, at the very least by providing additional talking points.

**Hypothesis 5** Accountable unpredictability enhances the experience people have when told about software creating an artefact, whereas random number based unpredictability detracts from the experience.

## 1.5 Formally Capturing Progress in Creative Systems

Naturally, another major set of stakeholders in the notion of software being creative are the Computational Creativity researchers who aim to write such systems, and use them to study creativity in people and machines. As they are familiar with the issues of simplistic arguments for and against creativity in software, these stakeholders require more formalism in any argumentation put forward to support the hypothesis of increased creativity in software.

We have focused on formalising the general notion of *progress* in Computational Creativity research. To do this, we first introduced the FACE and IDEA descriptive models in [45, 46]. The FACE model categorises generative acts by software into those at (g)round level, during which base objects are produced, and (p)rocess level, during which methods for generating base objects are produced. These levels are sub-divided by the types of objects/processes they produce: $F_g$ denotes a generative act producing some framing information, $A_g$ denotes an act producing an aesthetic measure, $C_g$ denotes an act producing a concept and $E_g$ denotes an act producing an example of a concept. Generative acts producing new processes are defined accordingly as $F_p$, $A_p$, $C_p$ and $E_p$. Tuples of generative acts are collated as *creative acts*, and various calculations and recommendations are suggested in the model with which to compare creative systems. We developed the IDEA model so that creative acts and any impact they might have could be properly separated. We defined various stages of software development and used an ideal audience notion, where people are able to quantify changes in well-being and the cognitive work required to appreciate a creative act and the resulting artefact and/or process.

UNCORRECTED PROOF

Author Proof

The majority of researchers develop software using only themselves as an evaluator, because observer-based models are too time-consuming to use on a day-to-day basis. These informal in-house evaluation techniques generally do not capture the global aims of the research project, or of the field (e.g., producing culturally important artefacts and/or convincing people that software is acting in a creative fashion). This can lead to situations where systems are presented as feats of engineering, with little or no evaluation at all [9]. In [47], we argue that assessing *progress* is inherently a process-based problem, and hence we concentrate our formalism on processes, tempered with aspects of artefact evaluation. In the subsections below, we present this formalism with worked examples, followed by a case study describing the development of an evolutionary art system.

### 1.5.1 Formal Assessment of Progress

We combine the most useful aspects of the IDEA and FACE models, the list of essential behaviours described in Sect. 1.4.1, and certain aspects of assessing artefact value in a diagrammatic formalism for evaluating progress in the building of creative systems. We focus on the creative acts that software performs, the artefacts it produces and the way in which audiences perceive it and consume its output. We simplify by assuming a development model where a single person or team develops the software, with various major points where the program is sufficiently different for comparisons with previous versions. We aim for the formalism to be used on a daily basis without audience evaluations, to determine short term progress, but for it also to enable fuller audience-level evaluations at the major development points. We also aim for the formalism to help determine progress in projects where there are both *weak* and *strong* objectives, focused, respectively, on the production of increasingly higher valued artefacts, and on increasing the perception of creativity people have of the system. We found that the original FACE model didn't enable us to properly express the process of building and executing generative software. Hence another consideration for our formalism is that it can capture various timelines both in the development and the running of software in such a way that it is fairly obvious where the programmer contributed creatively and where the software did likewise.

### 1.5.2 Diagrammatic Capture of Timelines

Taking a realistic but abstracted view of generative software development and deployment, we identify four types of timeline. Firstly, generative programs are developed in **system epochs**, with new versions being regularly signed off. Secondly, each process a program undertakes will have been implemented during a **development period** where creative acts by programmer and program have interplayed. Thirdly, at run-time, data will be passed from process to process in a series of creative and

UNCORRECTED PROOF

Author Proof

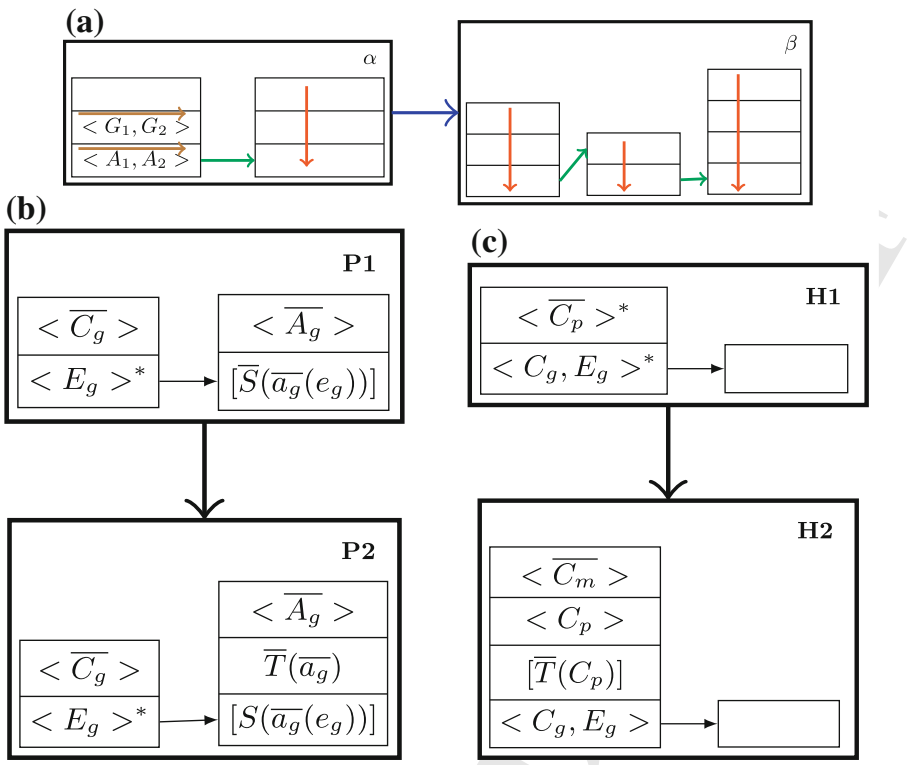

**Fig. 1.3** **a** Key showing four types of timelines **b** progression of a poetry system **c** progression of the HR system

administrative **subprocesses** performed by software and programmer. Finally, each subprocess will comprise a sequence of generative or administrative **acts**.

We capture these timelines diagrammatically: the four different kinds of transitions are highlighted with coloured arrows in Fig. 1.3a. The blue arrow from box $\alpha$ to $\beta$ represents a change in epoch at system level. The red arrows overlapping a *process stack* represent causal development periods. The green arrows represent data being passed from one subprocess to another at run-time. The brown arrows represent a series of generative/administrative acts which occur within a subprocess. Inside each subprocess box is either a ⟨creative act⟩ from the FACE model (i.e., a sequence of generative acts), or an [administrative act] which doesn't introduce any new concept, example, aesthetic or framing information/method. Administrative acts were not originally described in the FACE model, but we needed them to describe certain progressions during software development. For our purposes here, we use only $T$ to describe a translation administrative act often involving programming, and $S$ to describe when an aesthetic measure is used to select the best from a set of artefacts. We employ the FACE model usage of lower-case letters to denote the output from the corresponding upper-case generative acts. Furthermore, we extend the FACE notion of (g)round and (p)rocess level generative acts with (m)eta level acts during which process generation methods are invented. As in the original description of the FACE model, we use a bar notation to indicate that a particular act was undertaken by the programmer. We use a superscripted asterisk (*) to point out repetition.

UNCORRECTED

Author Proof

As a simple example diagram, Fig. 1.3b shows the progression from poetry generator version P1 to P2. In the first version, there are two process stacks, hence the system works in two stages. In the first, the software produces some example poems, and in the second the user chooses one of the poems (to print out, say). The first stack represents two timesteps in development, namely that (a) the programmer had a creative act $\langle \overline{C_g} \rangle$ whereby he/she came up with a concept in the form of some code to generate poems, and (b) the software was run to produce poems in creative acts of the form $\langle E_g \rangle^*$. The second stack represents the user coming up with an idea for an aesthetic, e.g., preferring lots of rhyming, in creative act $\langle \overline{A_g} \rangle$, and then applying that aesthetic $\overline{a_g}$ him/herself to the examples produced by the software, in the *selection* administrative act $[\overline{S}(\overline{a_g}(e_g))]$, which maps the aesthetic $\overline{a_g} : \{e_g\} \rightarrow [0, 1]$ over the generated examples, and picks the best one. In the $P2$ version of the software, the programmer undertakes the *translation* act $[\overline{T}(\overline{a_g})]$, writing code that allows the program to apply the rhyming aesthetic itself, which it does at the bottom of the second stack in box $P2$.

Figure 1.3c shows a progression in the HR automated theory formation system [48] which took the software to a meta-level, as described in [49]. HR operates by applying production rules which invent concepts that categorise and describe input data. Each production rule was invented by the programmer during creative acts of the type $\langle \overline{C_p} \rangle$, then at run-time, HR uses the production rules to invent concepts and examples of them in $\langle C_g, E_g \rangle^*$ acts. In the meta-HR version, during the $\langle \overline{C_m} \rangle$ creative act, the programmer had the idea of getting HR to form theories about theories, and in doing so, generate concept-invention processes (production rules) in acts of the form $\langle C_p \rangle$. The programmer took meta-HR's output and translated it via $[\overline{T}(C_p)]$ into an implemented production rule that HR could use, which it does at the bottom of the stack in box H2.

### 1.5.3 Comparing Diagrams and Output

Examining the transition from one epoch-level diagram to another should provide some shortcuts to estimate audience reactions, especially when these are linked to strong objectives. As with the original FACE model, the diagrams make it obvious where creative or administrative responsibility has been handed over to software, namely where an act which used to be barred has become unbarred, i.e., the same type of generative act still occurs, but it is now performed by software rather than programmer. For instance, this happened when the $\overline{S}$ became an $S$ in Fig. 1.3b and when the $\overline{C_p}$ became a $C_p$ in Fig. 1.3c. At the very least in these cases, an unbiased observer would be expected to project more autonomy onto the software, and so progress in the strong sense has likely happened. In addition, the diagrams make it obvious when software is doing more processing in the sense of having more stacks, bigger stacks or larger tuples of acts in the stack entries. Moreover, the diagrams make it clear when more varied or higher-level creative acts are being performed by

UNCORRECTED PROOF

Author Proof

the software. All of these features have the potential to convince audience members that software is being more sophisticated, and can be taken as a preliminary indicator of progress.

When dealing with actual external evaluation, where people don't know what the software does, we suggest that the diagrams above (or verbalisations/simplifications of them) can be used to describe the software to audience members, to explain what the software does, and what the programmer has done in the project. Audience members can then be asked whether they would project any of the essential behaviours from Sect. 1.4.1 onto any of the creative acts undertaken by the programmer or by the system. Thus, one method for estimating progress from version $v1$ of a creative system to version $v2$ that takes into account features of both processing features and artefact quality would be:

- show audience members the diagrams for $v1$ and $v2$ as above, and explain the acts undertaken by the software, then
- show audience members the output from $v1$ and $v2$, and,
- ask each person to compare the pair of product and process for $v1$ with that of $v2$.

A statistical analysis could then be used to see whether the audience as a whole evaluates the output as being better, worse or the same, and whether they think that the processing is better, worse or the same in terms of the software seeming less uncreative.

### *1.5.4 A Case Study in Evolutionary Art*

Evolutionary art—where software is evolved which can generate abstract art—has been much studied within Computational Creativity circles [50]. Based on actual projects which we reference, we hypothesise here the various timelines of progress that could lead from a system with barely any autonomy to one with nearly full autonomy. Figure 1.4 uses our diagrammatic approach to capture three major lines of development, with the final (hypothetical) system in box 8 representing finality, in the strong sense that the software can do very little more creatively in generating abstract art. Since features from earlier system epochs are often present in later ones, we have colour-coded individual creative acts as they are introduced, so the reader can follow their usage through the systems. If an element repeats with a slight variation (such as the removal of a bar), this is highlighted. Table 1.1 is a key to the figure, which describes the most important creative and administrative acts in the systems. Elements in the key are indexed with a dot notation: *system.process-stack.subprocess* (by number, from left to right, and top to bottom, respectively). System diagrams have repetitive elements, so that the timelines leading to its construction and what it does at run-time can be read in a stand-alone fashion.

Following the first line of development, system 1 of Fig. 1.4 represents an entry point for many evolutionary art systems: the programmer invents ($\overline{C_p}$) (or borrows) the concept formation process of crossing over sets of mathematical functions to

UNCORRECTED PROOF

Author Proof

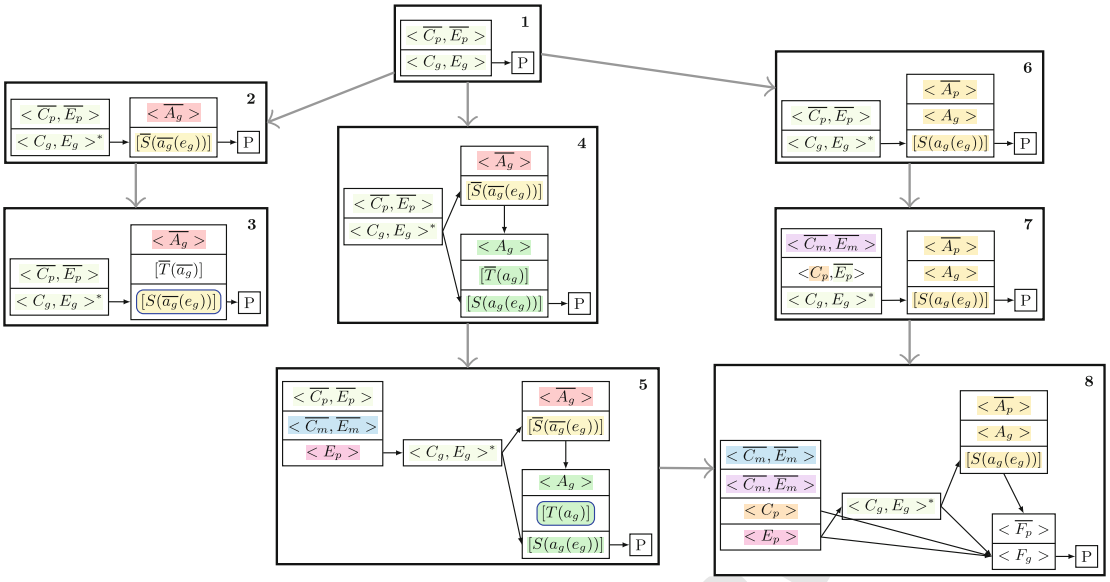

**Fig. 1.4** The progression of an evolutionary art program through eight system epochs, taken from [47]

produce offspring sets. He/she also has an idea ($\overline{E_p}$) for a *wrapper* routine which can use such a set of functions to produce images. He/she then uses the program to generate ($C_g$) a set of functions and employ the wrapper to produce ($E_g$) an image which is sent to the (P)rinter. The crossover and subsequent image generation is repeated multiple times in system 2, and then the programmer—who has invented ($\overline{A_g}$) their own aesthetic—chooses a single image to print. In system 3, as in the poetry example above, the programmer translates their aesthetic into code so the program can select images. This is a development similar to that for the NEvAr system [51].

Following the second line of development, in system 4, the programmer selects multiple images using his/her own aesthetic preferences, and these become the positives for a machine learning exercise as in [52]. This enables the automatic invention ($A_g$) of an aesthetic function, which the programmer translates by hand $\overline{T}(a_g)$ from the machine learning system into the software, as in [53], so the program can employ the aesthetic without user intervention. In system 5, more automation is added, with the programmer implementing their idea ($\overline{C_m}$) of getting the software to search for wrappers, then implementing this ($\overline{E_m}$), so that the software can invent ($E_p$) new example generation processes for the system.

Following the final line of development, in system 6, we return to aesthetic generation. Here the programmer has the idea ($\overline{A_p}$) of getting software to mathematically invent fitness functions, as we did in [54] for scene generation, using the HR system [48] together with The Painting Fool [43]. In system 7, the programmer realises ($\overline{C_m}$) that crossover is just one way to combine sets of functions, and gives ($\overline{E_m}$) the software the ability to search a space of combination methods ($C_p$). The software does this, and uses the existing wrapper to turn the functions into images. System 8 is the end of the line for the development of the software,

UNCORRECTED PROOF

Author Proof

**Table 1.1** Key to Fig. 1.4

| ID | Event | Explanation |
|---|---|---|
| 1.1.1 | $\overline{C_p}$ | The programmer invents the idea of crossing over two sets of mathematical functions to produce a new set of mathematical functions |
| 1.1.1 | $\overline{E_p}$ | The programmer implements a wrapper method that takes a set of mathematical functions and applies them to each $(x, y)$ co-ordinate in an image to produce an RGB colour |
| 1.1.2 | $C_g$ | The software generates a new set of functions by crossing over two pairs of functions |
| 1.1.2 | $E_g$ | The software applies these functions to the $(x, y)$ co-ordinates of an image, to produce a piece of abstract art |
| 2.2.1 | $\overline{A_g}$ | The programmer had in mind a particular aesthetic (symmetry) for the images |
| 2.2.2 | $\overline{S}(\overline{a_g}(e_g))$ | The programmer uses his/her aesthetic to select an image for printing |
| 3.2.2 | $\overline{T}(\overline{a_g})$ | The programmer took their aesthetic and turned it into code that can calculate a value for images |
| 3.2.3 | $S(\overline{a_g}(e_g))$ | The software applies the aesthetic to select one of a set of images produced by the software |
| 4.3.1 | $A_g$ | The software uses machine learning techniques to approximate the programmer's aesthetic |
| 4.3.2 | $\overline{T}(a_g)$ | The programmer hand-translates the learned aesthetic into code |
| 4.3.3 | $S(a_g(e_g))$ | The software applies the new aesthetic to choosing the best image from those produced |
| 5.1.2 | $\overline{C_m}$ | The programmer has the idea of getting the software to search through a space of wrapper routines |
| 5.1.2 | $\overline{E_m}$ | The programmer implements this idea |
| 5.1.3 | $E_p$ | The software invents a new wrapper |
| 5.4.2 | $T(a_g)$ | The software translates the machine-learned aesthetic itself into code |
| 6.2.1 | $\overline{A_p}$ | The programmer has the idea of getting the software to invent a mathematical fitness function |
| 6.2.2 | $A_g$ | The software invents a novel aesthetic function |
| 6.2.3 | $S(a_g(e_g))$ | The software selects the best image according this aesthetic |
| 7.1.1 | $\overline{C_m}$ | The programmer has the idea of getting the software to invent and utilise new function combination techniques, generalising crossover |
| 7.1.1 | $\overline{E_m}$ | The programmer implements this idea so that the software can invent new combination techniques |
| 7.1.2 | $C_p$ | The software invents a novel combination technique |
| 8.4.1 | $\overline{F_p}$ | The programmer has the idea of getting the software to produce a commentary on its processes and the images it produces |
| 8.4.2 | $F_g$ | The software produces a commentary about its process and product |

as it brings together all the innovations of previous systems. The software invents aesthetic functions, innovates with new concept formation methods that combine mathematical functions, and generates new wrappers which turn the functions into

UNCORRECTED PROOF

Author Proof

images. Finally, the programmer has the idea ($\overline{F_p}$) of getting the software to write commentaries, as in [41], about its processing and its results, which it does in generative act $F_g$.

Tracking how the system diagrams change can be used to estimate how audiences might evaluate the change in processing of the software, in terms of the extended creativity tripod described above. Intuitively, each system represents progress from the one preceding it, justified as follows:

**1** $\rightarrow$ **2**: $\langle C_g, E_g \rangle \rightarrow \langle C_g, E_g \rangle^*$

Simple repetition means that the software has more *skill*, and the introduction of independent user selection shouldn't change perceptions about *autonomy*.

**2** $\rightarrow$ **3**: $\overline{S} \rightarrow S$

By reducing user intervention in choosing images, the software should appear to have more *skill* and *autonomy*.

**1** $\rightarrow$ **4**: Introduction of $A_g$ and $S(a_g(e_g))$ acts

Machine learning enables the generation of novel aesthetics (albeit derived from human choices), which should increase perception of *innovation*, *appreciation* and *learning*, involving more varied creative acts.

**4** $\rightarrow$ **5**: Introduction of an $E_p$ act, $\overline{T} \rightarrow T$

Wrapper generation increases the variety of creative acts, and may increase perception of *skill* and *imagination*.

**1** $\rightarrow$ **6**: Introduction of $A_g$ and $S(a_g(e_g))$ acts

The software has more variety of creative acts, and the invention and deployment of its own aesthetic—this time, without any programmer intervention—should increase perception of *intentionality* in the software.

UNCORRECTED PROOF

Author Proof

**6** $\rightarrow$ **7**: Introduction of a $C_p$ act

Changes in the evolutionary processes should increase perceptions of *innovation* and *autonomy*.

**5, 7** $\rightarrow$ **8**: Introduction of an $F_g$ act

Framing its work should increase perceptions of *accountability* and *reflection*.

With all strands brought together, the programmer does nothing at run-time and can contribute little more at design time. The software exhibits behaviours onto which we can meaningfully project words like skill, appreciation, innovation, intentionality, reflection, accountability and learning, which should raise impressions of autonomy, and make it difficult to project uncreativity onto the software.

**Hypothesis 6** The diagrammatic formalism given above—or some extension of it—is sufficient to capture the creative acts performed in building and running any kind of generative software. Moreover, when this is used alongside audience evaluation of the artefacts produced, a formal assessment of progress in creative software development can be achieved.

## 1.6 Software as Part of a Creative Community

For each domain in which creative software operates, there is a community of people who have a stake in the notion of whether software working in that domain is perceived as creative. As described in this section, we have recently started to embed our software in such a community, for various reasons, including the study of how people react to it and to the work that it produces. These experiments will form part of a larger study of how people accept (or not) creative technologies that undertake activities which used to be the purview of people only.

### *1.6.1 Accountable Subjectivity*

Applying aesthetic judgements and expressing preferences are important kinds of activity that contribute to the perception of a person or piece of software as being creative. Aesthetics and preferences allow a creative entity, be it a person or software, to express founded judgement (even if we regard the judgement as worthless, or subjectively 'wrong') on creative artefacts, both those created by the entity itself

UNCORRECTED PROOF

Author Proof

and those created by others. It can also serve as a driving force behind future creation, allowing someone to work towards goals that they have set themselves and strengthening claims of intentionality.

Despite this, little work has been done to build systems which can generate aesthetic preferences of their own and apply them intelligently. One reason for this may be the uncomfortable clash between the subjective and the objective that so often affects research in Computational Creativity. The notion of 'optimality' in many creative domains, particularly those associated with the arts, is a contentious one and leads to much criticism of systems which attempt to quantify the quality of an artefact. The idea of having a system quantify the quality of an *opinion* on creative artefacts is equally controversial, if not more so. Similarly, in the past, the question of how to quantify the degree to which a system is creative was also a subjective and controversial task. In this case, researchers such as Ritchie found it useful to use metrics which dealt with abstract notions of creativity without directly laying out objective measures of quality for any particular artefact or medium. Ritchie's criteria are described in [55], and have been used in many evaluations of creative systems in a variety of different fields and media.

We propose here a similar set of criteria which apply to aesthetics or preferences rather than creative systems. By using abstract metrics, we can avoid talking about aesthetic measures in objective ways, while retaining a meaningful vocabulary with which to describe different kinds of aesthetics. These metrics can be used to evaluate *aesthetic comparator functions*, namely binary functions which take two examples of a type of object, and then return $-1$, 0 or 1 depending on whether the first object is preferred less, the same as, or more than the second object. Assuming we have an aesthetic function $f$, and a set of objects the function expresses a preference over, $O$, we define the following criteria which can be used to differentiate aesthetic functions from one another. Note that these metrics do not necessarily represent a linear gradient of quality—different types of aesthetic function may be desirable in different scenarios.

The first metric is *specificity*. Specificity captures the degree to which the aesthetic represents a *total order* over the set of objects $O$. If an aesthetic can offer a definite preference (that is, a nonzero result) for many of the objects, it will have a high specificity, and vice versa. High-specificity aesthetics might suggest the aesthetic is experienced or well-developed in some way, if it is able to make clear distinctions between many different artefacts.

The second metric is *transitive consistency*. This captures how self contradictory the aesthetic function is. Suppose we have three artefacts: $A$, $B$ and $C$, and our function $f$. We can write $A < B$ to indicate that $B$ is preferred to $A$. We might expect that if $A < B$ and $B < C$ then $A < C$. Transitive consistency measures what proportion of $O$ this holds for. In some scenarios, we might want a high transitive consistency, as this indicates a lack of contradictions in the preferences being expressed. However, in some scenarios, preferences can be complex and multi-objective, and it might be the case that transitivity does not hold for highly subjective opinions about artefacts produced by creative acts.

UNCORRECTED PROOF

Author Proof

The third metric is *agreement*. Instead of being expressed in terms of a single aesthetic function, agreement is expressed about two different aesthetics, which we can call $f$ and $g$. Agreement measures the proportion of the object set $O$ that $f$ and $g$ agree on. This can be *strict*, in which case $f$ and $g$ must return exactly the same value for two objects to be said to agree. Alternatively, agreement can be *non-strict*, in which case $f$ and $g$ can either return the same value, or one of the functions can return zero (no preference) to be said to agree. Informally, agreement lets us assess how closely two aesthetic functions are aligned with each other. Of course, they may be in close agreement for very different reasons—this metric simply establishes similarity in the result of the subjective judgements.

**Hypothesis 7** The perception of creativity in software which produces artefacts within a creative community will be increased if the software can exhibit subjective judgements about its own work and that of others, and defend those judgements in an accountable way. This can be seen as part of a bigger picture of software exhibiting a personality, in order to be accepted into a creative community.

### *1.6.2 A Case Study in Automatically Designed Videogames*

A *game jam* is a contest where entrants attempt to make a videogame from scratch in a short period of time, normally with the added restriction of a theme which developers must incorporate into their game somehow. Ludum Dare is one of the largest regularly occurring game jams in the game development community, taking place three times a year and garnering over 2,000 entries in December 2013, where developers were given the theme 'You Only Get One'. The ANGELINA system is an automated videogame designer developed to investigate issues surrounding Computational Creativity in a ludic and interactive context [56]. Many different versions of ANGELINA have been developed, working with various different kinds of game, technologies and user guidance. The most recent iteration, ANGELINA-5, was designed to enter game jams, by allowing it to be given just a theme in plain text as a starting point. This theme is then interpreted by ANGELINA-5 and used to influence the design of the game.

ANGELINA-5 entered Ludum Dare for the first time in December 2013, the 28th edition of the event. One of the objectives was to investigate the reactions of various groups of people to a piece of creative software entering such a contest. To gain more insight into these groups, we entered two games designed by ANGELINA-5 to Ludum Dare 28. In the first submission, *To That Sect*,[3] we included a commentary generated by ANGELINA-5 to illustrate the actions of the system, as well as multiple paragraphs describing the research behind ANGELINA-5 and identifying the game as the creation of a piece of software. In the second submission,[4] we anonymised

[3] *To That Sect* game: www.tinyurl.com/tothatsect.

[4] *Stretch Bouquet Point* game: www.tinyurl.com/stretchpoint.

UNCORRECTED PROOF

Author Proof

**Table 1.2** Percentile rankings for ANGELINA-5's two games entered into Ludum Dare 28, and its single entry to Ludum Dare 29 *(Jet Force Gemini)*

| | To That Sect | Stretch Bouquet Point | Jet Force Gemini |
|---|---|---|---|
| Overall | 36 | 29 | 23 |
| Fun | 34 | 30 | 26 |
| Audio | 73 | 43 | 74 |
| Graphics | 43 | 33 | 36 |
| Mood | 77 | 39 | 80 |
| Innovation | 64 | 33 | 59 |
| Theme | 32 | 30 | 26 |
| Humour | 48 | 59 | 51 |

Note that higher percentile rankings indicate higher achievements. There were 780 submissions in the LD28 track, and 1,004 entries in the LD29 track

ANGELINA-5's commentary to remove references to it being software-based, edited it for grammar, and added no supplementary explanation about the software, the origin of the game, or anything to connect the game with a digital author. The ratings process for Ludum Dare takes place in the 22 days following the contest, and is conducted as a peer review system, where each entrant is asked to rate and review games by other entrants. Ratings are given as marks out of five for eight categories: Audio, Graphics, Mood, Theme, Humour, Fun, Innovation and Overall. AQ2

The results for the two entries by ANGELINA-5 can be seen in Table 1.2. While we were unable to get specific vote data, we do know that 70 people rated *To That Sect*, the non-anonymised submission, while 26 people rated *Stretch Bouquet Point*.[5] While it is impossible to calculate confidence intervals for these ratings without the vote data, we can see that they differ by hundreds of positions for some categories such as Mood and Audio. We can also see a noticeable difference in the comments left by some of the reviewers underneath both submissions, in terms of their tone and attitude when dealing with each game. Many commentators indirectly criticise the anonymised game, with comments such as "You made me feel something there. Don't make me put it into words though". Other commentators made more obvious statements of criticism or praise, such as "This was a rather annoying experience" or "This game feels dreamy. The audio is intense." Only one comment included both praise and criticism. We attribute the indirect or sarcastic comments to an unwillingness to potentially criticise a person for performing poorly, even though other reviewers were less tactful. Ludum Dare is often used as a learning experience for amateur developers, and many children enter using simple game creation tools. We believe many reviewers felt uncomfortable with direct criticism for this reason.

By contrast, comments on *To That Sect* were more balanced in nature, often offering both praise and criticism in equal amounts, e.g., "Angelina seems really good at creating an atmosphere with both sound and visuals. But the game part of it seems

[5] This is due in part to ANGELINA-5's small following on the internet, which promoted the non-anonymised submission more than normal.

UNCORRECTED PROOF

Author Proof

a bit lacking still". In the description of the game, we asked people to rate it as they would any other Ludum Dare entry, hoping to dissuade people from reviewing the *concept* of ANGELINA-5 rather than the game itself. Nevertheless, many reviewers suggest that their scores were influenced by their appraisal of ANGELINA-5 as a novel system, rather than what it was capable of creating, e.g., "creating a program to create your game . . . [is] certainly not something you see every day. On that front alone, this gets a lot of points for innovation". These results suggest that reviewers were unable to separate the creator from the artefact, and were incapable of reviewing the game as if created by a person. For instance, *To That Sect* rated 282nd of 780 for Innovation. These ratings are subjective, and it is hard for us to objectively assess them. However, we do not believe there is anything particularly innovative about *To That Sect*. As such, we must attribute this high ranking to reviewers assessing the game as a product of ANGELINA-5. It seems that reviewers projected (human) innovation in the ANGELINA project onto the game it produced.

We can compare the results of ANGELINA-5's debut in Ludum Dare with the results garnered from a second entry to the game jam in April 2014, Ludum Dare 29. This time ANGELINA-5 was only entered into the game jam once, with the game *Jet Force Gemini*, created in response to the theme *Beneath The Surface*. As with the non-anonymised entry in Ludum Dare 28, *Jet Force Gemini* was entered with a commentary describing some of the decisions contributing to the design process. Table 1.2's rightmost column shows the results for *Jet Force Gemini* in contrast to the entries in Ludum Dare 28. The number of entries in Ludum Dare 29 was nearly 30 % larger than Ludum Dare 28; ANGELINA's percentile scores drop for four of seven specialised categories, and fall dramatically in the *Overall* rating.

We believe this is evidence of the relationship between the observers and ANGELINA shifting over time. While some of the comments underneath *Jet Force Gemini* indicate that the reviewer is encountering ANGELINA-5 for the first time (which is unsurprising, since the number of reviewers account for less than 1 % of total Ludum Dare entrants) others explicitly note that they are reviewing ANGELINA-5's games for a second time. One states that 'I'm sorry to say that I can't really see improvements from last time', indicating that there is either an expectation of growth on the part of the software, or an expectation that the software's author will grow the software over time. Despite many of the other comments being generally positive, the drop in ratings suggests that people perhaps feel less compelled to rate ANGELINA-5 highly for novelty value alone. Given that Ludum Dare is a community built on the idea of improving creative skills through regular practice, it is interesting to note the expectation of growth shown by some reviewers. We hypothesise that this may be a factor which is particularly important for creative individuals in assessing creativity, as opposed to other types of observer.

We can also examine reactions to particular elements of ANGELINA-5's work and compare it to critiques of similar games. One comment on *To That Sect* states "If it [had] added shooting at the statues that you must avoid and a goal how much ships you have to collect, it would have been better. It felt like playing [an] 'art-message'

UNCORRECTED PROOF

Author Proof

type of game". *LITH*[6] is a game entered into the competition by a human designer, where the player navigates a maze and collects bags of gold coins, while avoiding patrolling robots. They can escape to an exit at any stage, with their score being the amount of gold collected. While not an exact duplicate, the rules of *LITH* are very similar to those of *To That Sect*, i.e., search for as many objects of a certain type as possible, while avoiding another object, then exit. *LITH* was entered in the same track as ANGELINA-5's games, and ranked 95th Overall, 125th for Fun, and 274th for Theme. None of the comments on *LITH* reference the game's rulesets in a critical way. Notably, *LITH* ranks 259 places above *To That Sect* for Theme. This is significant, as the *LITH* designer justifies its theme in a fairly thin way, by saying simply that the player only has one opportunity to save their score (which they do by ending the game, as in *To That Sect*). The games are by no means identical: *LITH*'s level is more closed in to accentuate a feeling of claustrophobia, but the similarities are many. This analysis suggests a fundamental difference in how people evaluate a game when they have knowledge and when they have no knowledge of its designer and design process.

**Hypothesis 8** There can be both positive and negative biases at work when people consume artefacts in the knowledge that computers created them. By managing both cases in a creative community context, we can increase perception of software as being creative and enjoyment of the artefacts produced. This increase will be further fuelled if the software shows clear growth in sophistication in the field, and expresses this through its processes and products.

## 1.7 Conclusions and Future Work

Simply stated, one of the main aims of research into Computational Creativity is to one day see creative software properly embedded into society. To achieve this aim, larger sectors of society need to join the effort, including creative communities within the arts and sciences, the creative industries, technology firms, and the next generation of Artificial Intelligence researchers. Hence, we need to convince certain sets of stakeholders that creative software is no fantasy, but a potential reality that will bring benefits to society. As described above, we have studied three sets of stakeholders, namely the general public, fellow Computational Creativity researchers, and a specific community of creative people, namely videogame designers. These studies have enabled us to make concrete hypotheses related to how stakeholder communities perceive creativity in software, and how best to manage that perception in the future. Based on our immersion in the stakeholder communities mentioned, we have argued above in favour of the truth of the hypotheses, with extended discourse and argumentation given in [38, 47] amongst other papers. We believe it is now time to turn the hypotheses into experiments designed to see whether the ways in which sets of stakeholders perceive and react to creative software fit our beliefs.

Author Proof

Our first hypothesis is pitched somewhat at a meta-level, in that it proposes that different stakeholder groups see creative systems differently and their perception of software behaviour could and should be managed in a bespoke manner. We can therefore imagine an experiment where we present the processes and products from creative software to different stakeholder groups and assess their reaction to see if there is indeed a difference in how different groups react, learning from analyses of the results. Hypothesis 2 encompasses much of our philosophical position on the notion of creativity being essentially contested and secondary in nature. One can imagine restricting participants in an experiment to fairly constrained groups, and testing whether there is general (healthy) disagreement about the nature of creativity in people and software or not, and further testing whether there is more consensus about software being uncreative. To properly test Hypothesis 2, we would need to ask participants about the essential behaviours—such as intentionality, learning and reflection—they perceive to be taking place in software and see how it affects their perception of uncreativity in the system.

Our third hypothesis makes a bold statement: that blind comparison tests damage the long-term goal of embedding creative software in society, by emphasising the evident humanity gap. If this effect is true, it would be borne out by a Turing-style test where, when people are told that it was software that produced an artefact that they particularly liked, they were also asked about whether their perception of the creative act and/or the artefact had changed in light of the new knowledge. More pointed questions about the nature of any change in perception could lead to insights about how to manage the humanity gap in future projects. This would lead into an experiment to address Hypothesis 4, where computer generated artefacts were presented as re-imagined pieces with specific management of the relative lack of humanity in the generation of the artefacts. The re-imagining would specifically include commentaries and other framing information produced by the creative system. If Hypothesis 4 is correct, people would appreciate the re-imagined versions of artefacts more than those presented merely as computer-generated versions from the human oeuvre.

By proposing that random number generation detracts from an experience of a creative act, whereas more accountable unpredictability can benefit the experience, Hypothesis 5 is more specific than those preceding it. We can imagine an experiment where one set of participants are told that a particularly impressive creative act (in terms of the processing performed and/or the resulting artefacts) was because of a random event, and another set are given interesting framing information about what led—in a non-random way—to the same unpredictably good creative act. If the latter group appreciated the creative act and its results more than the former group, the truth of the hypothesis would be upheld.

We have already started work on testing Hypothesis 6, i.e., that the formalism presented in [47], can capture notions of progress when building creative systems. That is, we have used the formalism to capture abstracted timelines leading to the building of certain creative systems, and timelines where that software operates and produces artefacts of value. However, to convince the Computational Creativity researcher stakeholders of the value of the formalism, we need to work with them to capture the essence of their approaches to implementing and operating creative

Author Proof

software. Moreover, our audience evaluation model is far from complete. We plan to employ the criteria specified in [55], for more fine-grained evaluations of the quality, novelty and typicality of artefacts. We will also import audience reflection evaluation schemes from the IDEA descriptive model, e.g., change in well-being, cognitive effort and emotional responses such as surprise and amusement.

The final two hypotheses we present above relate to communities of creative people into which creative software is implanted. To address Hypothesis 7, we will need to implement software behaviours which can meaningfully be described as subjective, and we plan to do so with the ANGELINA videogame generation system, and others such as The Painting Fool automated artist. With such systems, we can experiment to see whether members of the creative community are more impressed by subjective software or not. Such an experiment could be simultaneously used to address the final hypothesis, with knowledge of the computational origins of artefacts systematically withheld in order to see whether positive or negative biases hold in different creative communities. Similarly, experiments where participants are told about the intellectual growth of a system could be carried out, to see if this influences their impression of the software. An analysis of the findings from such experiments could help pave the way for software to be full members of these kinds of communities.

Looking at the three stakeholder groups studied here, we see some emerging generalities. In particular, looking at behaviours where systems exhibit subjectivity and intentionality, it seems clear that in all three groups, *personality modelling* in software has the potential to increase the impression that people have of what software does and, in turn, what it produces. This is part of a new understanding of creative acts as being potentially interesting, even dramatic, episodes of activity which can amuse and engage people, rather than a means to the end of producing an artefact of value. This is in contrast with the traditional idea that the value of the output from software can increase people's appreciation of the creativity it exhibits. While the traditional view is often correct, it is not the only model of managing perceptions of creativity in software.

The hypotheses presented here are only a subset of those which should be proposed and addressed in the future of Computational Creativity research. Not addressing such issues would be a mistake, as stakeholder perception of creativity in software will in part dictate the number of researchers and businesses coming into the field. Done badly, handling of stakeholder perceptions could stall the forward progress achieved towards embedding creative software in society. As a recent controversial example, online retailer Amazon briefly sold T-shirts with slogans such as *"Keep Calm and Rape a Lot"* [57]. The T-shirt company responsible posted an apology on its website, and insisted that the offending articles were "automatically generated using a scripted computer process running against hundreds of thousands of dictionary words". This may be the first example of computer generated artefacts causing such offence and a company—while taking responsibility—blaming generative software for poor quality artefacts, while tacitly acknowledging that the software had taken on unsupervised creative responsibilities in their workplace.

Author Proof

Situations where software is employed independently for creative purposes in commerce and elsewhere are likely to become more commonplace in the future. As a more positive example, IBM researchers have recently undertaken research to explore the commercial potential of Computational Creativity [58], with particular emphasis on culinary creativity [59, 60]. Creative software will make great inventions and make terrible mistakes in the future, and this will lead to a re-evaluation of humanity as being the centre of the creativity universe. Managing stakeholder perceptions of creativity in software will be paramount in making this transition as smooth and as fruitful for society as possible.

**Acknowledgments** Some of the work presented here was originally explored in [38, 47], and we are very grateful to the organisers of the AISB 2014 symposium on Computing and Philosophy, and the organisers of the 2014 International Conference on Computational Creativity. We wish to thank the many researchers with whom we have discussed the views presented in this chapter, especially our colleagues in the Computational Creativity group at Goldsmiths College. This research has been funded by EPSRC grants EP/L00206X and EP/J004049, and with the financial support of the Future and Emerging Technologies (FET) programme within the Seventh Framework Programme for Research of the European Commission, under FET-Open Grant numbers: 611553 (COINVENT) and 611560 (WHIM).

# Building the Peeragogy Accelerator

Joseph Corneli, Dorota Marciniak, Charles Jeffrey Danoff, Charlotte Pierce, Paola Ricaurte, Jan Herder, Suz Burroughs, George Brett, John Graves

**Abstract**

The Peeragogy Project facilitates the reflective practice of peer learning and peer production. We are building living projects that continuously evolve, and we have come together with several of our own projects to build a space for mutual aid. In short, we are building a peer produced Peeragogy Accelerator. We present the background and operating principles of the Accelerator, and describe some of the Accelerated projects: SOLE out of the Box, which aims to build a self-sufficient distributed makerspace; PlanetMath.org, an online mathematics community that will soon run its first peeragogical Calculus course; and *Managing Innovation and Change*, a semester-long academic course on building startups that is using peeragogy concepts. The Peeragogy Accelerator works "transversally" across these and other projects, supporting both peer-to-peer and Project-to-Project collaboration. We are actively seeking to involve others from the OER world.

**Keywords**: peer learning, peer production, peeragogy

## Introduction

The Peeragogy Project combines reflection and practice in support of peer learning and peer production. An emphasis on both *doing* and *understanding how* gives us a distinct perspective. The project synthesizes communication and contributions from globally distributed members. We are teachers, students, and researchers; editors, publishers, and writers; activists, makers, and (co)designers; but inside the project, there are no "teachers" or "students." Each contributor brings their own vision and values, and we all learn. When we come temporally together, the "Aha!" moments come thick and fast. In the process, differing viewpoints emerge, but we find agreement to be less important than co-creation of a space for learning and productive work. We emphasize the central importance of an environment of mutual respect and enjoyment. This approach has profound implications for the way we do things, and what we choose to work on.

We have always preferred to *drink our own champagne* – but new wine needs new bottles. Having co-produced the *Peeragogy Handbook* (Rheingold *et al.*, 2014) and learned a lot in the process, we are now building a peer produced Peeragogy Accelerator – a living resource for those seeking assistance with applying the reflective practice of peer learning and peer production in their own projects. A brief "Who, What, When, Where, Why, and How" exercise from the *Peeragogy Handbook* plays the role of *S. cerevisiae* for our new brew.

1. **Who: Fluxuating roles.** Some of the people involved in the Accelerator were involved as co-authors of the *Handbook*. Others joined the Accelerator driven by interests in topics such as open source, open science, open education, and peer-to-peer, informal education. We have different visions: it's *not about consensus.*

2. **What: Nature of the project**. The Peeragogy Project has built peeragogy as "something for us" rather than "something for them." The Accelerator will help make the *Handbook* useful for new projects: we improve our methods as we go.

3. **When: Time management.** We hold regular weekly meetings on Mondays at 6PM UTC, with break-out meetings and asynchronous collaboration as needed. We publish the *Handbook* annually on January 1st (Public Domain Day). The Accelerator will formally induct the first "class" in June.

4. **Where: Journey vs destination.** We value the process more than the product. The Accelerator aims to be a meta project, *a place for people to bring their own projects* and receive support from each other.

5. **Why: Putting peeragogy into practice.** "Success" in our own projects will provide case study material to *improve* the Handbook.

6. **How: Linearity vs Messiness.** Our "How to Get Involved" page contains a list of tools and activities. Keeping in mind the importance of polycentric leadership in the Peeragogy Project, people should feel free to innovate. Our general operating principles are below.

We are different from other incubator and accelerator projects in that we are entirely peer produced. Instead of signing away a percentage of future profits or some of us paying tuition to others for mentoring services, contributors "p(l)ay" together, with volunteer effort in the present.

## Operating principles for the Peeragogy Accelerator

### A living project

1. We build *living projects* that can continuously evolve.

2. We measure our progress by things *actually done*, and the process by which they are done.

3. Although we can, and do, adopt concrete goals (for example, to write a book or collaborate on this paper), we do not expect our work to be *final*. Every contribution leads to improvement.

4. In the Accelerator, people can *branch, fork and merge* other projects, as they might with source code in a Git repository. Each version or thread has its own life.

**Peeragogy Labs: try new things, and discover what works!**

5. Everyone chooses their own meaningful contributions – and each may (optionally) have their own business models in mind.

6. We use non-restrictive licenses, and each member can re-package Peeragogy in their own way if they want to. For example, a fee-based peeragogy workshop and pay-to-download Peeragogy notebooks are entirely compatible with what we're doing with the all-volunteer Accelerator and the co-created CC-Zero *Peeragogy Handbook*.

7. Although we released our *Handbook* into the Public Domain, we do like to know who made things with it, how they made it, and why. We manage this information in an extra-legal way. Indeed, we cannot enforce informed re-use, since there is no uniform way to express this sort of information. We strive for good ways to express and implement sharing at this level, building towards a *creativity commons,* above and beyond the legal instruments of the Creative Commons.

**Measure of success → values**

8. Instead of measuring "success" via downloads or sales, we ask:

   *What have we actually done? How was it done? What values did we evolve in ourselves? What did we learn to support? What values did we share with the world? How did we experientially support something for someone? What did we change in the world in the process? How did we improve our own well-being? How did we evolve as a group?*

9. Accordingly, in general we measure in a qualitative way, rather than a quantitative way. We can certainly do quantitative studies in order to help understand how things work, but this understanding does not come from measuring isolated and arbitrary scalar values like "participation".

**Creating contexts**

10. Ask "What's the next step?" rather than "What's the ultimate goal?" If we are going in a given direction, it does not mean we need to go forever in that direction. An important part of peeragogy is making it clear how people can become meaningfully involved with what you are doing.

11. For example, when the Peeragogy Project was just about writing the *Handbook*, that was the one thing people could get involved with. In the Accelerator, you do not need to be a co-author to become involved – you need only share an idea for a peer learning or peer production project. And we can always strive to go further in this way.

# Background

Peer production in education is not new. Booker T. Washington's students and faculty learned agriculture, architecture and construction as they built the Tuskegee Institute, producing an educational institution that thrives today, more than a century after Washington (1901) wrote these words:

> *I was determined to have the students do not only the agricultural and domestic work, but to have them erect their own buildings.* […] *Not a few times, when a new student has been led into the temptation of marring the looks of some building by lead pencil marks or by the cuts of a jack-knife, I have heard an old student remind him: "Don't do that. That is our building. I helped put it up."*

Information technology amplifies opportunities for peer-to-peer collaboration. Following Benkler's (2002) seminal work, Shaw & Hill (2014) describe an important new way of working that has developed considerably over the last decade:

> *Commons-based peer production – the distributed creation of freely accessible information resources through the mass aggregation of many small contributions – represents a model of collective action and public goods production that integrates the use of digital communication networks and information technologies.*

These authors make it clear that peer production is not a panacea, but it is also not the only relevant recent innovation. Design patterns, invented by Christopher Alexander in the field of architecture in the 1970s (Alexander, Ishikawa, and Silverstein, 1977), and spreading from there to to software (Gamma *et al.*, 1994; Gabriel, 1996), and later, to other fields, provide a way to communicate and share effective practice. "Pedagogical Patterns" is a network that came together to develop and provide easily transferable strategies showing how best to bestow knowledge. The *Peeragogy Handbook* includes our own catalog of design patterns that explore how peers can produce knowledge together, while building a shared "how-to".

When we think of *open practice*, following Asger Jorn (1994 [1960]), we think of an exploration of the "polyvalence of the unique". Some of the groundwork for peeragogy was developed when two of us did this at P2PU, signing up for each other's courses and critically examining the institution as a whole as the term progressed (Corneli & Danoff, 2011).

Peer learning is not something to "provide" (Boud & Lee, 2005), but something to do – and, of course, something to study – but we strongly prefer to do this in the mode of studying *with*. As with the Las Endredadas network of Latin American activists, the Infusion Project built by creative professionals, and the *Open Advice* book created by some of the leading figures in open source software, we are building our own meta-project to pursue this goal.

# Works in Progress in the Accelerator

The current list of Accelerated projects is as follows:

- SOLE Out of the Box,
- PlanetMath.org,
- Mr. Danoff's Teaching Laboratory,
- "PeerPubU", a project by the Independent Publishers of New England (IPNE),
- Managing Innovation and Change, a course at the Bill Greehey School of Business, St Mary's University in San Antonio,
- The Peeragogy Accelerator itself
- … and enrollment for this round is open until June 1st, 2014.

In the limited space, we will not be able to describe all of these projects in depth, so we focus on a few examples. More information can be found on the landing page for the Peeragogy Accelerator group on the Commons Abundance Network.

**SOLE out of the Box**

This project is building a strategy to create a self-sufficient, Self Organizing Learning Environment (SOLE) (Mitra & Dangwal, 2010), in the form of a distributed 'makerspace.' We want to tackle two interrelated global problems: access to education and access to meaningful employment. The innovation would be to build a system that sustains the development of self-directed learners, through a network of living centers, which have correct complexity to evolve sustainably and abundantly. These "Learner Makerspaces" are a distributed network of micro universities. They are considered social businesses, because their purpose is to provide employment while each participant learns. A core group of organizers initiate the makerspace, building initial working models and an "Owners Manual". Investors contribute to capital and infrastructure. Wages and operating expenses are generated from the activity of the makerspace. The project's initial income plan is to abundantly produce food through the science of aquaponics, using Arduino monitors. This leads to a STEAM-focused project-based makerspace and will provide the foundation for a 'Cyber Cafe' to initiate the SOLE.

**PlanetMath.org**

Following on Joseph Corneli's (2014) thesis work, in which PlanetMath users helped develop new design patterns that could be used to improve PlanetMath as a learning platform, there were many high-level and low-level programming changes to make, including development work to improve PlanetMath's presentation of books. We plan to import mathematics books from Project Gutenberg and other sources, and apply optical character recognition (OCR) techniques to retrodigitize more math books ourselves. One of the books we have already imported is an early 20th Century Calculus textbook (Davis & Brenke, 1912), which includes some rather quaint examples, but which otherwise looks quite contemporary when rendered in MathML. We are planning an online peeragogical Calculus course, whose syllabus will feature this text and other resources from around the 'net. This course is built around design patterns – including patterns to deal with the common points of confusion associated with Calculus.

**Managing Innovation and Change**

This course on *Managing Innovation and Change* is targeted for Junior and Senior high performing undergraduates at the Bill Greehey School of Business at St. Mary's University in San Antonio. The course integrates peeragogical concepts in an "amortized" manner. Students have increasing autonomy as the course progresses.

The course is structured with a flipped classroom format and labs or workshops in the first half of the semester and a real world practicum project graded on execution and impact in the second half. Assessment is based on a student-generated peer assessment rubric. Accelerator members have offered peeragogical support, discussing the course concepts and design in a weekly online PreK-16 practitioners forum.

Our objective in this course is to fill the current educational model gaps, by teaching collaboration skills and integrated systems thinking. We are frequently reminded by students that we address skills and concepts not covered by any other courses in the school such as teaming, social media marketing, cloud collaboration, web site editing, and strategies for coping with high performance contexts.

The change in expectations and context has been disorienting for students, as is the online learning portion for the course. The technology presents one learning curve, and the human aspects of the digital context are another. We opted to strictly require online participation. We frequently read in weekly journals that we are opening up experiences of things that students feel they should be getting throughout their degree program.

**Auto-Acceleration of the Peeragogy Accelerator**

Peeragogy is large and diffuse, but in order to facilitate progress at a rapid pace, we have convened a small working group of persons with relatively concrete goals. The Accelerator is supported by peeragogy mavens, but, critically, it is also open to newcomers who are trying to understand and integrate peeragogy processes and metaphors into their context. Working together, we all learn.

## Discussion

Building on our peer-to-peer experiences working together on the *Peeragogy Handbook* we have re-organized ourselves for Project-to-Project collaboration. Our methods include "Hive editing" document meetings (working as a group using recorded Hangouts on Air together with Google Docs or Etherpads), and "Wrapping" our works-in-progress with summaries for a wider contributing public. It is worth emphasizing, again, that we all have our own working methods and preferences, and that we do not require everyone to do things the same way. Our attention options for our meetings include: participating in the live hangout, watching the video stream and joining asynchronously later via the Peeragogy in Action Google+ community. When writing collaboratively, some like to edit, others to comment. We learn from each other's approaches and values, and create new values together, e.g., observing that it is very useful, when one person is talking during a meeting, for another to type a transcript of what that person is saying. We encourage contributing projects to carefully specify their own operations and the qualitative outcomes that they are seeking through Acceleration.

**Limitations and Future Work**

We cannot currently point to a case study that demonstrates “X% passing without peeragogy, and Y% passing with peeragogy,” or anything of this sort. We may be experiencing a “Peeragogy Island” effect: we are quite happy with what we are doing, but it does not always resonate with outsiders. Even so, examples like *Managing Innovation and Change* show that peeragogy can be not only compatible, but helpful at numerous points within a (relatively) mainstream course.

How can we escape from Peeragogy Island? Involving others from the OER world, as we are doing in our workshop for OER14, may be very helpful for this. We have improved on our previous outreach activities by providing more concrete ways for people to get involved. Many Future Work ideas are recorded as “What’s Next” sections in the patterns in our pattern catalog – a “living” design for a living project.

**Summary of our contributions**

Peer learning and peer production benefit from participatory engagement at every level. Building novel systems for collaboration that are themselves peer produced offers users rich opportunities for meaningful engagement. The *Peeragogy Handbook*, including the latest version of our design pattern catalog, is a peer produced Open Educational Resource, available under the terms of the Creative Commons Zero license: it can be freely adapted. We continue to improve and refine the *Handbook* through our work in the Peeragogy Accelerator.

# NNexus Reloaded

Deyan Ginev[1] and Joseph Corneli[2]

[1] Computer Science, Jacobs University Bremen, Germany
[2] Knowledge Media Institute, The Open University, UK

**Abstract.** Interlinking knowledge is one of the cornerstones of online collaboration. While wiki systems typically rely on links supplied by authors, in the early 2000s the mathematics encyclopedia at PlanetMath.org introduced a feature that provides automatic linking for previously defined concepts. The NNexus software suite was developed to support the necessary subtasks of concept indexing, concept discovery and link-annotation. In this paper, we describe our recent reimplementation and revisioning of the NNexus system.

## 1 NNexus 1.0 – Introduction

PlanetMath.org is a mathematics digital library, built "the commons-based peer production way" [Kro03]. Like Wikipedia, which launched the same year, PlanetMath has been created by volunteer contributors from around the world. However, unlike Wikipedia, PlanetMath focuses solely on mathematics. Since its launch, it has used custom software both to support the display of mathematical expressions, and to facilitate the integration of new user-contributed content. One of the features designed to assist in content integration was an *autolinking service*. This service allowed authors to write without concerning themselves with wiki-style links to technical concepts that had already been added to the corpus. Instead, these links would be added automatically – and links would be recalculated and adjusted automatically as the encyclopedia grew, using a sophisticated caching and expiry system. The system provided an example of named entity recognition [NS07], where the entities to identify in submitted text are article titles, the names of terms defined in the articles, and any known synonyms. The process of adding links to named entities in text has come to be known as "wikification" [Rat+11].

In 2006, NNexus 1.0 began the process of decoupling autolinking from PlanetMath, and provided integration with other corpora (Wikipedia, Mathworld) on a demonstration basis [GKX06], an effort that has matured with the current release.

## 2 NNexus 2.0 – Reload, Refresh, Refactor

The primary goal of our rebuild was to decouple fully from the old Noosphere system on PlanetMath.org. A strong contributing motivation was that Noosphere was in the process of being deprecated on PlanetMath and replaced by

the new Planetary system [CD12]. The new NNexus works with Planetary, but also functions in a stand-alone fashion, and is published as a software library on the Comprehensive Perl Archive Network (CPAN).[3] It has been refactored to operate either as a web service,[4] or programmatically via an API. NNexus accepts arbitrary HTML input and performs concept discovery against its concept index, followed by a serialization of the mined data, either as stand-off metadata or by in-place embedding.

Concept indexing is performed by NNexus' built-in web crawler. It is based on a plugin architecture. Every indexed web resource requires its own indexer class, which contains the custom rules for detecting the concept definitions in the page. For example, PlanetMath's key terms are found in RDFa metadata that has been deposited in the encyclopedia pages, whereas the Digital Library of Mathematical Functions lists its defined concepts in its index as bold-anchored elements.

The current NNexus release ships with a database that integrates the concepts from seven web resources for mathematical concepts. These include the three best-known web resources for mathematics – Wolfram's MathWorld; PlanetMath.org; and Wikipedia – as well as Springer's Encyclopedia of Mathematics; the Digital Library of Mathematical Functions (DLMF); the nLab (which focuses on category theory); and the recently created MathHub.info.

At the time of writing, the NNexus index contains just under 50,000 unique concepts in its index. With the introduction of client-side tools for embedding NNexus [Gin13], we can also report successful auto-linking in third-party platforms such as arXiv.org and Zentralblatt MATH.

## 3 Concept Discovery

The NNexus implementations to date have only scratched the surface of the knowledge discovery problem. NNexus performs longest-token matching, aided by classic preprocessing techniques (stopword lists, morphological normalization) to discover all possible concept candidates. Concepts are considered discovered if there is an exact match between the linguistically normalized input document and the identically normalized concept index. When a concept $A$ is a substring of a concept $B$, since they both match at the same starting point of the input, preference is given to the longer string $B$. To demonstrate, take $A$ to be "fundamental groupoid" and $B$ to be "fundamental groupoid functor".

This simplistic approach leads to false positive hits, for instance, in words that have multiple part-of-speech uses or words that have both technical and everyday meanings. Accordingly, each of the following examples becomes a candidate for linking, even though the words in the right-hand column are not being used in a technical sense.

[3] Run **cpan NNexus** to install the software locally.

[4] A demonstration instance is available at `http://nnexus.mathweb.org`. Sending an HTML snippet as the body of a POST request will return the link-annotated snippet back, embedded in a thin JSON wrapper.

"*Let G be a* ***group***" "***group*** *the numbers in rows*"
"***chain*** *in a graph*" "***chain*** *made of steel*"
"***permanent*** *of a matrix*" "*using a* ***permanent*** *marker*"

This particular phenomenon is less observable as the length of the concept grows, both because longer words are less frequently overloaded and because multi-word concepts rarely have non-technical meanings. Inversely, the problem is particularly challenging in concepts with short single-word names.

Another challenge is disambiguating between overloaded concept names, used differently in different scientific areas. To address that, NNexus does not immediately return all of the named entities it discovers. Instead, it first uses a clustering algorithm, based on a distance metric between the classes of the MSC [Ame09] categorization scheme, which determines a kernel of closely related concepts. We have observed our distance metric is effective in separating concepts from typically disjoint subfields of science, but less successful in making fine-grained distinctions in subfields that tend to have a lot of mutual connections. For example, "entanglement" is a concept both in quantum mechanics and graph theory. NNexus is able to tell which meaning is intended by contextually clustering with the rest of the discovered concepts. However, generic concepts such as "equivalence" tend to be redefined in closely related subfields, and NNexus cannot tell these apart.

In addition to these technical limitations, NNexus is limited by the quality of the metadata provided by its indexed sources. For example, as pointed out by one of the reviewers of this paper, PlanetMath currently has no article on "classical logic", and links to this term are currently being directed to PlanetMath's article on quantum logic. This looked like a rather strange error until we realized that the quantum logic article includes a definition of the term "classical logic", in contravention of the "one main concept per article" norm.

## 4 NNexus 3.0 Revolution – an Outlook

Auto-linking continues to be a useful tool around PlanetMath. For instance, Planetary added support for contributing problems and problem sets, and technical terms in problems are linked to definitions drawn from the encyclopedia. We plan to add a PlanetMath feature where, given a contributed piece of text, a small "course packet" of preliminaries would be built on the fly, created out of auto-linked encyclopedia articles. Thanks to the metadata in the links provided by NNexus, we will be able to consider both "incoming" and "outgoing" links – this means we can discover applications of a concept as well as simpler concepts.

Some other efforts that we plan to explore include autolinking in math blogs, such as the blogs indexed on `http://mathblogging.org/`. NNexus could build a "term cloud" of technical terms from across the math blogosphere, providing a useful access method that parallels the familiar tag cloud.

The main challenge ahead is to solve the problem of reliable concept discovery. The immediate goal is to achieve reliable disambiguation of overloaded concept words (such as "set" or "group"), possibly by employing the help of a

part-of-speech tagger. A complementary idea is to improve precision by augmenting longest-token matching with weights derived by statistical term-likelihood analysis. As statistical term-likelihood methods do not depend on an a priori fixed lexicon, they could also be used to detect concepts that are not yet included in the index. That would allow us to enable another desirable feature – the automatic creation of dangling links (similar to Wikipedia's "red links").

Deeper scrutiny of mathematical formulas and terms will allow us to link occurrences of math constants in MathML, both globally, for symbols like the reduced Planck constant $\hbar$, and locally, following the annotation of the corresponding natural language term, such as "Assume a cyclic group $\mathbb{Z}_{mn}$ ...".

# Assessing Progress in Building Autonomously Creative Systems

**Simon Colton*, Alison Pease†, Joseph Corneli*, Michael Cook* and Teresa Llano***
*Computational Creativity Group, Department of Computing, Goldsmiths, University of London, UK
†School of Computing, University of Dundee, UK
ccg.doc.gold.ac.uk

**Abstract**

Determining conclusively whether a new version of software creatively exceeds a previous version or a third party system is difficult, yet very important for scientific approaches in Computational Creativity research. We argue that software product and process need to be assessed simultaneously in assessing progress, and we introduce a diagrammatic formalism which exposes various timelines of creative acts in the construction and execution of successive versions of artefact-generating software. The formalism enables estimations of progress or regress from system to system by comparing their diagrams and assessing changes in quality, quantity and variety of creative acts undertaken; audience perception of behaviours; and the quality of artefacts produced. We present a case study in the building of evolutionary art systems, and we use the formalism to highlight various issues in measuring progress in the building of creative systems.

## Introduction

Creativity, we believe, relates to a perception that others have of certain behaviours exhibited by some person or system, rather than an inherent property of people or software: in this sense it is a secondary quality. Moreover, we believe that, just as the endless debates about "is it art?" fuel innovation in the arts, the endless debates about "is it creative?" are a force for good: they drive forward creative practices and Computational Creativity research. A longer discussion of this philosophical position is given in (Colton et al. 2014), and an exposition of creativity as being *essentially contested* (Gallie 1956) is given in (Jordanous 2012).

In such a context of energetic and subjective debate about creativity, it has been difficult to derive systematic approaches to assessing progress in the building of software for creative purposes. One main issue has been the cross-purposes of the creativity project(s) for which software is developed. A useful analogy with the notions of weak and strong AI has arisen recently in Computational Creativity research. Focusing on software which generates artefacts such as poems, paintings or games, we can say that *weak Computational Creativity* objectives emphasise the production of increasingly higher valued artefacts, whereas *strong Computational Creativity* objectives emphasise increasing the perception of creativity people have of the system. This is similar to the distinction put forward in (al-Rifaie and Bishop 2012). In many projects, there are both strong and weak objectives, and often they are not complementary. For instance, increasing autonomy in software may lead simultaneously to higher perception of creativity and lower value artefacts being produced. This is described as the *latent heat* problem in (Colton and Wiggins 2012), and is analogous to U-shaped learning, where to get better, we first have to get worse.

The objectives for a project usually influence the assessment methods employed. In particular, to assess progress with respect to weak objectives, it makes sense to evaluate the quality of the artefacts produced. In contrast, for strong objectives, it makes more sense to assess what software actually does and how and why people perceive it as creative or not. To this end, in (Colton, Pease, and Charnley 2011) we introduced the FACE descriptive model to formalise descriptions of the creative acts undertaken by software, and the IDEA model to formalise the impact those creative acts might have on people. Subsequent attempts to use these models to describe particular systems have highlighted another major issue: the assignment of programmer/software ownership of creative acts. Along with other issues in applying it to describe systems, we have found the FACE model to be inadequate for fully capturing the interplay of creative acts between programmer and program in this respect.

We describe here the next stage of our formalism for capturing notions of progress in building creative systems. We first provide a potted history of how progress has been evaluated in Computational Creativity research, and lay out some intuitive notions of progress. Given our philosophical and practical standpoints, we place less emphasis on asking whether artefacts are 'better' than previously. We also avoid direct questions about 'creativity' in computational systems. Instead, we integrate (i) aspects of the FACE and IDEA models (ii) objective measures of quality, quantity and variety of creative acts and (iii) audience perceptions of software behaviour and quality of output. We present a two-stage method for estimating whether obvious or potential progress or regress has occurred when building a new system. This involves diagrammatically capturing various timelines in the building and execution of a system, then comparing diagrams. We use the method to describe progress of an evolutionary art system, leading to a general discussion about how the approach could be used in practice. We conclude by describing future directions for this formalism.

## Background in Assessing Creative Progress

The assessment of progress in building creative systems has been a bespoke and multi-faceted endeavour, driven by various, often opposing objectives ranging from understanding human creativity to practical generation of artefacts to the raising of philosophical questions. The majority of practical researchers who engineer and test software joined the Computational Creativity field with objectives in the weak sense of getting software to produce quality artefacts. Hence the first way in which progress was assessed was Boolean: if software reliably produces artefacts of a particular type, then this is progress over software which was unreliable or unable to produce artefacts of the required form.

In such a context, Turing-style discrimination tests indicated a particularly strong milestone: if certain artefacts – usually hand-selected – looked/sounded so like human-authored counterparts that observers couldn't tell the difference, progress had certainly been made. This approach was pioneered by (Pearce and Wiggins 2001) who were one of the first to emphasise the importance and role of evaluation in Computational Creativity, and to propose a concrete way of applying Popperian falsificationism. However, despite them urging caution at depending on the discrimination test to evaluate creativity, direct comparison of human produced and computer generated artefacts has frequently been used to assess progress. We further criticised such Turing-style tests in Computational Creativity, for, among other reasons, encouraging naïvety in software and the generation of pastiches (Pease and Colton 2012). Moreover, we question whether this methodology, while beneficial for short-term scientific progress, is actually detrimental to the longer-term goal of embedding creative software in society (Colton et al. 2014). The work of (Ritchie 2007) was an important step away from simplistic discrimination tests, establishing an approach to assessing the value of artefacts according to their *novelty*, *typicality*, and *quality* within a genre. A number of practitioners have used this approach to compare and contrast their systems, e.g., (Pereira et al. 2005).

As the field matured, attention moved from *mere generation* to programs able to assess, critique and select from their output. Often searching large spaces, software was required to find the best artefacts using mathematically derived or machine-learned aesthetic/utilitarian calculations (Wiggins 2006). If a later version of software – with more sophisticated internal assessment techniques – was able to produce higher yields of higher quality artefacts when assessed externally, then clear progress had been made.

Audience perceptions of software became a focus, as the field further matured. Jordanous used methods from linguistics to determine how people are using the word 'creativity', and which other concepts are associated with it, and then used crowdsourcing techniques to evaluate a creative system in terms of the associated concepts (Jordanous 2012). As a complement to Jordanous's work in which she tried to *capture* society's perception of creativity, researchers began investigating ways to *influence* people's perception of creativity in software. Software assessing its own work made it *appear* more intelligent, and *seem* more creative. This led to the engineering of software that *framed* its processes and outputs by producing titles, commentaries and other material. (Charnley, Pease, and Colton 2012) propose that this may increase perception of creativity, and audiences would possibly appreciate the artefacts produced more. Studying audience perceptions of creativity in software opened many research avenues, but raised an important problem: that the original product-based assessment methods no longer capture all intuitions of what constitutes progress in the field.

From a strong perspective, some researchers, including ourselves, are not content to accept the underlying assumption of product-based evaluation methods: if better artefacts are produced, the software must have been improved, hence people will project higher perceptions of creativity onto the software and progress will have been made. As mentioned previously, the main problem here is that increasing autonomy – which must happen if strong objectives are to be met – can decrease artefact value. Conversely, when the objectives of a project are weak, it is perfectly natural to decrease software autonomy to produce artefacts of presentation quality, especially when a concert/exhibition is looming, but this is unlikely to increase any perceptions of creativity.

Concentrating on understanding perceptions of software creativity by the general public, we introduced the *creativity tripod* in (Colton 2008b) as three types of behaviours which were necessary (but not necessarily sufficient) for software to avoid being labelled as 'uncreative'. We proposed that people are influenced by their understanding of what software does when assessing its output. We argue that it is easy to ascribe uncreativity to software which is not simultaneously seen as *skillful*, *appreciative* and *imaginative*.

Focusing on assessment of progress by peers, we introduced the FACE and IDEA descriptive models in (Colton, Pease, and Charnley 2011) and (Pease and Colton 2011). The FACE model categorises generative acts by software into those at (g)round level, during which base objects are produced, and (p)rocess level, during which methods for generating base objects are produced. These levels are subdivided by the types of objects/processes they produce: $F_g$ denotes a generative act producing some framing information, $A_g$ denotes an act producing an aesthetic measure, $C_g$ denotes an act producing a concept and $E_g$ denotes an act producing an example of a concept. Generative acts producing new processes are defined accordingly as $F_p$, $A_p$, $C_p$ and $E_p$. Tuples of generative acts are compiled as *creative acts*, and various calculations and recommendations are suggested in the model with which to compare creative systems. We developed the IDEA model so that creative acts and any impact they might have could be properly separated. We defined various stages of software development and used an ideal audience notion, where people are able to quantify changes in well-being and the cognitive work required to appreciate a creative act and the resulting artefact/process.

We have arrived at a very observer-centric situation in the assessment of progress towards creative systems, in which progress can only be measured using feedback from independent observers about both the quality of artefacts produced and their perceptions of creativity in the software. Unfortunately, the majority of researchers develop software using only themselves as an evaluator, because observer-

based models are too time-consuming to use on a day-to-day progress. These informal in-house evaluation techniques generally do not capture the global aims of the research project, or of the field (e.g. producing culturally important artefacts and/or convincing people that software is acting in a creative fashion). In many cases, systems are presented as feats of engineering, with little or no evaluation at all (Jordanous 2012). We argue that assessing *progress* is inherently a process-based problem. We focus here on modeling diachronic change across multiple levels.

## A Formal Assessment of Progress

We combine the most useful aspects of the IDEA and FACE models, an enhanced creativity tripod, and aspects of assessing artefact value into a diagrammatic formalism for evaluating progress in the building of creative systems. We focus on the creative acts that software performs, the artefacts it produces and the way in which audiences perceive it and consume its output. We simplify by assuming a development model where a single person or team develops the software, with various major points where the program is sufficiently different for comparisons with previous versions. We aim for the new formalism to be used on a daily basis without audience evaluations, to determine short term progress, but for it also to enable fuller audience-level evaluations at the major development points. We also aim for the formalism to help determine progress in projects where there are both weak and strong objectives. We found that the original FACE model didn't enable us to properly express the process of building and executing generative software. Hence another consideration for our new model is that it can capture various timelines both in the development and the running of software in such a way that it is obvious where the programmer contributed creatively and where the software did likewise.

With the above aims in mind, we envisage a scenario where we are comparing two versions of creative software $v1$ and $v2$. At the highest level, we split the assessment method into a two stage process as follows:

---

1. Diagrams are drawn for both $v1$ and $v2$ which capture the interplay of programmer and program behaviours as timelines during both the development phase and the runtime execution of both versions of the software.

2. The diagrams for $v1$ and $v2$ are compared by an audience to determine if the second system represents progress over the first in terms of process. Similarly, the output from $v1$ and $v2$ is compared, to see if progress has been made.

---

### Stage 1: Diagrammatic Capture of Timelines

Taking a realistic but abstracted view of generative software development and deployment, we identify four types of timeline. Firstly, generative programs are developed in **system epochs**, with new versions being regularly signed off. Secondly, each process a program undertakes will have been implemented during a **development period** where creative acts by programmer and program have interplayed.

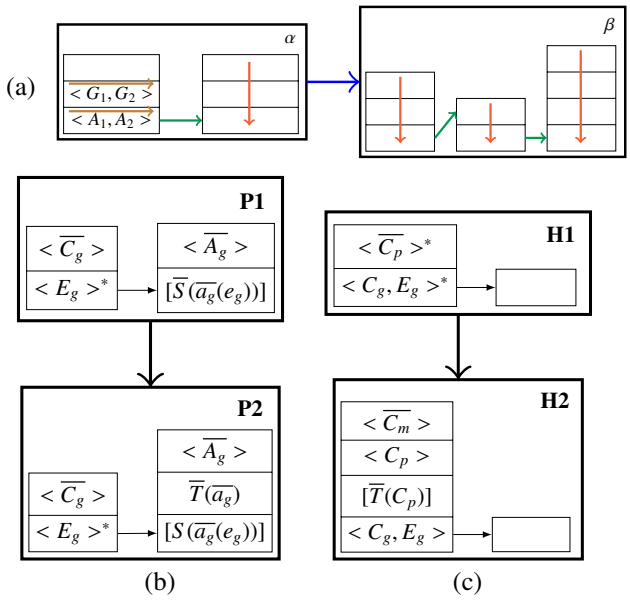

**Figure 1:** *(a) Key showing four types of timelines (b) Progression of a poetry system (c) Progression of the HR system.*

Thirdly, at run-time, data will be passed from process to process in series of creative and administrative **subprocesses** performed by software and programmer. Finally, each subprocess will comprise a sequence of generative or administrative **acts**. We capture these timelines diagrammatically, highlighted with coloured arrows in Figure 1(a). The blue arrow from box $\alpha$ to $\beta$ represents a change in epoch at system level. The red arrows overlapping a *process stack* represent causal development periods. The green arrows represent data being passed from one subprocess to another at run-time. The brown arrows represent a series of generative/administrative acts which occur within a subprocess.

Inside each subprocess box is either a < creative act > from the FACE model (i.e., a sequence of generative acts), or an [ administrative act ] which doesn't introduce any new concept, example, aesthetic or framing information/method. Administrative acts were not originally described in the FACE model, but we needed them to describe certain progressions of software. For our purposes here, we use only $T$ to describe a translation administrative act often involving programming, and $S$ to describe when an aesthetic measure is used to select the best from a set of artefacts. To add precision, we indicate the output from which generative act the administrative routine is applied, and to which examples a ground aesthetic is applied. To enable this, we employ the FACE model usage of lower-case letters to denote the output from the corresponding upper-case generative acts. We extend the FACE notion of (g)round and (p)rocess level generative acts with (m)eta level acts during which process generation methods are invented. As in the original description of the FACE model, we use bar notation to indicate that a particular act was undertaken by the programmer. We use a superscripted asterisk ($^*$) to point out repetition.

As a simple example diagram, Figure 1(b) shows the progression from poetry generator version P1 to P2. In the

first version, there are two process stacks, hence the system works in two stages. In the first, the software produces some example poems, and in the second the user chooses one of the poems (to print out, say). The first stack represents two timesteps in development, namely that (a) the programmer had a creative act $< \overline{C_g} >$ whereby he/she came up with a concept in the form of some code to generate poems, and (b) the programmer ran the software to produce poems in creative acts of the form $< E_g >^*$. The second stack represents the user coming up with an idea for an aesthetic, e.g., much rhyming, in creative act $< \overline{A_g} >$, and then applying that aesthetic $\overline{a_g}$ him/herself to the examples, $e_g$, produced by the software, in the *selection* administrative act $[\overline{S}(\overline{a_g}(e_g))]$, which maps the aesthetic $\overline{a_g} : \{e_g\} \rightarrow [0, 1]$ over the generated examples, and picks the best one. In the $P2$ version of the software, the programmer undertakes *translation* act $[\overline{T}(\overline{a_g})]$, writing code that allows the program to apply the rhyming aesthetic itself, which it does at the bottom of the second stack in box $P2$.

Figure 1(c) shows a progression in the HR automated theory formation system (Colton 2002) which took the software to a meta-level, as described in (Colton 2001). HR operates by applying production rules which invent concepts that categorise and describe input data. Each production rule was invented by the programmer during creative acts of the type $< \overline{C_p} >$, then at run-time, HR uses the production rules to invent concepts and examples of them in $< C_g, E_g >^*$ acts. In the meta-HR version, during the $< \overline{C_m} >$ creative act, the programmer had the idea of getting HR to form theories about theories, and in doing so, generate concept-invention processes (production rules) in acts of the form $< C_p >$. The programmer took meta-HR's output and translated $[\overline{T}(C_p)]$ it into an implemented production rule that HR could use, which it does at the bottom of the stack in box H2.

## Stage 2: Comparing Diagrams and Output

In both simple cases of Figure 1, it is clear that progress has been made in the strong sense, but not clear in the weak sense, as the output could easily be degraded by the more sophisticated processing of the systems. The diagrams help us to capture the creative interplay between software and programmer at design time and run time. However, given that the ultimate aim of both strong and weak projects is to impress audiences with process and product, any assessment of progress must be done in a context of audience evaluation. However, as mentioned previously, audience evaluation is too expensive to help assess progress on a day to day basis. Hence, it seems sensible for the programmer to step in and act as a proxy for a perceived audience: we advocate the programmer putting themselves in the position of the type of person they would expect to form their audience, and answer questions about the products and processes accordingly.

Examining the transition from one diagram to another should provide some shortcuts to estimate audience reactions, especially when there are strong project objectives. In particular, as with the original FACE model, the diagrams make it obvious where creative or administrative responsibility has been handed over to software, namely where an act which used to be barred has become unbarred, i.e., the same type of generative act still occurs, but it is now performed by software rather than programmer. This happened when the $\overline{S}$ became an $S$ in Figure 1(b) and when the $\overline{C_p}$ became a $C_p$ in Figure 1(c). At the very least in these cases, an unbiased observer would be expected to project more autonomy onto the software, and so progress in the strong sense has likely happened. In addition, the diagrams make it obvious when software is doing more processing in the sense of having more stacks, bigger stacks or larger tuples of acts in the stack entries. Moreover, the diagrams make it clear that more varied or higher-level creative acts are being performed by the software – again, this was one of the benefits of the original FACE model. Both of these have the potential to convince audience members that software is being more sophisticated with respect to various behaviours described below, and hence can be a shorthand for progress.

When dealing with actual external evaluation, where people don't know what software does, we suggest that the diagrams above (and verbalisations/simplifications of them) can be used to describe to audiences what the software and what the programmer have done in a project. In this way, using also their judgements about the artefacts produced, people can make fully informed decisions in evaluation studies. As a general philosophical standpoint, we suggest not asking people if they believe software is behaving creatively, but rather concentrating on whether they perceive the software as acting *uncreatively*. Our argument for this is that the concept of creativity is essentially contested (Gallie 1956), hence, no matter how sophisticated our software gets, we should not expect consensus on such matters. However, we have found that people agree much more on notions of uncreativity: if a program doesn't exhibit behaviours onto which certain words like *intentionality* can be projected, then it is very easy to condemn it as being uncreative.

Hence, we advocate not asking a set of questions from which we can conclude that an audience member thinks that software is creative, but rather asking questions from which we can determine whether they think that software is acting uncreatively. It may seem like rather a negative admission, but we believe that the best way to get people to accept software as being creative is for them to eventually realise that there is no good reason to call it uncreative. Even then, people would be perfectly at liberty to say that while software is not uncreative, it is not creative either: creativity and uncreativity do not appear to be exact opposites. With this in mind, we have boiled down audience evaluation of behaviour to asking people whether they would project certain words onto software in reaction to understanding what it did in the context of a particular project. We then tentatively conclude that they believe the software is uncreative if they don't project onto it some or all of these words, as originally intended in the creativity tripod proposition (Colton 2008b).

In the five years since the introduction of the creativity tripod, we have slowly added additional behaviours which we have found to be important in the perception of creativity in software. That is, for people to take seriously software as being not uncreative, we believe it needs to exhibit behaviours onto which people can meaningfully project (at least) these

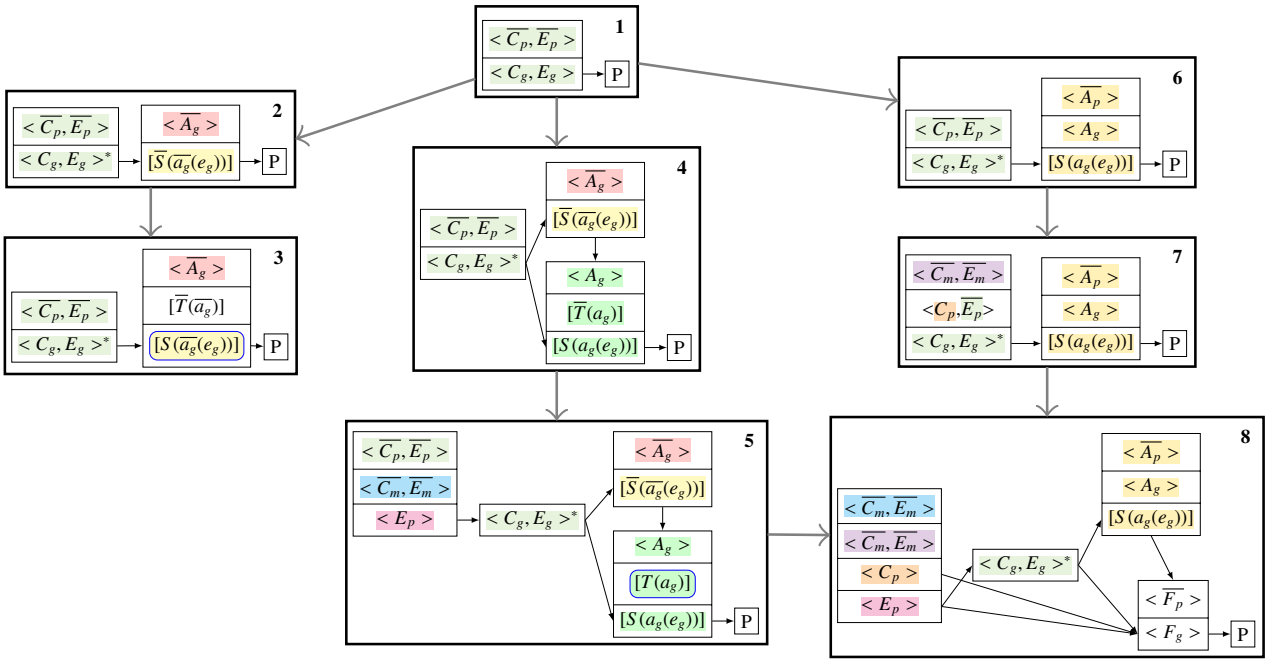
| Product change | Process change | Weak | Strong |
|---|---|---|---|
| Up | Up | OP | OP |
| Up | Down | PP | PR |
| Up | Same | OP | PP |
| Down | Up | PR | PP |
| Down | Down | OR | OR |
| Down | Same | OR | PR |
| Same | Up | PP | OP |
| Same | Down | PR | OR |
| Same | Same | PP | PP |

**Table 1:** Guidelines for using change in evaluation of product and process in gauging (O)bvious or (P)otential (P)rogress or (R)egress, in both weak and strong agendas.

eight words: skill, appreciation, imagination, learning, intentionality, accountability, innovation, subjectivity and reflection. We have found that assessing the level of projection of these words onto the behaviours of software can help us to gauge people's opinions about (the lack of) important higher-level aspects of software behaviour, such as autonomy, adaptability and self-awareness.

The method we suggest for estimating progress from version $v1$ of a creative system to version $v2$ is to: (a) show audience members the diagrams for $v1$ and $v2$ as above, and explain the acts undertaken by the software, then (b) show audience members the output from $v1$ and $v2$, and (c) ask each person to compare the pair of product and process for $v1$ with that of $v2$. A statistical analysis could then be used to see whether the audience as a whole evaluates the output as being better, worse or the same, and whether they think that the processing is better, worse or the same in terms of the software seeming less uncreative. This takes into account the phenomenon described in (Colton 2008b) whereby the process can influence value judgements for artefacts.

To use this analysis to estimate progress, it's important to first prioritise objectives for the project locally in terms of strong and weak agendas. Then, taking the audience evaluation of change in output and in process, we suggest using the guidelines in Table 1. Here, we have stipulated that certain evaluation pairs indicate obvious progression (OP) or obvious regression (OR). For instance, in the weak sense, when the evaluation of output goes up and the evaluation of process increases or stays the same, it seems clear to indicate obvious progress. Other cases are not so clear-cut, for instance when evaluation of artefacts goes up, but evaluation of process goes down. In this case, we suggest that this is potential progress (PP) in a weak agenda, and potential regress (PR) in a strong agenda. In such cases, we give our judgements for whether it is likely, after more development, that $v2$ will be viewed retrospectively as a progressive success or a step backwards. Note that we have tended to be optimistic, e.g., when evaluation of output and process stay the same, we say that this is potential progress in both weak and strong agendas. Note also that this table is meant to be used flexibly, possibly in a context of more fine grained analysis. For instance, the focus of a subproject might be to increase audience perception of intentionality, and if this increases while audience perception of the value of the process as a whole reduces, it should still be seen as progress.



## A Case Study in Evolutionary Art

Evolutionary art – where software is evolved which can generate abstract art – has been much studied within Computational Creativity circles (Romero and Machado 2007). Based on actual projects which we reference, we hypothesise here the various timelines of progress that could lead from a system with barely any autonomy to one with nearly full autonomy. Figure 2 uses our diagrammatic approach to capture three major lines of development, with the final (hypothetical) system in box 8 representing finality, in the strong sense that the software can do very little more creatively in generating abstract art. Since features from earlier system epochs are often present in later ones, we have colour-coded individual creative acts as they are introduced, so the reader can follow their usage through the systems. If an element repeats with a slight variation (such as the removal of a bar), this is highlighted. The figure includes a key, which describes the most important creative and administrative acts in the systems. Elements in the key are indexed with a dot notation: *system.process-stack.subprocess* (by number, from left to right, and top to bottom, respectively). System diagrams have repetitive elements, so that the timelines leading to its construction and what it does at run-time can be read in a stand-alone fashion.

Following the first line of development, system 1 of Figure 2 represents an entry point for many evolutionary art systems: the programmer invents ($\overline{C_p}$) (or borrows) the concept formation process of crossing over sets of mathematical functions to produce offspring sets. He/she also has an idea ($\overline{E_p}$) for a *wrapper* routine which can use such a set of functions to produce images. He/she then uses the program to generate ($C_g$) a set of functions and employ the wrapper to produce ($E_g$) an image which is sent to the (P)rinter. The crossover and subsequent image generation is repeated multiple times in system 2, and then the programmer – who has invented ($\overline{A_g}$) their own aesthetic – chooses a single image to print. In system 3, as in the poetry example above, the programmer translates their aesthetic into code so the program can select images. This is a development similar to that for the NEvAr system (Machado and Cardoso 2002).

Following the second line of development, in system 4, the programmer selects multiple images using his/her own aesthetic preferences, and these become the positives for a machine learning exercise as in (Li et al. 2013). This enables the automatic invention ($A_g$) of an aesthetic function, which the programmer translates by hand $\overline{T}(a_g)$ from the machine learning system into the software, as in (Colton 2012), so the program can employ the aesthetic without user intervention. In system 5, more automation is added, with the programmer implementing their idea ($\overline{C_m}$) of getting the software to search for wrappers, then implementing this ($\overline{E_m}$), so that the software can invent ($E_p$) new example generation processes for the system.

Following the final line of development, in system 6, we return to aesthetic generation. Here the programmer has the idea ($\overline{A_p}$) of getting software to mathematically invent fitness functions, as we did in (Colton 2008a) for scene generation, using the HR system (Colton 2002) together with The Paint-

| ID | Event | Explanation |
|---|---|---|
| 1.1.1 | $\overline{C_p}$ | The programmer invents the idea of crossing over two sets of mathematical functions to produce a new set of mathematical functions. |
| 1.1.1 | $\overline{E_p}$ | The programmer implements a wrapper method that takes a set of mathematical functions and applies them to each $(x, y)$ co-ordinate in an image to produce an RGB colour. |
| 1.1.2 | $C_g$ | The software generates a new set of functions by crossing over two pairs of functions. |
| 1.1.2 | $E_g$ | The software applies these functions to the $(x, y)$ co-ordinates of an image, to produce a piece of abstract art. |
| 2.2.1 | $\overline{A_g}$ | The programmer had in mind a particular aesthetic (symmetry) for the images. |
| 2.2.2 | $\overline{S}(\overline{a_g}(e_g))$ | The programmer uses his/her aesthetic to select a preferred image for printing. |
| 3.2.2 | $\overline{T}(\overline{a_g})$ | The programmer took their aesthetic and turned it into code that can calculate a value for images. |
| 3.2.3 | $S(\overline{a_g}(e_g))$ | The software applies the aesthetic to select one of a set of images produced by crossover and the wrapper. |
| 4.3.1 | $A_g$ | The software uses machine learning techniques to approximage the programmer's aesthetic. |
| 4.3.2 | $\overline{T}(a_g)$ | The programmer hand-translates the machine learned aesthetic into code. |
| 4.3.3 | $S(a_g(e_g))$ | The software applies the new aesthetic to choosing the best image from those produced. |
| 5.1.2 | $\overline{C_m}$ | The programmer has the idea of getting the software to search through a space of wrapper routines. |
| 5.1.2 | $\overline{E_m}$ | The programmer implements this idea. |
| 5.1.3 | $E_p$ | The software invents a new wrapper. |
| 5.4.2 | $T(a_g)$ | The software translates the machine-learned aesthetic itself into code. |
| 6.2.1 | $\overline{A_p}$ | The programmer has the idea of getting the software to invent a mathematical fitness function. |
| 6.2.2 | $A_g$ | The software invents a novel aesthetic function. |
| 6.2.3 | $S(a_g(e_g))$ | The software selects the best artefact according to its aesthetic function. |
| 7.1.1 | $\overline{C_m}$ | The programmer has the idea of getting the software to invent and utilise novel combination techniques for sets of functions, generalising crossover. |
| 7.1.1 | $\overline{E_m}$ | The programmer implements this idea so that the software can invent new combination techniques. |
| 7.1.2 | $C_p$ | The software invents a novel combination technique. |
| 8.4.1 | $\overline{F_p}$ | The programmer has the idea of getting the software to produce a commentary on its process and artwork by describing its invention of a new aesthetic, combination method and wrapper. |
| 8.4.2 | $F_g$ | The software produces a commentary about its process and product. |

**Figure 2:** *The progression of an evolutionary art program through eight system epochs.*

ing Fool (Colton 2012b). In system 7, the programmer realises ($\overline{C_m}$) that crossover is just one way to combine sets of functions, and gives ($\overline{E_m}$) the software the ability to search a space of combination methods ($C_p$). The software does this, and uses the existing wrapper to turn the functions into images. System 8 is the end of the line for the development of the software, as it brings together all the innovations of previous systems. The software invents aesthetic functions, innovates with new concept formation methods that combine mathematical functions, and generates new wrappers which turn the functions into images. Finally, the programmer has the idea ($\overline{F_p}$) of getting the software to write commentaries, as in (Colton, Goodwin, and Veale 2012), about its processing and its results, which it does in generative act $F_g$.

Tracking how the system diagrams change can be used to estimate how audiences might evaluate the change in processing of the software, in terms of the extended creativity tripod described above. Intuitively, each system represents progress from the one preceding it, justified as follows:

**1 → 2**: $< C_g, E_g > \rightarrow < C_g, E_g >^*$

Simple repetition means that the software has more *skill*, and the introduction of independent user selection shouldn't change perceptions about *autonomy*.

**2 → 3**: $\overline{S} \rightarrow S$

By reducing user intervention in choosing images, the software should appear to have more *skill* and *autonomy*.

**1 → 4**: Introduction of $A_g$ and $S(a_g(e_g))$ acts

Machine learning enables the generation of novel aesthetics (albeit derived from human choices), which should increase perception of *innovation*, *appreciation* and *learning*, involving more varied creative acts.

**4 → 5**: Introduction of an $E_p$ act, $\overline{T} \rightarrow T$

Wrapper generation increases variety of creative acts, and may increase perception of *skill* and *imagination*.

**1 → 6**: Introduction of $A_g$ and $S(a_g(e_g))$ acts

The software has more variety of creative acts, and the invention and deployment of its own aesthetic – this time, without any programmer intervention – should increase perception of *intentionality* in the software.

**6 → 7**: Introduction of a $C_p$ act

Changes in the evolutionary processes should increase perceptions of *innovation* and *autonomy*.

**5, 7 → 8**: Introduction of an $F_g$ act

Framing its work should increase perceptions of *accountability* and *reflection*.

With all strands brought together, the programmer does nothing at run-time and can contribute little more at design time. The software exhibits behaviours onto which we can meaningfully project words like skill, appreciation, innovation, intentionality, reflection, accountability and learning, which should raise impressions of autonomy, and make it difficult to project uncreativity onto the software.

## Discussion

Capturing what programmers and software do creatively over long periods and during complicated program executions is difficult and open to variability. The systems in the above case study could easily have been interpreted and presented differently. In essence, we have provided some tools for presenting software development in terms of creative acts, and suggested a mechanism for turning audience perceptions into estimates of progress. We advise flexible application in both cases. In particular, the difference between potential progress and potential regress is quite subtle. Both mean that it is too early to determine whether progress or regress has been made, and the programmer should proceed with caution: the former suggesting cautious optimism and the latter, cautious pessimism. Practically speaking, the programmer may want to review longer term goals, archive previous versions, and/or clarify research directions.

Our approach is currently more tailored to capturing progress in software behaviour than its output. We would understand some resistance to the approach, particularly from researchers with agendas for Computational Creativity in the weak sense. For example, if product evaluations remain the same, yet processing evaluations go up, this is presumably because the software is performing more sophisticated routines. From a weak perspective, the simpler version of the software clearly has advantages, as it produces the same results in a more understandable way. In certain application domains, for instance mathematical discovery, where aesthetics like truth are of paramount importance, a simpler method for finding a result is usually preferred. While reducing complexity of processing normally requires considerable invention or intervention, unless such invention is done by the software itself, the resulting simplicity would tend to increase perceptions of uncreativity in software, regardless (or, indeed, because of) how easy it is to understand what it has done.

Our approach is also more tailored towards capturing progress from version to version of the same software than to comparing different programs. However, we have used the formalism to compare systems in the same application domains, such as mathematical discovery systems AM (Lenat 1976) and HR (Colton 2002), and various poetry and art generators. The comparative approach works somewhat here, because it was possible to compare diagrams meaningfully to suggest where one system would likely be perceived as an improvement over the other. However, full application of the approach may be difficult as the context for evaluating artefacts (and the processes producing them) can change greatly with small changes in artefact composition. For instance, we recently attempted to compare one-line "What if...?" ideas produced textually by three systems. We found that it was not possible to conceive a fair approach involving an audience to determine which system's artefacts or processes were the best. Fields like Machine Learning have largely homogenised the testing of their systems in a problem-solving paradigm. Given the tacit requirements for software to surprise us through its output and processing, and to innovate on many levels, it seems unlikely that such standardisation could apply in Computational Creativity research.

## Related Work

Diagrammatic approaches to software modelling have been extensively studied in the last two decades. The best known example is the Unified Modelling Language (UML), managed by the Object Management Group (OMG), a standard that is widely used to visualize the design of systems (`www.omg.org/spec`). The main objectives of modelling with UML are to represent the architecture of a system, including use cases, deployment, information flow diagrams, etc., and to model system behaviour and data flow via activity diagrams, state machines, sequence diagrams, etc.

Progress at the process level can be modelled with UML by diagramming the steps used to complete a task within the system. However, UML is not typically applied to model progress at the level of system epochs, although two UML diagrams can of course be compared on the basis of the functionality they describe. Some diagrams created using the UML model, such as use case diagrams, enable designers to specify the agents that participate in the development of a system: people, external processes, other systems and the system itself can all be modelled as agents. However, there is no formal notation to distinguish between the different agents, rather, they are simply assigned a label which is meaningful for the system designer. The OMG have also developed other graphical notations specialised for other aspects of systems modelling. For instance, the Business Process Model and Notation (BPMN) is used to model business processes by extending the original activity diagrams of UML. The specific objective of BPMN is to provide a high-level overview of business systems, rather than detailed information about how the system works.

UML diagrams have also been used in the context of formal methods. In particular, the UML-B language (Said, Butler and Snook 2009) enables the modelling of Event-B specifications as UML-like diagrams. Event-B is a formalism based on set theory for the modelling and verification of systems (Abrial 2010). One of the main aspects of Event-B is the use of refinement to handle the complexity of systems at different levels of abstraction. UML-B can be used to diagrammatically model a system at increasing levels of refinement, and system consistency can then be verified through mathematical proof. However, UML-B considers one system at a time, so it is not possible to use this formalism to model creative change as system development progresses.

Using the Event-B formalism, it is possible to model aspects of the environment, such as external systems that affect the behaviour of the modelled system. The aim is to ensure that the designed system will work in harmony with its operating environment. However, there is no clear way to delimit the aspects of the model that are related to the environment and those that are part of the final system. Again, the environment is simply identified by the designer assigning meaningful names to the state representing it. Other related approaches include Z-notation (Spivey 1992), the Vienna Development Method (Jones 1990) and the B-method (Abrial 1996). The objective of these approaches is to verify properties of systems. Progress would be meaningful at the modelling level, i.e., by building models that offer increasing detail (and assurance) about how a given system works.

Petri nets provide a graphical notation used primarily to model systems with concurrency (Girault and Valk 2003). With petri nets, progress at the process level is modelled in the form of state transitions, and data is represented by abstract tokens, with no data values assigned. An extension, called coloured petri nets (Jensen and Kristensen 2009), allow data values to be assigned to tokens. Neither type of petri net is used for modelling changes through versions of a system. Petri nets are an event-based modelling language and representations of agents (such as the programmer or the system) are not included in the formalism.

## Conclusions and Future Work

We have presented a new diagrammatic formalism for assessing progress in building creative systems. Our aims were to enable more precise understanding of progress in Computational Creativity in general, and in mapping the progress of particular systems. In doing so, we aimed to bring closer together public/peer appreciation of progress, strong/weak agendas, and day-to-day/milestone progress assessments. The new approach involves producing diagrams of systems that depict creative acts in timelines, which are compared in a context of audience evaluation of process and product. When applied, the formalism captures some intuitive notions, including: quality of artefacts; quantity, level and variety of creative acts performed; and audience perception of software behaviour. To enable better understanding of process, and more informed audience judgements about (un)creativity, the diagrams explicitly separate creative acts coming from the programmer and the program. Even in the absence of audience participation, the diagrams themselves can be used in combination with straightforward assumptions about audience reactions to system design features to perform low-cost estimates of progress in a strong agenda.

We motivated the approach throughout with various philosophical standpoints, as per (Colton et al. 2014), supported by a critical review of the ways in which progress in building creative systems has been measured historically. To highlight the potential for the formalism, we presented a case study where the progress through eight versions of evolutionary art software was mapped and justified.

Our audience evaluation model is far from complete. We plan to employ the criteria specified in (Ritchie 2007), for more fine-grained evaluations of the quality, novelty and typicality of artefacts. We will also import audience reflection evaluation schemes from the IDEA descriptive model, e.g., change in well-being, cognitive effort and emotional responses such as surprise and amusement. We have so far used the diagrammatic approach to fully depict timelines in the building of generative software producing mathematics, visual art, poetry and video games, including dozens of system diagrams (omitted for space reasons). This has worked well, but there are still some subtle improvements required to capture better the functioning of the software at run-time.

(Gabriel and Goldman 2000) describe system development environments with many contributing programmers, and multiple interacting, self-programming, and self-updating distributed systems (Gabriel and Goldman 2006). It would be straightforward to modify our formalism to deal

with multiple agents, for example by turning bars into superscripts. However, this does complicate the notion of progress: if system $\mu$ chooses to hand off creative control to system $\nu$, this would amount to changing a superscript – but it's not immediately clear that this should count as progress in the same way that removing bars does. If the agents are considered to be full partners in the creative process, $\mu$ and $\nu$ may well have their own perspectives on what counts as progress, and this needs to be formalized.

Broadly speaking, we expect that the distinction between strong and weak agendas will eventually disappear: in order to produce higher quality artefacts, more sophisticated systems involving behaviours perceived as creative will be required, and audiences will expect to project notions of creativity onto software to fully appreciate its output. In such a context, assessing processes and products simultaneously will be important, and we hope versions of this diagrammatic approach will enable this. In (Colton, Goodwin, and Veale 2012), we used the FACE model as a driving force for poetry generation software, rather than as a descriptive tool. We hope that system developers will similarly begin to think about their software in the above diagrammatic terms, in order to suggest interesting new avenues for implementation.

# Peer produced peer learning :

## A mathematics case study

*by*

Joseph Angus Corneli, B.A.

A thesis submitted in partial fulfillment of the requirements
for the degree of Doctor of Philosophy.

Knowledge Media Institute

Submitted July 31, 2013

# Abstract

This research project develops around a technological intervention intended to transform a peer produced reference resource into a peer produced learning environment. Through the work described in this thesis, PlanetMath.org, an early online community devoted to mathematics, has now become a mathematical practicum, and a laboratory for learning science.

A new theory that describes the nexus of peer production and peer learning is foundational for the research programme. The candidate theory was initially developed during a pilot study based on online field work at the Peer-2-Peer University. The new theory – which is given the name "paragogy" – has implications for designers, researchers, educators, and others whose work relies on peer learning and peer production. Further research and development work in the PlanetMath context helped to refine the theory, and applied it along with a range of mixed methods to develop an anthropologically-inspired study of modern mathematics.

A quantitative approach was employed to detect the factors of interaction that influence learning outcomes, using legacy data from PlanetMath. A qualitative, interview-based approach was employed, to understand the desiderata potential users of a new system emphasizing peer learning. The new software system was implemented, informed by paragogy and these stakeholder perspectives, using Drupal and other open source components. Field work with PlanetMath users after the launch of the new system employed an emergent design process to elaborate the theory and develop a viable approach to ongoing development and codesign.

# Acknowledgements

Peter Scott and Alexander Mikroyannidis supervised my work. Marian Petre and Martin Oliver examined it. I think they will all agree it has been a lot of work to get to this point.

Thank you for all of your help.

Thanks for help and inspiration, as well, to: Luther P. Gerlach, Pat McDonald, Timothy Teravainen, Rob Meyers, Caroline Arruda, Robert Cooksey, Frank Morgan, Kyle Schalm, Bruce Porter, Aaron Krowne, Raymond Puzio, Jim Pitman, Ella Kearney, Anders Amala, Nicole Asselin, Paul Mulholland, John McLear, Aleksandra Pawlik, Stefan Kreitmeyer, Katherine Killick, Michael Kohlhase, Andrea Kohlhase, Christoph Lange, Deyan Ginev, Constantin Jucovschi, Catalin David, Alex Dumitru, Bruce Miller, Lucas Anastasiou, Charlie Danoff, Marisa Ponti, Wouter Tebbens, Fabrizio Terzi, Howard Rheingold, Paola Ricuarte, Doug Breitbart, Anna Keune, Régis Barondeau, Charlotte Pierce, George Brett, Kyle Larson, Teryl Cartwright, Dorota Marciniak, Anesa Hosein, Alison Pease, Ursula Martin, Andrew Aberdein, Jamie Gabbay, Sir Timothy Gowers, Mohan Ganesalingam, Michael J. Barany, and Simon Colton.

> *There is a pool of blood somewhere, a place you came from. You will find this blood petrified into stone and it is red. It comes from a sacred spot common to all people, where even enemies are turned into friends and relatives.*
>
> *Lame Deer, Seeker of visions*, 1972

Among all my friends and relations I particularly wish to thank my father, Steve Corneli. I remember when I asked him for help with a geometry problem, and he said to me: "Do you just want the answer, or do you want to really understand how it works?" I was far too ashamed to admit that what I wanted was the answer, so I think I said, "Both." I thought about it some more afterwards, and realized, what I really wanted was a computer program that would help me understand how to get the answer. Well, I don't have the computer program yet. But I know a lot more about how it works.

Tables 11, 12, and parts of Chapter 9 appear in altered form in the *Peeragogy Handbook*.

Appendix B draws extensively on notes from a public lecture on "Modelling the mathematical discovery process" presented by Sir Timothy Gowers in his Maxwell Institute Lecture at the University of Edinburgh, November 2, 2012.

# Publications

Eleven recent peer reviewed publications helped to explicate the main ideas in the thesis in the context of academic dialog. These papers were published in venues devoted to wikis, open knowledge, learning design, learning science, computer mathematics, and commons governance. The thesis draws on and complements recent experiments with research-through-writing (Tomlinson et al., 2012), and joint work on the *Peeragogy Handbook* (Rheingold et al., 2014). The benefits of collaboration in research are particularly clear for research on collaboration, as this allows theoretical ideas about the topic of study to be developed and grounded in practice. The associated publication track record reflects the interdisciplinary and mediatedly-social nature of this project. That said, in conformity with academic norms, the text presented here remains the responsibility of a single author.

Chapter 2 (Historical Background):

- Joseph Corneli (2011), The PlanetMath Encyclopedia, in *Workshop on Mathematical Wikis (MathWikis-2011) at ITP (2nd International Conference on Interactive Theorem Proving) 2011, Nijmegen, NL, August 27th, 2011.*

  This paper provides a retrospective look at PlanetMath's first decade. This material is used to to develop a dispassionate perspective on PlanetMath's strengths and weaknesses.

Chapter 3 (Theoretical Background):

- Joseph Corneli and Alexander Mikroyannidis (2012), Crowdsourcing Education on the Web: A Role-based Analysis of Online Learning Communities, in Alexandra Okada, Teresa Conolly, and Peter Scott (eds.), *Collaborative Learning 2.0: Open Educational Resources*, IGI Global.

  This book chapter provides an analysis of learning in terms of its constituent roles. This is reassessed here, to better emphasize the importance of context.

- Joseph Corneli and Charles Jeffrey Danoff (2011), Paragogy, in *OKCon 2011: Proceedings of the 6th Open Knowledge Conference.*

  This was the first published paper on the paragogy framework, developed in a pilot study at the Peer-2-Peer University. Paragogy is the central idea that is developed in the thesis.

– Joseph Corneli and Alexander Mikroyannidis (2011). Personalised and Peer-Supported Learning: The Peer-to-Peer Learning Environment (P2PLE), *Digital Education Review*, 20.

  This paper reinterprets paragogy as a set of design principles. These are drawn upon to present a understand stakeholder perspectives on the PlanetMath re-build.

– Joseph Corneli, Paragogical Praxis, *E-Learning and Digital Media*, 9(3), 2012.

  This paper looks at the methods that people can use to "do" paragogy. Together with the design principles mentioned above, this work is used to develop a consistent framework for analysis of peer produced peer learning in terms of system change.

Chapter 5 (Methodology):

– Joseph Corneli and Marisa Ponti (2012), Detecting mathematics learning online, in Hodgson V., Jones C., de Laat M., McConnell D., Ryberg T. & Sloep P. (eds.), *Proceedings of the 8th International Conference on Networked Learning 2012*, 2-4 April, 2012, Maastrict, NL.

  This paper considers the prospects for modeling the causes of learning in an online context. The paper presented foundational designs for both a quantitative analytic approach, and a qualitative heuristic approach. These ideas are sharpened in Chapter 5 to describe the reseach methods that will be used in subsequent chapters.

Chapter 8 (Implementation):

– Joseph Corneli, Constantin Jucovschi, and Alexander Mikroyannidis (2011). PlanetMath Redux: Web 2.0 infrastructure for mathematical problem solving, in *Technology-Enhanced Learning for Mathematics and Science: Landmark Research and New Contributions (TELMAS@ECTEL'2011), September 21, 2011, Palermo, Italy.*

  This paper presented a preliminary outline of what it would mean to convert PlanetMath into a "learning environment." This is expanded here with a requirements analysis informed by research with stakeholders.

– Joseph Corneli and Mircea Alexandru Dumitru (2012). PlanetMath/Planetary, in *Proceedings of Works in Progress track, MathUI and OpenMath workshops at the Conferences on Intelligent Computer Mathematics 2012.*

  This paper presented a technical overview of the Drupal 7 based rebuild of PlanetMath's infrastructure. Chapter 8 presents an analysis of the deployed system, including screenshots.

Chapter 9 (User evaluation):

– Joseph Corneli, Dorota Marciniak, Charles Jeffrey Danoff, Charlotte Pierce, Paola Ricaurte, Jan Herder, Suz Burroughs, George Brett and John Graves (2014). Building the Peeragogy Accelerator, in Megan Quentin-Baxter, ed., *Proceedings of OER14: building communities of open practice*,

  This paper describes work-in-progress on project-to-project collaboration in the Peeragogy project, supported by a design pattern methodology. The approach to collaboration described in this paper informed my interpretation of user feedback on PlanetMath/Planetary.

Chapter 10 (Discussion):

– Joseph Corneli, Anna Keune, Amanda Lyons, and Charles Jeffrey Danoff (2013). Peeragogy in Action, in Kaitlyn Braybrooke, Jussi Nissilä and Timo Vuorikivi, eds., *The Open Book*, #3 in the Reaktio Series, published by The Finnish Institute in London, UK. ISBN 978-0-9570776-3-8.

  One key question in my discussion chapter is whether PlanetMath is useful for instructors, in practice. This book chapter a presents a general-purpose design for peer learning activities; it is instantiated here with a concrete example.

– Joseph Corneli (2014), Towards a Creativity Commons, *Fifth "Workshop on the Ostrom Workshop" (WOW5)*. Working group: "The Commons as Transformative Paradigm".

  This paper helped to clarify the philosophical issues underlying the design pattern methodology. I draw on this work to help explain the broader implications of the research presented here.

# Part 1
# Introduction

# 1 Studying Mathematics the Commons-Based Peer Production Way

**Mathematics is a socially shared, symbolically – and technologically – mediated *cultural* activity. This suggests that one way to understand mathematics better is to look at how people *do* mathematics.**

## 1.1 What this is and is not

This does not mean watching over individuals who are solving mathematics problems and taking notes on how often they look out the window and whether or not they ultimately get the correct answer. Nor will this study rely, for the most part, on the even more typical (and obvious) idea: being that person oneself. As Eugene Matusov argues:

> *Focusing on the individual as the unit of analysis blinds researchers and educators from seeing the systemic complexity of psychological phenomena and from considering systemic solutions to complex psychological and social problems.* (Matusov, 2007)

Rather than studying mathematics in the traditional way, by solving mathematics problems – or focusing exclusively on studying discrete instances of others' problem solving – the proposal is, to the extent possible, to study mathematics as a cultural system. In itself this perspective is not new. Ludwig Wittgenstein wrote that "*mathematics is after all an anthropological phenomenon*" (Wittgenstein, 1956, §V.26). Wittgenstein looked at the foundations of mathematics primarily through the lens of language. For example: "*A definition signifies a change in technique*" (Wittgenstein, 1976, p. 33).

In 1997–1998, as a beginning student of cultural anthropology and multivariable calculus, it occurred to me that mathematics was perhaps the ideal example of "culture",

when this is understood to mean:

> [S]*ocially acquired, symbolically mediated systems of techno-ecological adaptive strategy, organization* [...] *and cosmology*[.]
>
> Luther P. Gerlach, quoted in (Brandt, 2005)

At the time, my ambition to study mathematics as a participant observer meant doing the obvious thing and becoming a mathematics student. It was only later, when I became acquainted with current computational and computer-aided approaches to mathematics, that the foundations for the current study would begin to develop in earnest.

What I have more recently observed and participated actively in, and what will be described here, is the collaborative design and development of an online learning space for mathematics. This work features mathematical culture at its own most "cultural" level, and evokes "soft" cultural patterns – for instance, values pertaining to enculturation. To talk about enculturation rather than learning here is "*emphasizing not just a conditioning process but an adaptation process*" (Brandt et al., 2006). Indeed, at least in the current setting, this is a dual adaptation: not only of people to culture, but of the culture itself.

This study will explore the ways people think about mathematics and ramify their "native" theories and practices of mathematical culture. It will develop a theory of *peer produced peer learning*, inspired by and as a reflection on mathematical practice, but with broader implications. The work draws inspiration from anthropology and philosophy, but the methods and primary outcomes pertain to humanistic computing and to computer science. The following sections describe the research setting and approach, indicate the main scientific and practical contributions, and outline the argument of the thesis.

## 1.2 Setting and audience

> *PlanetMath is a virtual community which aims to help make mathematical knowledge more accessible. PlanetMath's content is created collaboratively: the main feature is the mathematics encyclopedia with entries written and reviewed by members.*
>
> Aaron Krowne, c. 2001, on HTTP://PLANETMATH.ORG

The PlanetMath encyclopedia currently defines over 15000 mathematical terms, covering both basic and advanced mathematical topics. Each page in the encyclopedia is accompanied by a threaded forum discussion. The development of the site and its highly custom software was the central topic in Aaron Krowne's Masters thesis, *An Architecture for Collaborative Math and Science Digital Libraries* (Krowne, 2003A).

PlanetMath's byline is "*math for the people, by the people.*" It is an example of a resource created through "*non proprietary production by peers who do not interact either through a firm or through a market*" (Benkler, 2002); in short, PlanetMath is *peer produced.* As Chapter 2 explains, a particular sort of wholly virtual ownership underlies PlanetMath's original design, but the site is nevertheless a "*community-managed commons*" (Gardner & Stern, 1996).

Although the encyclopedia is historically PlanetMath's central feature, it is not the project's sole commitment. PlanetMath is better described as a mathematics digital library built "*the commons-based peer production way*" (Krowne, 2003в). In a joint paper exploring potential new directions for the project, we wrote:

> *We find it compelling that, in the context of a digital library, marginal conversations within a text provide a chance for readers to interact with primary authors and with each other, and to become primary authors themselves, all at once. While marginalia are considered to be vandalism in physical library books, in a digital library, there is no reason to fear them – they can easily be hidden away.* (Corneli & Krowne, 2005)

The research question that I will be concerned with here is:

> What is needed to transform this peer produced digital library and mathematics reference resource into a peer produced peer learning environment?

The historical audience of the PlanetMath website was anyone who might consult an online encyclopedic dictionary of mathematics, or who would use a forum to discuss questions about mathematics. This population includes advanced undergraduates, graduate students, mathematics professors, and professionals. The historical co-creators of PlanetMath formed a very particular subset of this population. These were people who were interested in discussing mathematics over the internet, asking questions and sharing existing knowledge, and often learning in the process. Certainly, this was peer produced peer learning, but learning was not the focus – creating an encyclopedia was. Chapter 2 traces the history of the PlanetMath project, and sets the stage for its potential evolution.

My hope is that in the future, PlanetMath's audience – or better still, its public – will expand to include anyone who might consult a mathematics textbook or Schuams outline, or who might take or design an online mathematics course, tutorial, or seminar. Users will be able to collectively inquire into the techniques and approaches that work best, using PlanetMath as a laboratory. Much as GNU/Linux offers a complete free operating system for computers, PlanetMath or its eventual successor may expand to be a go-to place for mathematicians, mathematics teachers, and students at all levels.

For now, however, there are a range of technical issues at stake which limit the scope of the current work to a far more modest scale, and which correspondingly narrows the range of users served. The technical focus of the current work is on building infrastructure that supports sharing, discussing, and solving textbook-style problems at the university or beginning graduate level. A prototypical user would be anyone doing independent study of mathematics at this level – whether or not they are formally enrolled as a student. The particular audience that the research focuses on are those socially-minded independent learners who would be interested in benefiting from or contributing to peer support using this technology.

A concrete use case can be described, building on an essay by computer scientist Clayton Lewis, who writes about the new potential of "DIY Education". In order to explore this theme, Lewis imagines himself caught in a time warp. Whereas $\text{Clayton}_{1963}$ "*lived in the dormitories of the college he attended*," due to the rising costs of education, $\text{Clayton}_{2010}$ "*has no such easy choice*" (Lewis, 2010). He looks around for free or low-cost options, and discovers the Peer 2 Peer University.*

> *Following his computer interests, Clayton explores the course offerings at P2P U. He's attracted by the Python programming course, and also by a cooperative program in Web technology offered jointly by P2P U and the Mozilla Foundation, World of Webcraft. He also thinks about Differential Equations for Engineers, but is put off by the fact that it isn't pure math, something about which he has a childish prejudice. He does sign up for DIY Math, facilitated by a doctoral student at the Open University, because it is open as to topic. He has a vague idea that there should be some interesting mathematics around games, not what is called "game theory", which he has read enough about to know isn't what he's interested in, but something that allows one to analyze games like penning the pig. (He doesn't know that this is called "combinatorial game theory".) He's hoping that the people in DIY Math can help him find something like that. P2P U has no requirements structure, so he doesn't sign up for anything outside his areas of interest.* (Lewis, 2010)

However, as Chapter 3 will demonstrate, *DIY Math* would actually be a singularly bad choice. One problem is that in following his own interests, $\text{Clayton}_{2010}$ "*doesn't have the guiding hand of curriculum* [...] *because P2P U doesn't have a curriculum.*" Nevertheless, Lewis points out that:

> *Anyone could create* [...] *a roadmap for learning in a particular field, or a roadmap for becoming "an educated person" in any more general sense they fancy, and share this via P2P U.* (Lewis, 2010)

One of the key aims behind the changes to PlanetMath is to support the creation, sharing, and critique of such learning roadmaps for the mathematics domain. In addition to peer learning, there is a complementary use case related to peer teaching.

*HTTP://P2PU.ORG

Folded inside of this point there is an important question. If both peer teaching and peer learning are important here, what about other roles? In particular, what about the person or persons who will be involved with creating the website, which offers suitable conditions for others to teach and learn? This points to a very important secondary audience, both for this thesis and the accompanying new software system, which has been been developed and released as free software. These aim to reach the people whose contributions will continue to drive the system forward.

## 1.3 The relevance of an anthropologically informed approach

The studies developed in this thesis are not ethnographic, but I view them as anthropological in spirit. As Tim Ingold explains, "*anthropology is not ethnography*" (Ingold, 2008). He offers this perspective on what anthropology can be: "*Quite simply, it would be an inquiry into the conditions and possibilities of social life, at all times and everywhere*" – in contrast to the more limited "*objective of ethnography*," which is "*to describe the lives of people other than ourselves.*" A lot hinges on Ingold's understanding of "*social life.*" He writes: "*Societies are not entities analogous to organisms, let alone to machines.*" Indeed, he takes an opposite view: "*Organic life is social.*" Ingold's socially-inspired and process-oriented ontology refers to the "*essential interpenetrability or commingling of mind and world*" and to "*the unfolding of a continuous and ever-evolving field of relations within which beings of all kinds are generated and held in place.*"

Ingold's philosophical views are connected to an approach to inquiry that has significant bearing on the approach that will be taken here.

> *What truly distinguishes anthropology, I believe, is that it is not a study **of** at all, but a study **with**. Anthropologists work and study **with** people. Immersed with them in an environment of joint activity, they learn to see things (or hear them, or touch them) in the ways their teachers and companions do.* (Ingold, 2008), original emphasis

A system like PlanetMath is an approximate description, in an active rather than static form, of the way mathematics is done. At its best, such a system simultaneously creates new ways to do mathematics. In the last analysis, the interpretation of mathematical practice at PlanetMath is an interpretation made together with the user community. Notably, if the system is entirely incongruous with what mathematical practice *is*, then people who are interested in mathematics will have very little use for it!

In expanding the theme of "*studying with*," Ingold emphasizes that he is ultimately far less interested in "*description*" than in "*a practice of correspondence.*" In a recent book bringing anthropology together with archaeology, art, and architecture, he writes:

> *To practise this method is not to describe the world, or to represent it, but to open up our perception to what is going on there so that we, in turn, can respond to it.*
> (Ingold, 2013, p. 7)

For Ingold, after Lave (1990), learning is "*understanding in practice*," and after Gibson (1979), it is based upon "*an education of attention*," which is, drawing on his own fieldwork experiences, "*a process of active following*" (Ingold, 2013, pp. 9, 13, 2, 1). These points are are not discipline-specific: they apply equally to hunting and pottery-making, computer programming and mathematics.

The key feature of Ingold's anthropology that brings it closer to art than to ethnography is that it aims to be "*transformational*" rather than "*documentary*" – here noting that "*no genuine transformation in ways of thinking and feeling is possible that is not grounded in close and attentive observation*" (Ingold, 2013, pp. 3-4).

The fundamental place that Ingold reserves for the social in his thinking bears a similarity to George Herbert Mead's conception, which again emphasizes transformation. For Mead (1932), sociality is the "*stage betwixt and between the old system and the new one*," which occurs whenever a new form of organization is being established, but when neither the new form nor the broader environment has stabilized; *cf.* (Aboulafia, 2012). A view in which the environment is not taken as fixed, but as co-emergent with the people who dwell in it is reflected in the PlanetMath context, in the sense that both content and software are expected to grow and develop along with use.

One further quote can be brought forward to illustrate the essential idea of "*studying with people*" that underlies Ingold's participatory anthropology. This quote describes peer learning in negative form – in other words, it says how things are usually done in mainstream education.

> *Students are told that anthropology is what we do with our colleagues, and with other people in other places, but not with them. Locked out of the power-house of anthropological knowledge construction, all they can do is peer through the windows that our texts and teachings offer them.* (Ingold, 2008)

In the parallel setting of mathematics, there are some exemplary exceptions to this norm. Educator Alan Schoenfeld, who describes *metacognition* as the key to working effectively in mathematics (Schoenfeld, 1987), builds his pedagogical practice around asking his students reflective questions like these:

> *What (exactly) are you doing? Can you describe it precisely? Why are you doing it? How does it fit into the solution? How does it help you? What will you do with the outcome when you obtain it?* (Schoenfeld, 1987, p. 206)

He argues that

> [T]*he interactions among mathematicians, and the sense of community they support, are part of what sustains mathematics – that the practice of mathematics is a human endeavor and very much a cultural one.* [...] [E]*ntry into that culture (or some culture that supports the same values) may be necessary to understand and appreciate mathematics.* (Schoenfeld, 1987, p. 214)

Schoenfeld asserts that, for practicing mathematicians, the classroom "*is an essentially alien culture*," and that "[w]*hat we need is a program of 'cultural design' for schooling.*"

## 1.4 What (exactly) is to be done

Having described a basic outlook in which mathematics is seen as a cultural and indeed as an already-anthropological affair, it remains to say what concept of culture is most relevant to the study of mathematics, and what will be done here using this concept. The "*socially acquired, symbolically mediated systems*" definition from Gerlach, quoted above, provides a useful big picture, but in its breadth, it does not exactly give a notion of culture that we can easily grasp. It is, however, compatible with a pointed cybernetic notion of culture, developed by Clifford Geertz. First, a bracketing admonition:

> *Culture is not a power, something to which social events, behaviors, institutions, or processes can be causally attributed; it is a context, something within which they can be intelligibly – that is, thickly – described.* (Geertz, 1973, p. 14)

Without yet worrying about the issues attached to these ideas of context and thick description, the following quote provides a working definition of what *culture* itself can be taken to mean:

> *I want to propose two ideas. The first of these is that culture is best seen not as complexes of concrete behavior patterns – customs, usages, traditions, habit clusters – as has, by and large, been the case up to now, but as a set of control mechanisms – plans, recipes, rules, instructions (what computer engineers call "programs") – for the governing of behavior. The second idea is that man is precisely the animal most desperately dependent upon such extragenic, outside-the-skin control mechanisms, such cultural programs, for ordering his behavior.* (Geertz, 1973, p. 44)

So, for Geertz, culture is already-programming![*] Of course it has, by and large, up to now, been programming for humans, not for computers. It is also important to point out that Geertz is explicitly referring to *cybernetic* programming. In other words, his

[*]Geertz's notion of culture derives from that of Talcott Parsons – "*patterned or ordered systems of symbols which are objects of the orientation of action, internalized components of the personalities of individual actors and institutionalized patterns of social systems*" (Parsons, 1951) – "*suitably emended*"; *cf.* (Geertz, 1973, pp. 254), (Peacock, 1981).

concept of cultural control systems "*presupposes that control is partial and not complete*" (Burroughs, 1978).

In light of Ingold's emphasis on trained attention and in-the-world experience, it is not surprising that he is suspicious of the idea of culture as an external control system. In a survey that treats Geertz and other prominent anthropological figures, he writes:

> [O]*ne learns to perceive in the manner appropriate to a culture, not by acquiring programmes or conceptual schemata for organising sensory data into higher-order representations, but by 'hands-on' tasks whose successful fulfilment requires a practised ability to notice and to respond fluently to salient aspects of the environment.*
>
> (Ingold, 2000, p. 167)

And yet, cybernetic control systems are not acquired in the way we might learn a second (or first) language; culture is primarily context, not content; *cf.* (Ingold, 2000, pp. 163–166). Rather, one might say that these systems are present, as more or less salient features of an environment, on the understanding that these features are emergent along with those who dwell in the environment. Whereas Geertz calls "*any object, act, event, quality, or relation which serves as a vehicle for conception*" a "*symbol*" (Geertz, 1973, p. 91), Ingold seems to be more cautious: "*every feature* [of the landscape] *is a potential clue, a key to meaning rather than a vehicle for carrying it*" (Ingold, 2000, p. 208).

Independent of the precise weight we assign to symbol systems as opposed to meaning making, it would be hard to deny that one the greatest cultural shifts in history is connected with the fact that, in recent decades, certain classes of symbolically-mediated programs can be processed with computers. Granted, people continue to perform "*actions that are far beyond the capabilities of any machine yet devised*" (Ingold, 2000, p. 171). What's of interest here is what happens when humans and computers work together.

> *We have been programming universal computers for about 50 years. Programming provides us with new tools to express ourselves. We now have intellectual tools to express "how to" as well as "what is." This is a profound transformation: it is a revolution in the way we think and in the way we express what we think. For example, one often hears a student or teacher complain that the student knows the "theory" of some subject but cannot effectively solve problems. We should not be surprised: the student has no formal way to learn technique. We expect the student to learn to solve problems by an inefficient process: the student watches the teacher solve a few problems, hoping to abstract the general procedures from the teacher's behavior on particular examples. The student is never given any instructions on how to abstract from examples, nor is the student given any language for expressing what has been learned. It is hard to learn what one cannot express. But now we can express it!* (Sussman, 2005)

Not only can we express "how to" with computers – we can change it! Or at least we're in a better position to try.

As a thought experiment: imagine the distillation of the world's mathematical knowledge into a computer program that could coach students through difficult learning tasks in mathematics in an efficient manner. With a few adaptations, this program might also serve as a creative partner to professional mathematicians. With further adaptations, it may be able to come up with and prove interesting theorems on its own. The development of such a system would certainly constitute a change in mathematical culture. It would also have significant impact on in the way mathematical thinking is applied, in fields ranging from logic to logistics.

In order to move in this direction, one approach is to set aside the AI aspects at first, and focus instead on building a useful collection of *content*. The computer would be used primarily as a communication tool and database. As time goes by, additional sophistication can be added, expressing the user community's collective wisdom about what works and what doesn't. A commons-based peer production system is a suitable *context* for exploring cultural adaptation of this sort. The idea is that a software system created together with its users can be used to build not just a description of mathematical culture, but an actual working model that can serve as an engine for change.

**Theory.** A 6-month pilot study as a participant observer at the Peer-2-Peer University helped develop a general picture of the way learning and adaptation works (and sometimes fails to work) in peer production communities. For example, people often learn computer programming concepts and techniques while building free/open source software and participating in discussions on a developer mailing list. *Paragogy* aims to be a comprehensive theory of peer produced peer learning, and a qualitative complement to Benkler's theory of peer production.

**Tool.** In collaboration with colleagues at in the Knowledge Adaptation and Reasoning for Content (KWARC) group at Jacobs University, PlanetMath's custom code from 2001 was replaced with a new platform built using contemporary technologies. The aim was not just to modernize PlanetMath, but to build a reusable and extensible platform, which we called "Planetary" (Kohlhase et al., 2011). The particular instantiation of this system on PlanetMath is designed to support peer learning according to the paragogical understanding.

**Test.** Launching the Planetary system on PlanetMath constitutes a major change for users. The real-world deployment of the system gave the opportunity to study the response to this change, supported by focus groups and interviews. PlanetMath users provided concrete suggestions on how to extend the software model, which helps build a picture of the way they think about mathematics, and which also contributes to validating the paragogical approach to design, learning, and co-production.

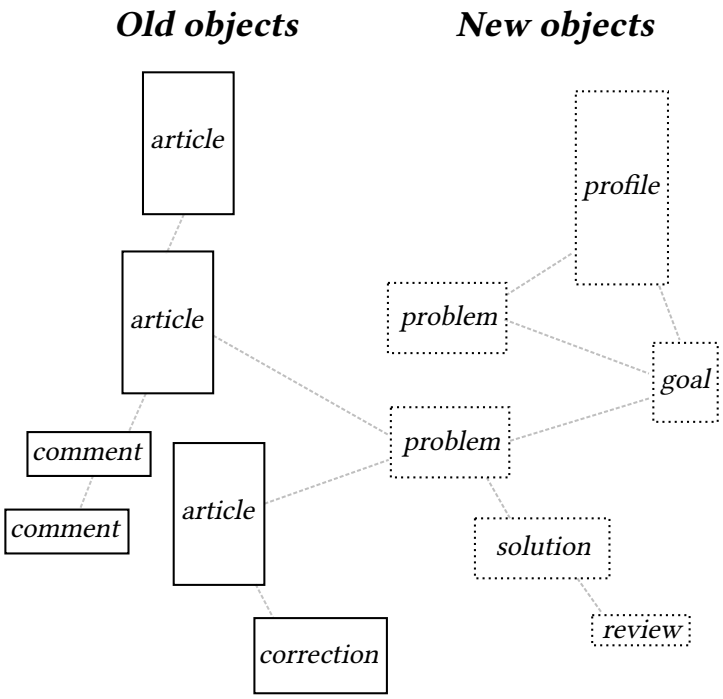

**Figure 1:** *This is the sort of extension we'd like to develop*

## 1.5 Trajectories

**Advances in method and theory.** Using a commons-based peer production system as a way to study and express culture it is an example of the kind of self-conscious experiment with representation found to be lacking by Geertz (1973, fn. p. 19). This approach may be of interest to contemporary cultural anthropologists, who are increasingly involved in participatory research, and fieldwork in networked settings. Paragogy contributes to a broader social science literature, and develops a perspective in which peer production and peer learning are mutually constituting. Although the methods are inspired in part by anthropology and philosophy, the outcome is a new computational account of mathematical collaboration that should prove useful in the design and evaluation of agent-based simulations, as well as online learning environments. The understanding of mathematical social behavior that is developed may be of interest to philosophers of mathematics. These contributions to method and theory are supported by practical advances in learning design and assessment, and provide a framework within which to assess claims about online mediated peer learning, as detailed below. These aspects may be of immediate interest to educators, as well as to education theorists.

**New designs for peer learning.** Gráinne Conole's (2008) perspective on "*learning design*" is that it is best understood as a way to create and represent practice. The design we are using (Figure 1) will include all of the authoring and editorial practices associated with building and maintaining PlanetMath's encyclopedia – and a new layer for problem

solving. The first layer features legacy activities like writing and editing articles, forum discussions, corrections and requests for articles on new topics. The second layer is new, and includes support for setting and solving problems, connecting problems and encyclopedia articles, discussing and reviewing problems, and creating course packets that combine problems with expository texts. From the user's perspective, the environment should offer some significant advantages over a standard textbook or problem archive. For example: nothing is more daunting than being faced with a problem to solve and not knowing what the terms in that problem mean. On PlanetMath, we will be able to provide automatically-generated links to the definitions of technical terms in problem statements. In the event that the linked material is not enough, and the user will be able to make annotations asking help. Answers to these questions will help improve the quality and relevance of the encyclopedia. Over time, we expect a large archive of worked-out examples, heuristics, hints, and strategies to accumulate, helping future users overcome the cold-start problem. Rather than having textbook problems serve as a daunting obstacle to application or research, they should, in this context, serve as stepping stones to relevant and meaningful engagement in mathematical practice.

**A new technique for measuring learning efficacy.** How can we validate claims about learning quality? John Anderson, Lynne Reder, and Herbert Simon advanced a consumer protection perspective on this question.

> *We should make a larger place for responsible experimentation that draws on the available knowledge–it deserves at least as large a place as we now provide for faddish, unsystematic and unassessed informal "experiments" or educational "reforms." We would advocate the creation of a "FEA" on analogy to the FDA which would require well designed clinical trials for every educational "drug" that is introduced into the market place.* (Anderson, Reder, & Simon, 2000)

Techniques for evaluating the efficacy of learning strategies and interventions can also be immediately relevant to users and system designers, in real time. Feedback on learning relevance could help users improve their problem solving skills. Chapter 6 draws on a recently developed approach from computational statistics to address these issues.

**New frontiers for peer produced peer learning.** Partly inspired by the idea of paragogy, Howard Rheingold convened the Peeragogy project,[*,†] which I subsequently joined as a contributing author, and later, editor. Rheingold positions the *Peeragogy Handbook* as "*a resource for any group of people, who want to learn any subject.*"[‡] This thesis will help to refer these claims to sound theoretical and empirical foundations.

## 1.6 Terminology

In cases where it is necessary to distinguish between the "original" PlanetMath built by Aaron Krowne and the "new" PlanetMath developed in the course of this thesis work, I will refer to them as PlanetMath/Noösphere and PlanetMath/Planetary, respectively.

Paragogy is the name for the theory of peer produced peer learning that is developed in this thesis, drawing on earlier collaborative writings with Charles Jeffrey Danoff, and, perhaps confusingly, on contemporary collaborative work in the Peeragogy project. Peeragogy is Howard Rheingold's neologism, adapting my earlier usage, chosen because this term is relatively self-explanatory. What "paragogy" might lack in directness, it makes up in nuance. A term that causes people to stop and think helps problematize the idea of peer learning. The term evokes but also challenges the idiom of the "guide on the side." It is a preexisting word in both English and Greek, so it brings additional associations through its etymology.* There are models of peer learning that remain "*provisionist*" rather than peer produced (Boud & Lee, 2005): in other words, the opportunity for peer learning is provided by some group, and taken up by others. Paragogy comes with a built-in immunity to provisionist thinking. As Chapter 3 explains, the emphasis in paragogy is on co-creating the context in which learning and production take place. The term *peeragogy* is most easily read as a synonym for peer learning. In this document, *Peeragogy* will always refer to the Peeragogy project, and its creations and namesakes (the *Peeragogy Handbook*, Peeragogy patterns, the Peeragogy Accelerator, *etc.*). I use *paragogy* as a shorthand for "the theory and practice of peer produced peer learning."

## 1.7 Related work

The concept of *emergent design* was applied by David Cavallo to create learning environments together with their users (Cavallo, 2000A, 2000B, 2004). Cavallo (2000B) describes his work with Thai villagers to help design local applications for the Logo computer system as "*applied epistemological anthropology*." More recently, this theme was taken up by Cavallo's PhD student, Arnan Sipitakiat (2007), in work with children learning robotics. This practice aims to learn along with research subjects as they build on their existing knowledge and skills, typically in *constructionist* scenarios – in which "*everything* [is to] *be understood by being constructed*" – as opposed to "*instructionist*" scenarios that emphasize teaching (Papert & Harel, 1991).

The idea of emergent design will be connected, in the current work, to the possibility of a "*problematic*" understanding of reality, after Deleuze (1968). Deleuze calls this the philosophy of difference, and it is grounded in his thinking about mathematical dy-

*Greek: *παραγωγή*, meaning "production", "generation"; English: "coaptation", *i.e.* "the adaptation or adjustment of parts to each other", and also "letters added for emphasis or to change the sense of a word."

namics. Building on the associated nexus of philosophical and scientific ideas, Manuel DeLanda (2011) makes a survey of the history of life through a series of computer simulations of dynamical systems, starting with water and ending with pyriamids.

The array of "*man-made information sources for the directive ordering of human conduct*" (Geertz, 1973, p. 251) that are relevant to mathematical practice can be treated with a similar multi-layered computational approach. Much more so than Geertz, the associated idea of *cybernetics* is associated with the work of the anthropologist Gregory Bateson, who insisted on the importance of not separating the "*internal*" and "*external mind*" (Bateson, 1972, p. 470). Ingold continues this line of thought and treats "*organism plus environment*" as a "*developmental system*" (Ingold, 2000, p. 19). Ingold does not talk about development using the language of difference from Bateson and Deleuze but emphasizes *growth* and, especially, *correspondence* (Ingold, 2013, pp. 21, 107). Chapter 4 will draw on Bateson's perspectives on learning.

Economics and organizational theory are almost entirely in the background in the current work: the focus is on phenomena that economists tend to treat as *externalities*. Briefly, one way to deal with externalities this is to create new markets, and another is restructure the firm; both scenarios were examined by Coase (1960, 1937), who emphasized the costs associated with exchange or transformation. Benkler's (2002) idea of commons-based peer production is a third model built around positive externalities that coalesce into new shared resources. Ostrom's (1990) design principles for the governance of common pool resources can be related to Beer's (1979, 1981) Viable System Model, which describes a cybernetic approach to organization.* Paragogy is developed as a parallel framework, focused on the dynamics of learning and adaptation.

Mathematics is usually managed through professional societies, firms, and the guild-like structures of academia. The possibility of managing it in a more "*open*" fashion has been explored by various authors; some, like (Buswell et al., 2004), considering technical issues, others focusing on social engineering (Pitman & Lynch, 2014). To my knowledge there is no prior study on considerations related to learning mathematics the commons-based peer production way. Within the field of mathematics education, most research focuses on classroom settings (Cole, 1998; Cobb, Wood, & Yackel, 1993; Cobb, 1989).

There has been broadly related research on learning in Wikipedia and Wikiversity (Lawler, 2005, 2011), and on learning in free/libre/open source software (Meiszner, 2010). I will draw on the latter in Chapter 4. It is also worth mentioning the traditions of *collaborative learning* (Bruffee, 1984), and *networked learning*.† The latter takes inspiration from Ivan Illich and Christopher Alexander. I draw on Alexander's design pattern methods, connecting them to the idea of emergent design and Deleuze's philosophy.

## 1.8 Summary of the argument

**Part 2 of the thesis describes the research domain.**

I make a case for using a peer production model to build learning resources for mathematics. I also make it clear that PlanetMath needs a new direction if it is to have contemporary relevance. I introduce paragogy through a description of the case study at P2PU in which it developed. The key theme in paragogy is to combine learning at the individual level with contextual change, that is, change in organization or environment. It is a theory of learning and adaptation. I develop paragogy as a framework, which is then used to organize the research literature that is relevant to peer produced peer learning in mathematics. This yields a preliminary set of criteria that can help address the main research question.

**Part 3 describes the research methodology and preliminary studies.**

A key philosophical idea in the thesis is the idea of emergence: the idea that the whole is always more than the sum of its parts. My methodology is rooted in Manuel DeLanda's ideas about emergent dynamics that develop within and across different domains and different levels of analysis (DeLanda, 2006A, 2011). At the micro-level, I develop a statistically-based study of the social antecedents to learning in PlanetMath/Noösphere. This shows how a system like PlanetMath could be used as a research instrument to study patterns of change from a quantitative perspective. I gather ideas about macro-level systemic change from representatives of three important stakeholder groups: students, mathematicians, and researchers who study mathematical practice.

**Part 4 presents the primary results and discussion.**

I describe the implementation of the new Planetary system, which has been built taking the ideas from stakeholders on board. After the system was deployed on PlanetMath, a user evaluation study was conducted. Based on material drawn from interviews with users about their experience with PlanetMath/Planetary, I develop a revised design that better reflects the purposes that users see the site as serving. Finally, I conclude that a paragogical approach to emergent design can be effectively applied within mathematical culture as a way "*to pose the problems set within it and to it by the differential relations it incarnates*" (Deleuze, 1968, p. 235).

# Part 2
# The research domain

# 2 Historical Background

**Could learning mathematics become more like the learning that happens in the course of developing free/open source software?**

## 2.1 The PlanetMath Encyclopedia

### Beginnings

The pre-history of PlanetMath was tied to the fate of a similarly-named website, MathWorld.* Eric Weisstein began collecting the material now found in MathWorld as a high school student, and continued the project as a college student in the late 1980s. "Eric's Treasure Trove of Mathematics," went online in 1995, when Weisstein was a graduate student in astronomy at the California Institute of Technology.†

In November 1998, Weisstein made a deal with the CRC Press to publish his encyclopedia in book format, as the *CRC Concise Encyclopedia of Mathematics* (Weisstein, 2003). One year later, Weisstein accepted the position of Encyclopedist at Wolfram Research, Inc., and the newly-rebranded "MathWorld" site was unveiled in December 1999.‡ In March 2000, CRC Press sued Weisstein and Wolfram Research for copyright violation, forcing MathWorld off of the internet (US Patents Quarterly, 2000). Eric Weisstein was understandably dismayed: "[I]*f you ever assemble a body of knowledge that you want to share with others, you don't want to go through what I have just gone through.*"§

*http://mathworld.wolfram.com

†http://www.echarcha.com/forum/archive/index.php/t-19516.html

‡http://en.wikipedia.org/wiki/Eric_W._Weisstein

§http://www.echarcha.com/forum/archive/index.php/t-19516.html

MathWorld users Nathan Egge and Aaron Krowne, then undergraduates at the Virginia Polytechnic Institute and State University, were also dismayed – and in Autumn, 2000, they devised the idea for PlanetMath: it would be a collaboratively created mathematics reference work that would have resistance to copyright threats built-in, in the form of an open content license.

By Summer 2001, the basic infrastructure for creating an encyclopedia was complete, and a fledgling community had grown up around PlanetMath. It was not alone: Wikipedia also launched that year. Mayo Fuster Morell describes 2001 as a watershed year in the history of online creation communities – the year when the focus spread "*from free software to free culture*" (Morell, 2011).

The CRC lawsuit was settled for an undisclosed sum in late 2001, and on November 6, 2001, MathWorld returned to the internet.* But in the mean time, a new online community had been born – with some very different principles and practices. Whereas MathWorld's terms of use disallow archival copies, PlanetMath regularly published snapshots of the content for download. Moreover, under the terms of the site's license (originally the GNU Free Documentation License, later the Creative Commons Attribution-ShareAlike license)†,‡ users are permitted – and, indeed, encouraged – to copy, mirror, redistribute, print, remix, and reuse PlanetMath content for commercial or other purposes – so long as all such works are published under the same license as PlanetMath, granting downstream users the same rights.

## Stabilization

The key reference on the founding and foundation of PlanetMath is Aaron Krowne's (2003a) Master's thesis, *An Architecture for Collaborative Math and Science Digital Libraries*, written at Virginia Tech under the supervision of Ed Fox. In this thesis, Krowne describes how the early design and development of the site benefited from continuous feedback in the `#math` IRC channel on Undernet.§ He also details the key technical and community features of the site as they developed in this period:

- A state-of-the-art system for displaying mathematical notation on the web, starting from LaTeX sources.
- A flexible authority model that can support both wiki-style articles (that anyone can edit), and a more academic style, where articles are owned by one person, who may, if they wish, grant co-authorship permissions to chosen others, and who

*http://mathworld.wolfram.com/about/faq.html#history
†http://www.gnu.org/licenses/fdl-1.3-faq.html
‡http://creativecommons.org/licenses/by-sa/3.0/us/
§irc://irc.undernet.org/math

must respond to separate commentary from peer reviewers in order to maintain ownership (Krowne & Bazaz, 2004).

- A discussion forum attached to every encyclopedia article, which helps give the resource its "*pedagogical slant*."*
- An autolinking service that helps integrate content into the site, by enabling authors to focus on the contents of one article at a time.
- The Mathematics Subject Classification (MSC) devised by the American Mathematical Society and Zentralblatt MATH provides a hierarchical browsing mechanism.
- A peer review workflow built around a content-level bug reporting feature called "corrections", and user-messaging feature called "watches." The workflow includes a feature whereby articles are "orphaned" if a correction is not responded to after a given period of time. A system for bug reports is particularly important in light of the authority model mentioned above: the historical PlanetMath is *not* an "*encyclopedia anyone can edit*"† in the typical wiki sense.
- "Attachments" expand individual articles with detailed proofs and related expositions.
- A scoring feature provides a rough estimate of how much value each user has contributed to the site.
- Downstream use and modification of PlanetMath's content is permitted, under the terms of the Creative Commons Attribution-Share Alike license (CC-By-SA), a copyleft free content license.

One can readily spot ways in which the core ideas of commons-based peer production – *modularity*, *granularity*, *integration* (Benkler, 2002) – had an influence on the design of the site. Articles are modular and relatively self-contained. Comments and corrections are even more fine-grained than articles. The Mathematics Subject Classification, attachment feature, and autolinking service connect related articles, assisting with integration. Article ownership modularizes control, and provides a protectionary measure for authors that is not given by the content license. Raymondite "homesteading" was built in to PlanetMath's custom software, Noösphere, from the beginning – and the system takes its name from Eric Raymond's (1998) essay.

In 2003, PlanetMath incorporated, and in 2005, obtained non-profit status, so that it could accept tax-deductible donations in the US. Together with a small stream of advertising revenue, donations covered hosting and other maintenance costs since that time.

## Mathematics problems

This section describes my own early involvement with the PlanetMath project.

From 2002-2004, I was enrolled as a graduate student in mathematics at the University of Texas in Austin, and in possession of a large and growing personal collection of tersely-written definitions and proofs related to the department's preliminary exams. For example:

(lebesgue outer measure: fact: lebesgue outer measure is infimum of lebesgue outer measures of open supersets)

1: $X \subset \mathbf{R}^n$

2: $L = \{O \subseteq \mathbf{R}^n : O \supset X\}$

3: $|X|_e = \inf_{O \in L}(\{|O|_e\})$

My name for this collection was the "Austin Problems in Mathematics – Cross-Index", named following the pattern established by *Berkeley Problems in Mathematics* (De Souza & Silva, 2004), and styled APM-Ξ.* In fact, this work had as much to do with the tradition of computer mathematics in the air in Austin as it had to do with exams.

This tradition was embodied in systems and projects like QED (Boyer et al., 1994), Maxima (Joyner, 2006), ACL2 (Kaufmann & Strother Moore, 1996), AM (Lenat, 1976; Lenat & Brown, 1984), Cyc (Lenat, 1995), ISAAC (Novak, 1976; Novak & Bulko, 1993), and KM (Clark & Porter, 1999) among others. Although I was in the mathematics department and not the computer science department, I was quite drawn to this body of work. My notion was to express all of the definitions and theorems relevant to the prelim exams in a symbolic form that could be relatively easily translated into computer code.†

I was convinced that writing down all of the relevant definitions, theorems, and proofs in meticulous detail would effectively guarantee that I would be able pass the exams – even if I wasn't able to build a mathematical artificial intelligence that would pass them on my behalf (or tutor me) in time. "Relevance," to my mind, was determined by

*HTTP://METAMESO.ORG/~JOE/MATH/XI.PDF

†Per HTTP://METAMESO.ORG/~JOE/MATH/100.PDF, the translation of the above example into a more computer-friendly syntax would have been:

```
(defthm leb-outer-measure-inf-over-open-supersets (X)
  (subset X Rn)
  (let ((L (setof (open-subset O Rn) :st (supset O X))))
    (eq (leb-outer-measure X)
        (inf :over O :in L :of (leb-outer-measure O)))))
```

inclusion among the problems and ideas found in old exams – which were available from the department's filing cabinets (without solutions).

I purposefully neglected the fact that the required first year courses were expressly designed to prepare students for *this* year's preliminary exams, which would be written by the instructors for these courses. Accordingly, course homework and in-class exams would have been a better source of material for my cross-index. But here I found myself caught in something of a perfect storm. Compared with my earlier experiences with more tutorial-style instruction as an undergraduate, the almost exclusively lecture-oriented classroom culture was stifling. I had been further spoiled by early participation in collaborative mathematics research. I thought that the instructors were supposed to help me learn mathematics, and indeed, help me to get to the research frontier as quickly as possible; instead, it seemed as if they were putting in effort to make the entire experience as *difficult* as possible. Finally, I was aware that other students would often study for the courses together, but I wasn't sure what to think about this. Was it encouraged? Was it cheating? As it turned out, I wasn't invited, and I didn't invite myself.

Instead, I spent most of my time building my cross-index of old exam material, reading philosophy books, and learning how to program in LISP with support from the contributors to mailing lists related to GNU Emacs, "*the extensible, customizable self-documenting display editor*" (Stallman, 1981). And I thought: why stop with the graduate curriculum? And so the goal shifted: let's build a copyright-free computer simulation of all known mathematics!

It seemed to me that the mathematics community was entirely uninterested in any potentially liberatory aspects of computers. A new project focused on making computer mathematics relevant to human mathematicians – here I was inspired by GNU and Deep Blue – seemed to be the only suitable response. I called this the *Hyperreal Dictionary of Mathematics* project; *cf.* (Baudrillard, 2002).[*,†]

In 2003, I discovered the PlanetMath website and initiated a correspondence with Aaron Krowne about the potential for overlap between PlanetMath and HDM. I admired the fact that he had put together a real, working, system, with actual users. Considering the magnitude of HDM project, I knew it would eventually need a crowdsourcing component. PlanetMath wasn't doing quite what I had in mind, but it seemed like a good place to start. In Autumn of that year, we uploaded the contents of the APM-Ξ into the PlanetMath encyclopedia as world-editable "seed entries".

This was not received particularly favorably by PlanetMath users, which generated a range of useful reflections.[‡] The primary concerns raised by community members were:

[*] HTTP://WIKI.PLANETMATH.ORG/CGI-BIN/WIKI.PL/HDM

[†] Kellner (2007) offers a useful overview of Jean Baudrillard's writing.

[‡] HTTP://WIKI.PLANETMATH.ORG/CGI-BIN/WIKI.PL/ONE_WEEK_IN_OCTOBER

(1) The entries could not be understood without reading an accompanying FAQ, and were not "human readable";

(2) A casual visitor to the PlanetMath website might get the wrong impression about the nature of the encyclopedia when looking at the owned by the user apmxi; and,

(3) Nearly 600 entries had been introduced into PlanetMath by the site's administrator in one big batch, circumventing, at least in outward appearances, the site's usual model of careful review and collaborative editing of entries.

Subsequent to a poll, it was decided that the entries owned by apmxi would be "orphaned," and any that were not adopted by community members after a week would be deleted from the encyclopedia. This was the fate that befell most.

It was clear in hindsight that the APM-Ξ material – independent of its potential value for computer mathematics – was *not* something that had a positive value for most people in the PlanetMath user community. Although it was something of a personal embarassment, the apmxi incident was a testament to the strength of PlanetMath's norms, and it illustrated the role that shared norms play in maintaining an integrated common resource. It also showed that the specific affordances of computer technology, for instance, for bulk processing, or for using hypertextual methods to present alternate treatments of a given topic, would need to be used and developed carefully, so as to work well for the *people* involved.

As could have been expected, over the next year, things ground slowly to a halt for me in Texas. With no prelim exam success, I was transferred into the Master's program, and given the opportunity to work with the mathematician and computer scientist Robert Boyer, but he and I couldn't see eye to eye about a thesis topic. At the end of Autumn in 2004, I was formally asked to leave.

Although I had been an errant and irresponsible mathematics graduate student, I had assembled another identity along the way: that of a necessarily interdisciplinary researcher working on understanding and transforming mathematical culture. Although PlanetMath was in many respects "marginal" to mainstream mathematics, and my project was on the fringes even of PlanetMath, this was a digital library – where the margin was perhaps not such a bad place to be.*

*In connection with the idea of "*math for the people, by the people*", is worth pointing out that Arendtian *constituent moments* "*enact felicitous claims to speak in the people's name, even though those claims explicitly break from the authorized procedures or norms for representing the popular voice*", *cf.* (Frank, 2009, p. 210).

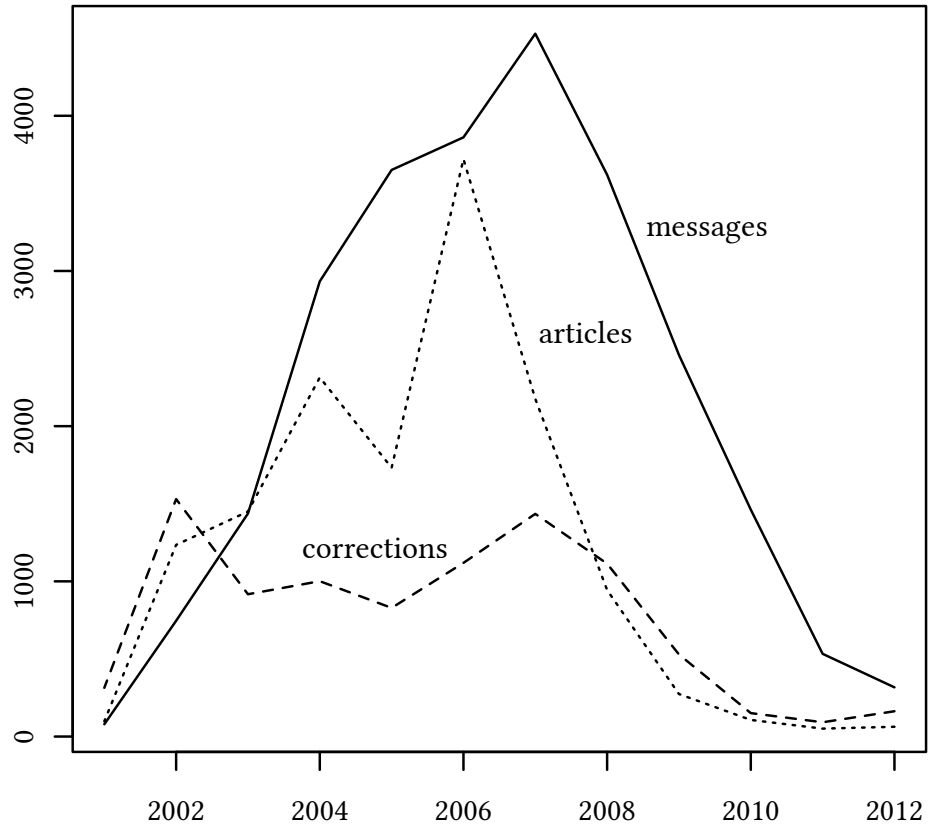

**Figure 2:** *Plot showing the number of messages, articles, and corrections added to PlanetMath over the last decade*

## Reach and scope

Since PlanetMath describes itself with the by-line "by the people, for the people," one way to assess its quality, success, and vitality is through data on user participation. As an initial foray, Figure 2 shows the contributions per year in various sectors of the site. As is typical for online communities, contributions are uneven, and roughly follow a "power law" distribution, *i.e.* $f(x) = ax^k$. The relevant exponent is approximately $-4$, which represents a much steeper dropoff than popularity on the internet ($\approx -3$), energy efficiency of scale for living organisms ($\approx -2$), or word frequencies in natural language texts ($\approx -1$); *cf.* (Corneli, 2011).

PlanetMath can also be evaluated as an encyclopedia. A brief summary, following the framework used by Emma Previato (2004) in her review of the *CRC Concise Encyclopedia of Mathematics* (Weisstein, 2003), gives a look at how PlanetMath measures up (Table 1).

| | |
|---|---|
| **Coverage** | The median entry would be an advanced undergraduate or beginning graduate topic. PlanetMath is generally considered to have more in-depth treatment of technical issues, e.g. of proofs, than that found in Wikipedia. Over 15000 terms are defined in over 9000 articles. |
| **References** | Present in many articles, although there is not yet a unified database of references or style of presenting them (this is planned). |
| **History** | 600 items, mostly 20$^{th}$ Century or later (HTTP://PLANETMATH.ORG/MSC_BROWSER/01Axx) |
| **Audience** | Consistent with the coverage, there have been 4127 posts in the "Graduate/Advanced" forum, 4261 posts in the "University/Tertiary" forum, and 1199 posts in the "High School/Secondary" forum. |
| **Clarity** | There is no hard and fast rule. Some articles will tend to be minimalistic, but precise (particularly when the authors have English as a second language). Other articles even from native speakers may be verbose and vague. In any case, debates over clarity of presentation are intense, and a high standard is maintained. |
| **Pictures** | There are over 600 images, but since this is only about 7% of the number of articles, the prevalence could be improved. A unified database/gallery of pictures would help. |
| **Accuracy** | At the time of this writing there are 48 outstanding corrections; more than 14080 corrections have been filed since the site began, though 2337 are classified as "addenda", meaning that no mistake is implied, and 9182 are classified as "meta/minor", which suggests that in the entire history of PlanetMath some 2561 real errors have been found through the peer review process (and all but a few fixed!). Note that these numbers do not take into account changes initiated by authors without prompting, and would tend to under-represent error fixing in world-editable articles. |
| **Unusual** | PlanetMath provides "math for the people, by the people". |
| **Weight** | PlanetMath can be comfortably edited from a lightweight laptop weighing about 1kg (and browsed from a mobile device weighing considerably less). |

**Table 1:** *Succinct review of the PlanetMath Encyclopedia*

The dropoff in participation in recent years is presumably due to a mixture of factors: saturation of the encyclopedia, technical problems with the site's software, and the rise of successful competition. Most notable among the "competitiors" are two other sites, Wikipedia and StackExchange, both using the same license as PlanetMath.*,† It is clear from Figure 2 that PlanetMath will need a new approach if it is going to continue to be a productive community.‡

As Sophia Angeletou et al. write:

> *Health of online communities is a relatively new and complex concept that is codependent on the emergence and evolution of user behaviour in those communities.*
> (Angeletou, Rowe, & Alani, 2011)

## 2.2 The broader context: Other candidate solutions

There are already several *gratis* (and some *libre*), well-established players in the open/online mathematics learning space. In addition to Wikipedia and StackExchange, mentioned above, other relevant service providers include MITx, Coursera, OCW, edX, Stanford, Khan Academy, PurpleMath.com, OpenStudy.com, and functionspace.org. On offer are articles, Q&A forums, courses and course materials, problem sets and videos, as well as peer support in various forms.

For now, through it's economy of scale, Wikipedia is dominating in the encyclopedist prosumer market; *cf.* (Jankowski, 2013). After more than a decade of work, PlanetMath is valuable as a highly curated topic-specific reference resource, but Wikipedia is more active. It also seems to define many more mathematics terms than PlanetMath, although a structured comparison of coverage is still being charted.§ Perhaps surprisingly, even Wikipedia is less active than it once was (Simonite, 2013), and there appear to be bigger patterns at work, with social media on the rise, while centralized peer production sites are less used.

Could PlanetMath have any technical, or ethical, advantage (Landini, 2012) over existing technical innovations like Wikipedia, Massive Open Online Courses (MOOCs), Q&A sites like StackExchange, and videos collections and problem sets like the ones produced by Salman Khan and his colleagues? Is there already an adequate answer to the demand

*"*There are approximately 29,280 mathematics articles in Wikipedia,*" from HTTP://EN.WIKIPEDIA.ORG/WIKI/PORTAL:MATHEMATICS

†As of June 16, 2013, math.stackexchange.com and MathOverflow contain 147768 and 42735 questions, respectively.

‡Note that hundreds of PlanetMath articles have been used as seed material for world-editable articles in Wikipedia, under the auspices of the (somewhat inaccurately named) "PlanetMath Exchange". HTTP://EN.WIKIPEDIA.ORG/WIKI/WIKIPEDIA:WIKIPROJECT_MATHEMATICS/PLANETMATH_EXCHANGE

§Deyan Ginev, personal communication

for high-quality, low-cost, globally accessible, mathematics instruction? This brief discussion focuses particularly on comparisons with Khan Academy.

Khan Academy,[*] founded by Salman Khan in 2006, is built around a collection of instructional videos hosted on YouTube, which are supplemented with work-book style exercises, mostly for school-level topics.[†] It was initially best known for mathematics content, although more recently, it has added content in a range of other fields.

Khan Academy has helped to popularize the "flipped classroom" model, in which lectures are viewed out of class, and homework is assigned to be done in class (Khan, 2012). The key thought behind this model is that teachers can help students who are struggling, or use class time to invite students to help one another. Adopting a flipped classroom model for graduate-level mathematics would have helped address my discontents at UT Austin, since in-class discussion would have replaced note taking as the norm.

However, Khan Academy and most current MOOCs still have a highly-centralized production model, whereas PlanetMath's content is entirely user-built. Khan Academy's application of the non-free Creative Commons Attribution-NonCommercial-ShareAlike license (CC-By-NC-SA) reflects their centralized stance.[‡,§]

PlanetMath can continue to grow in a comparatively demand-driven and participatory manner, which facilitates the development of advanced material and detailed expositions. To use Landini's (2012) term, PlanetMath is considerably more "*malleable*" than Khan Academy and most MOOCs. Public wikis provide another relatively malleable alternative – but they are most malleable at the content level. In fields like sociology, it makes good sense to invite students to author or edit encyclopedia articles as part of the learning process (Konieczny, 2007). It is hard to imagine a mathematical curriculum that did not focus on problem solving. A customized version of a mainstream content management system, together with robust support for LaTeX, makes Planetary at least as flexible a typical wiki, and can help build additional workflows.

While a centralized production model makes a great deal of sense for a resource with highly integrated content (like a course), a distributed production model makes more sense when building a resource that is relatively disaggregated (like a Q&A collection). PlanetMath/Planetary allows for both disaggregated one-off questions and answers, and more cohesive textbook or course-like exposition – and it seeks to link these two models together. As with Khan Academy, the new PlanetMath content should be useful for self study, which may facilitate more efficient use of in-person interactions. And like MOOCs, PlanetMath should also simultaneously open up new avenues for peer support

[*] http://www.khanacademy.org/

[§] http://freedomdefined.org/Licenses/NC

online. Unlike these more centralized models, PlanetMath is oriented around end-user co-production of structure, preferring an "emergentist" approach to what Boud and Lee (2005) would call the "*provisionist*" approach.

In the first place the question is not whether this approach is "better," but what it may possibly be better for. I would argue that an emergentist strategy is better for working with advanced content. Only relatively well-understood content can be developed locally, for any given locale. This suggests a deeper point, which does indeed take on an ethical dimension. In short, we should eschew provisionist approaches to mathematics on the basis of Euclid's assertion that *there is no royal road to geometry*. Even if we managed to build an computer tutor that delivered superb personalized instruction, and which made learning what we currently think of as difficult mathematics fairly easy, this too should ultimately be surpassed. That would be, as ever, a lot of work. The most important insights would surely come from the system's users.

The fact that the courses and lectures provided as part of mainstream mathematics are good enough "for most people" is not a real counterargument, since, in the first place, most people have never set foot in an advanced mathematics classroom, and secondly, we don't yet know how effective an alternative emergentist approach would be. Existing educational research suggests that if they were available, personalized tutorials would be more effective than classrooms (Bloom, 1984). Unless there was compelling evidence to show that an emergent peer learning approach was either ineffective, or otherwise impractical, it seems vital to give it a serious try, at least on an experimental, demonstation, basis.* Emergence, here, does not mean adding more and more elements to a loose network of associations and expecting meaning to appear, and neither does it at entail giving up on training as such. Rather, it is a question of establishing a suitable *ethos*, as a higher-order constraint on behavior; *cf.* (Sloterdijk, 2013, pp. 162–163), (Deacon, 2003). Once this is done, the corresponding ethical argument is no longer needed: the point will have become, as mathematicians like to say, obvious (Cooksey, 2005, p. 3).

## 2.3 The road ahead

Although it has experienced both a rise and a fall, PlanetMath/Noösphere was reasonably successful as an online community: the software stabilized early on and has required little upkeep, while the site continued to grow. The downside of early stabilization is that relatively few new features were developed since the early 2000s. The sign that there might be a problem – and some unrealized potential – was that feature

*Research mathematics already has many of the features typical of peer production, and the standards for openness in modern mathematics tend to go beyond those in many other academic fields. For instance, Article 2 of the WIPO Copyright Treaty holds that mathematical concepts, per se, are not copyrightable. Mathematical expressions may be further excepted by the legal notion of *scènes à faire*.

requests kept coming in, while very little new code was being written.* Despite these concerns, there is still an active interest in the project nearly a decade and a half after its creation.

Figure 3 presents a use case for PlanetMath that inspires the technical work carried out in support of this thesis. The diagnostic features described in the use case were not realized, although in light of the new semantic features that are included in Planetary, they may not be far off. Certainly they would not require a mathematical "Deep Blue".

As with flipped classrooms, had a system like this existed in 2003, I would have been a very happy user, and contributor. My basic concern at the time was: couldn't learning mathematics be done the same way I was learning LISP? There was detailed documentation available in Emacs, together with the full source code, a Read-Eval-Print Loop (REPL) for trying things out, and an integrated debugger. If I ran into questions that I couldn't resolve on my own using these resources, there were public mailing lists with participants who were always glad to help me, and to suggest improvements to any new packages I might upload. Although much remains to be done, PlanetMath/Planetary should eventually support this style of learning in mathematics.

Indeed, the renewed activity in software development is based on a redesign, not just a rebuild. PlanetMath/Planetary puts more emphasis on content reuse, and, being using a mainstream content management system, makes the system better suited than Noösphere was to support ongoing development. In a philosophical sense, PlanetMath represents a new and distinct type of encyclopedia, and it is now poised to begin its final ascent to the literal classical meaning of *ἐγκύκλιος παιδεία* ("recurrent instruction"). Because the technology that supports the site is special-purpose (and is not constrained to be "a wiki"), it can helped zero in on the specific set of features that support commons-based peer production – and now peer learning – in mathematics.

## 2.4 Summary

From a development standpoint, this is an critical moment, since there are mature, extensible, web frameworks available, together with a relevant collection of content, together with a clear demand for a new approach. As a researcher, this is interesting, because it affords the opportunity to examine technological change as an insider in the process. At the same time, PlanetMath occupies a novel position: although it is host to various examples of mathematical practice, it is still outside of the mathematical mainstream. It is useful as vantage point from which to survey and reflect on mathematics as a whole.

*http://wiki.planetmath.org/cgi-bin/wiki.pl/Feature_Requests

***Primary Actor***: A student, Madeleine, who is trying to learn multivariable calculus.

***Main Success Scenario***:

1. Madeleine is enrolled in an advanced calculus course at university. She learns about PlanetMath from her instructor who recommends it as a place for extra practice with homework problems. Madeleine creates an account, fills in basic profile information, and starts solving problems that the system supplies based on the information she added.

2. The problems that the system supplies are automatically linked to reference resources in PlanetMath's encyclopedia. This expository material gives Madeleine easy access to the relevant mathematical concepts, examples, and hints needed for solving the increasingly difficult practice problems. However, she eventually runs into a problem where neither the automatically supplied information, nor her current knowledge of the subject, is sufficient. She's completely stuck on a problem having to do with water flow in a pipe! Madeleine attaches a help request to the problem: "I understand that I have to use the two variables $x$ and $y$ to solve for water flow, but I don't understand what the boundary limits of the equations would be: do I have to convert it to polar coordinates?"

3. This request is noticed by Natalie, a mathematics graduate student who regularly looks at the feed showing "recent requests for help with advanced calculus." She sees that the reference resources linked to Madeleine's problem are probably not sufficient, and that Madeleine's idea about using polar coordinates would work. Natalie makes some changes to the encyclopedia indicating that converting to converting to polar coordinates can be necessary in pipe flow problems, and sketches an example. Natalie then checks that this information links to Madeleine's problem correctly, and alerts Madeleine to the changes. With this new information, Madeleine is not only able to solve her problem, but can proceed with confidence: she had the right idea after all!

**Figure 3:** *An example use case for problem solving support on PlanetMath*

Although there are other platforms that people can use to discuss problems, none of them clearly present the opportunity to make something that is better than a textbook from the point of view of learning, cohesion, and exposition. Considering the difficulty of managing advanced material and personalizing the learning experience, I make the case for using a somewhat distributed peer production model, rather than a centralized provisionist model. Although there are many great textbooks, and great teachers, we don't yet know whether the computer, or computer mediated communication, can deliver comparable (or complementary) results. The kind of research that is developed in thesis is needed in order to make that research possible.

This project builds on a decade of experience with the PlanetMath community. In this chapter, I have highlighted some of the problematic aspects that experience. I came to the project with the view that mathematics itself is already a kind of simulation, even if mostly still carried out on paper and with chalk – and, indeed, already a kind of virtual community, even if most of its activities take place offline and in person. My philosophy at the time was "*To simulation we reply by simulation*" (Baudrillard, 1983, p. 87); these days, it's closer to "*What it is is up to us*" (Rheingold, 2000, p. 39). This applies to PlanetMath, certainly, and may apply to mathematics more broadly, if we're willing to tackle some problems that aren't drawn from filing cabinets (Deleuze, 1966, p. 15). To supplement my participant observer perspective on these matters, I've presented some figures on participation drawn from the PlanetMath database, which confirm the need for a change in direction if the PlanetMath project is to continue in an active form.

# 3 Theoretical Background

**Theories of pedagogy can help us "*get to the root of conditioning through practising repetitions*" (Sloterdijk, 2013, p. 199) – but they fail to model the productive, explicating, way in which learning unfolds in online peer production communities. These features are better described with the new-old word, *paragogy* (from *παραγωγή*, production).**

## 3.1 Paragogy

The term *paragogy* (literally, "para-" alongside, "-gogy" leading) is used here to characterize the critical study and practice of peer produced peer learning, adapting the classical concept of *pedagogy* and the relatively recent notion of *andragogy* (Knowles, 1968) to a peer learning context. The need for a theory of this nature was articulated in dialog and collaborative research with Charles Jeffrey Danoff (Corneli & Danoff, 2011a, 2011b). Having first met in person at Wikimania 2010, and then again online at P2PU where we were preparing to become course facilitators, we agreed to enroll in one another's first round of courses and share feedback. P2PU aims to provide a social layer that is not supplied by default with Open Educational Resources,* and our agreement presented us with another small scale social context within P2PU. Paragogy was developed in Danoff's *Collaborative Lesson Planning* course, as we tried to understand why my *DIY Math* course had gone so badly (see Appendix A for the course description and post mortem). We used paragogy to examine a range of courses and support experiences at P2PU. After describing this analysis, the chapter concludes with a discussion of paragogy as a unified perspective on individual and contextual change.

*http://www.shuttleworthfoundation.org/projects/p2pu/

## DIY Math

During Autumn of 2010, I made a brief and fairly naive effort to run a discussion-based online mathematics course at P2PU called "*DIY Math*", with the hope that participants would self-organize a suitable peer-learning structure. My motivation for running the course was partly to experiment with peer learning and self-organizing structures in mathematics. At the same time, I was also interested in exploring possible organizational connections with P2PU, where I hoped PlanetMath might eventually come to play the role of a mathematics department. Table 2, drawing on a broader discussion of roles in education from (Corneli & Mikroyannidis, 2012), applies a framework from Ken Wilber (1997) to summarize the overall picture.

When *DIY Math* actually ran, participants quickly lost interest, and all participation stopped after two weeks.* Although this was clearly a failed experiment from a teaching perspective, it is actually quite useful as a baseline reading for the broader project of understanding peer produced peer learning. The experiment shows what happens in a learning project where there is essentially no structure provided at the outset.

The rapid failure of *DIY Math* provoked a certain amount of self-criticism, but it also led me to ask the following critical questions about the learning context at P2PU:

- *What if P2PU was taking an ongoing survey of the "wished for" course topics?* Then a future course organizer would be able to create courses specifically tailored to the interests of self-selected participants.
- *What if every participant specified their level of commitment in advance?* Building a "contract" with the facilitator – and with the community – would help ensure that people would be make appropriate commitments (and keep them).
- *What if facilitators themselves got more coaching and peer support?* Ongoing discussions in the P2PU community mailing list helped a little, but not enough. Quality control was sacrificed to free experimentation. However, it was not entirely clear how a shared knowledge base about "what works" would develop out of the individual experiments.

More than the bare-minimum structure will be needed for peer learning in mathematics to succeed. The next term, after polling people about their interests, I ran a second more traditionally structured and focused course ("*Math for Game Designers*"), with a detailed syllabus prepared in advance, and this course did not go much better in terms of student participation than *DIY Math*. Again, this suggests that it is not simply more structure but the *right* structure that is needed.

| | |
|---|---|
| | ***An "ideal" participant in the DIY Math course:*** |
| **I** | say what I want to study |
| **We** | talk about difficulties and successes |
| **Its** | discussions on a shared mailing list |
| **It** | helps me learn mathematics (and improve my skills at being a self-directed and peer-to-peer learner) |
| | ***A P2PU course facilitator:*** |
| **I** | come up with a course I'd like to facilitate, and then facilitate it |
| **We** | discuss ideas about how our courses might work and what "facilitation" means (e.g. as opposed to "teaching") |
| **Its** | discussions on a community mailing list and other settings (including discussions with participants in the course as it runs) |
| **It** | helps me improve my skills at a course designer and facilitator (and it's fun talking about and practicing this stuff!) |
| | ***An a posteriori picture of a DIY Math participant:*** |
| **I** | try to figure out what to study |
| **We** | sometimes give or get advice that isn't always so helpful (and most of it isn't for me, anyway) |
| **Its** | a bunch of good intentions that lead nowhere |
| **It** | confirms my sense of the difficulty of learning anything in a self-directed fashion (and the difficulty of mathematics in particular) |

**Table 2:** *Roles surrounding the* DIY Math *course at P2PU*

## Paragogy principles

I devised and shared five "paragogical principles" with Danoff's *Collaborative Lesson Planning* course, where they were jointly revised. I chose andragogy (Knowles, 1968) as a starting point for adaptation, knowing that since andragogy is a theory of *adult education*, and the aim was a new theory of *peer learning*, serious alterations would need to be made. I made use of Laurie Blondy's (2007) critique, which shows that the following major assumptions of andragogy often fail in online mediated learning applications.

1. **That adult learners are self-directed.**
2. **That they bring a wealth of experience to the educational setting.**
3. **That they enter educational settings ready to learn.**
4. **That they are problem-centered in their learning.**
5. **That they are best motivated by internal factors.**

A paragogical view suggests that everyone has a mixture of self-directed, other-directed, dependent, and independent, behaviors, without saying that any of this is good or bad. It suggests that a particular sort of self-concept may be less important than a robust concept of "*shared context in motion*," which constrains but is also shaped by behavior, as per Kitaro Nishida; *cf.* (Abe, 1988). It emphasizes social intelligence over so-called "mental age," and focuses on social dynamics rather than individuals.*

A paragogical view says that, whatever our past experiences may be, we have a lot to learn about learning. In order to show why, it is again helpful to translate the key term: "*Μάθησις means learning; μαθήματα, what is learnable*" (Heidegger, 1977). On the strong etymological view, mathematics is the study of things insofar as they are learnable, and what makes something learnable is exactly what makes it mathematical. For Heidegger, this is the axiomatic. Deleuze uses a related but less logistic conception: the problematic. "*Learning is the appropriate name for the subjective acts carried out when one is confronted with the objecticity of a problem*" (Deleuze, 1968, p. 204); problems are themselves constituted in a supple and always "*meta-mathematical*" dialectic, understood to be "*a system of differential relations between genetic elements*" (Deleuze, 1968, pp. 203, 229).

At the same time, from a paragogical perspective, learning is not an automatic default; it is a specific sort of highly conditioned side-effect. One may be stuck in a rut. A *peer* should not be conceptualized as someone who is stuck in the same rut. Rather, people who learn together or from one another, who help one another get a better grasp of the world, are understood to be "peers."

The paragogue often has an application in mind, but learning "*always takes place in and through the unconscious*" (Deleuze, 1968, p. 204), and one problem leads to others. "*Learning to swim or learning a foreign language* [...] *tears us apart but also propels us into a hitherto unknown and unheard-of world of problems*" (Deleuze, 1968, p. 241).

Finally, realizing a motivation seems at least as important as its existence in the first place. Merely indicating that a given motivation is "internal" or "external" is not particularly incisive. More can be learned by realizing motivations where this is possible, then going on to the next thing.

*Après* andragogy, then, these are the five paragogical principles:

1. **Changing context as a decentered center.**
2. **Meta-learning as a font of knowledge.**
3. **Peers provide feedback that wouldn't be there otherwise.**
4. **Learning is distributed and nonlinear.**
5. **Realize the dream if you can, then wake up!**

* *Cf.* Eugene Matusov [§1.1, p. 3].

It should be elucidating to mention straight away that the new five-point framework can be understood as an extension of "I/We/Its/It" from the previous section. In these terms, the framework amounts to "Context/I/We/Its/It". Whereas andragogy deals with what Manuel DeLanda would call "*tendencies*," paragogy deals with – necessarily contextual – "*capacities*."

> *While tendencies make a list of essential properties look falsely permanent capacities explode it since for a given whole it would be impossible to list all the different ways in which it can affect and be affected by innumerable other wholes.*
>
> (DeLanda, 2011, p. 186)

Nonaka and Takeuchi (1995) drew on Nishida's thinking to build the SECI model of knowledge production.* This model has close parallels with Ken Wilber's (1997) "I/We/Its/It". It is curious that neither of these frameworks makes an explicit place for context, although Nonaka and Takeuchi would likely agree with Gregory Bateson that the key point is that "[i]*t is the context which evolves*" (Bateson, 1972, p. 164). In a more detailed interpretation, "Context" could be decomposed into nested, overlapping, or adjacent contexts. Context, thought of as an "*environment*," plays an important role in *constructivist* thinking and learning design:

> *Thinking of instruction as an environment gives emphasis to the 'place' or 'space' where learning occurs. At a minimum, a learning environment contains: (1) the learner; (2) a 'setting' or a 'space' wherein the learner acts, using tools and devices, collecting and interpreting information, interacting perhaps with others, etc.*
>
> (Wilson, 1996, p. 4)

Again, in the paragogical view, the environment is not thought of as simply "given."

> *Interactions observed in complex ecosystems need not be regarded as expressing self-organizing properties of the systems themselves; instead they can be understood as the consequences of the various and variable adaptive strategies of individual organisms living together in restricted spaces.* (Vayda & McCay, 1975)

Andrew Vayda and Bonnie McCay position adaptivity within a "*neo-Darwinian selection theory*," in which life is subject to various "*hazards*."

> *Important here is the notion of* ***process*** *of response, including processes whereby the unit of action may shift from individuals to various forms (and degrees of inclusiveness) of groups and perhaps back to individuals, in accord with the magnitude, persistence, and other characteristics of the hazards in question.*
>
> (Vayda & McCay, 1975), original emphasis

*SECI stands for *Socialization/Externalization/Combination/Internalization.*

The notion of *process* underscores to the critical importance of a context in which that process can unfold.*

Within the field of education, Marlene Scardamalia's notion of "*collective cognitive responsibility*" (Scardamalia, 2002) is sympathetic, although it remains basically provisionist. Her claim is that in the standard classroom model, "*all the higher-level control of the discourse is exercised by the teacher.*" Students are "*reactive*" and "*receptive*," their work focused on "*tasks and activities.*" Small groups and decentralized, constructive, computer mediated communication are seen as two possible alternatives that "*turn more responsibility over to the students.*"

## 3.2 P2PU: An "After Action Review"

The paragogy principles are intended to serve as guidelines for building successful peer learning experiences. Corneli and Danoff (2011A) looked at how each of principles was (or was not) implemented at P2PU. A summary of this analysis is presented below. In addition to the paragogy principles, the US Army's (2002) After Action Review (AAR) provided the basic technology for *doing* paragogy. The AAR's intended purpose is to "*identify strengths and shortcomings in unit planning, preparation, and execution, and guide leaders to accept responsibility for shortcomings and produce a fix.*" It places much more emphasis on learning at the group level than the corresponding basic technology of andragogy described in (Carlson, 1989). Although the context of application is different, there are parallels between the AAR and the Action Research cycle; *cf.* (Carr & Kemmis, 2003; Lawler, 2008). The four steps in the AAR are:

1. *Review what was supposed to happen (training plans).*
2. *Establish what happened.*
3. *Determine what was right or wrong with what happened.*
4. *Determine how the task should be done differently the next time.*

(US Army, 2002)

**Changing context as a decentered center: Mapping system dynamics and semantics** We organized multiple courses where participants were supposed to interact and learn about the subject matter: *Collaborative Lesson Planning* Fall 2010 and Winter 2011 (co-organized by Charles Jeffrey Danoff and Dr. Majorie King); *DIY Math* (Fall 2010), and *Math for Game Designers* (Winter 2011) by Joseph Corneli; *Open Governance and Learning* (co-organized by Corneli and Marisa Ponti); and, in Spring 2011, *Shaping P2PU*,† which was an "intervention" based on a preliminary version of the paragogical evaluation presented here. Due to critically low participation, the mathematics courses did

* *Cf.* Eugene Matusov [§1.1, p. 3] and Tim Ingold [§1.3, p. 7].

† HTTP://NEW.P2PU.ORG/EN/GROUPS/P2PU-THE-COURSE/

not run to completion. Participation in *Collaborative Lesson Planning* and in *Open Governance and Learning* was minimal, but sufficient for a conversation to be sustained for the entire 6 week session. The theory of paragogy was born in these discussions. More than 30 people signed up for *Shaping P2PU*, but participation was very low. These experiences were typical: participation within courses was globally uneven, and falling over time. Our best experiences as course organizers happened when we were committed to working through the material ourselves. Combining facilitator dedication with gentle prompts to participants to follow through on their commitments could go a long way towards keeping engagement at a reasonable level, but this only works when commitments are somewhat clear in the first place. The case of *Shaping P2PU* shows that organizer commitment is not enough. The P2PU ecology contains an implicit rubric for learning and engagement: from the time a member signs up for a course, to its completion, peers go through a cycle.* P2PU could implement more formal check points throughout the cycle, requiring participants to specify, reaffirm, or adapt their commitments in relationship to judgments about quality. The AAR could be useful in this regard.

**Meta-learning as a font of knowledge: Transparency, accountability, and tone** Support for facilitators was offered as a P2PU course (*Course Design Orientation*), in mailing lists, via weekly phone calls, in a Q&A issue tracker, and via other informal channels. Participants in courses were presumed to be ready and willing to contribute in a useful fashion. The core members of P2PU are doing a lot of work, and the project is moving forward, with grant funding, incorporation, and several new staff positions. However, apart from contractual agreements within the nonprofit and basic standards for etiquette, participants have little or no accountability to one another. The P2PU governance model was said to be based on "*rough consensus*," after MIT professor David Clark's description of the Internet Engineering Task Force at the July 1992 IETF conference: "*We reject: kings, presidents and voting. We believe in: rough consensus and running code.*"† Pursuant to this, it would be helpful if a concise discussion of the current consensus norms and "best practices" for organizers and participants could be made available. The current *Course Design Handbook* provides one starting point, but it would represent a better consensus if it was improved by capturing insights from successful and less successful courses.‡ This sort of resource would be particularly useful for newcomers and to people who cannot regularly attend the community telephone calls.

**Peers provide feedback that wouldn't be there otherwise: Dealing with problems in a respectful way** Discussions about P2PU happen in the community mailing list and other places mentioned above. At the time when we were doing this research,

*https://wiki.mozilla.org/Drumbeat/SoW-engagement-ladder

†http://www.wired.com/wired/archive/3.10/ietf_pr.html

‡http://wiki.p2pu.org/w/page/27905271/Course-Design-Handbook

bug reports and feature requests related to the software were supposed to go into an issue tracker hosted on Lighthouse.* Discussions about P2PU also happen in courses, where they may be viewed as distractions from the content of the course. Even within the mailing list, it can be difficult to keep track of the full range of ideas circulating at any given time. And, apart from development work, it can often be hard to tell what's happening around P2PU. Presumably participants who have identified critical and unsolvable problems simply leave. The Q&A tracker† and mailing list both provide ways to build factual knowledge, but seem less effective for building *strategic* knowledge. Broadly, we would like to have had more clarity about how to contribute to the process of shaping P2PU.

**Learning is distributed and nonlinear: Design considerations** Facilitators are supposed to choose and assemble suitable learning resources for their courses (blogs, OER, etc.), in which everyone is supposed to learn something. In our experience, this is essentially what happened, but it is hard to measure when, whether, and how much knowledge was gained. Dealing effectively with complexity is hard, and more attention to modeling the learning process could help. However, it is not clear how or whether the data model used by P2PU's current platform – based on shared activity streams drawn from around the web – relates in a significant way to *learning*. It seems that P2PU would have to work hard in order to be able to use anything but "participation" as a proxy measure for learning. In terms of broader issues of quality control, one suggestion would be for P2PU core members – including staff – to start using the P2PU platform to organize their activities in the open, sharing what they are learning in the process of working on the site.

**Realize the dream if you can, then wake up: High level roadmap** At one time, the high-level vision at P2PU was arguably a Declaration of Independence from Formal Education.‡ But arguably each participant has their own vision, and their aims are often much less radical.§ When we were building this analysis, P2PU had recently had its first board meeting, but, so far, documentation about the organization's vision and roadmap have not been presented to or affirmed by the user community – nor has the user community presented any stipulations to the organization. P2PU has made considerable progress (e.g. in the form of successful grant applications), but without more transparency about these efforts, the ability of non-core members to learn from organizational successes is limited. In order to maximize the possibilities for others to contribute, P2PU should work on a public roadmap that leads from now up to the point where the vision is achieved. Both vision and roadmap should be revised as needed.

## 3.3 Paragogical praxis

The study at P2PU helped develop a notion of "principled paragogy" – an essentially normative theory. These principles can be re-evaluated to set the stage for "emergent paragogy" – a descriptive theory. The paragogy principles point to five specific kinds of change that actions within a learning context can accomplish (Corneli & Mikroyannidis, 2011). These five points express the paragogical principles in a more uniform way.

1. **Changing the nature of the space** : $\Delta$ *context*
2. **Changing what I know about myself** : $\Delta$ *metalearning*
3. **Changing my perspective** : $\Delta$ *feedback*
4. **Changing content or connectivity** : $\Delta$ *distributivity*
5. **Changing objectives** : $\Delta$ *achievement*

If change is a "*quintessential element*" in learning (Burger & Starbird, 2012), it makes sense to give it a central role in learning design. The question "what changed?" provides a unified lens through which to examine and evaluate problem solving heuristics, like Pólya's (1945), as well as more open-ended problem solving processes, like those outlined by Schoenfeld [§1.3, p. 9]. Chapter 7 will use these five dimensions of change to understand user requirements for new problem solving support in PlanetMath/Planetary. Paragogy is a theory of peer learning in which the learner is not a separate species. With this in mind, the five paragogy principles can also be translated into practical suggestions on how to be an effective paragogue (Corneli, 2012). The following points outline a method for studying how the five factors of change mentioned above *themselves* change. With care, this engine can be run in reverse – not just to study change, but to bring it about.

1. **Develop empirical studies and a critical apparatus** : $\nabla$ *context*
2. **Find companions for the journey** : $\nabla$ *metalearning*
3. **Work with real users** : $\nabla$ *feedback*
4. **Study and build nonlinear interfaces** : $\nabla$ *distributivity*
5. **Limit philosophizing** : $\nabla$ *achievement*

Chapter 5 describes the connections between these five dimensions and the design pattern methodology that is applied in Chapter 9. Together, the two levels of change are similar to what Gregory Bateson calls *proto-learning* and *deutero-learning*, or, more plainly, Learning I and II (Bateson, 1972, pp. 174, 292–306). Bateson's perspective on learning is discussed in Chapter 4, where it is used to illustrate the connections and differences between paragogy and other contemporary learning theories.

## 3.4 Summary

This chapter presents paragogy, a new theory of peer produced peer learning. Paragogy is different from earlier theories of learning, in the sense that broader contextual change is considered along with change in the persons who are learning.

Although paragogy initially developed in the mode of constructive critique, it is not tied to a project of "*fixing*" education; *cf.* (Kernohan, 2013). Indeed, paragogy is not presented primarily as an educational approach, but as a description of the way learning works in peer production communities. Paragogy has been amplified and extended within the Peeragogy project (Rheingold et al., 2014), which has helped make it useful to educators (Purser, Towndrow, & Aranguiz, 2013; Baker & Surry, 2013), and others (Corneli et al., 2014).

In order to give a foundation to the key ideas in paragogy, the presentation in this chapter has drawn on course design, participant observation, and on subsequent papers that explored the relevance of paragogy for system design and research (Corneli & Mikroyannidis, 2011; Corneli, 2012).

# 4 Literature Review

**While there is no significant prior literature on "peer produced peer learning," the paragogy framework suggests a way to organize and survey prior work in adjacent fields.**

## 4.1 Prelude: Learning and adaptation

This section will explore *learning*, focusing on Gregory Bateson's (1972) perspective, which was introduced briefly in the previous chapter [§3.3, p. 41], connecting it to the notion of *adaptation* that appears frequently in anthropological literature. The recent work of Andreas Meiszner (2010), who studied learning in the setting of free software and open courses, helps to show how these ideas relate to practical application and to contemporary learning theories. In the later sections of this chapter, this material will be useful in analyzing the literature related to peer produced peer learning in mathematics.

Bateson's hierarchy *Learning I*, *Learning II*, *Learning III*, etc., begins with *Zero Learning*, which denotes no change in the subject, only a stimulus and a reaction that is already "*soldered in*" (Bateson, 1972, p. 288). As with paragogy, Bateson understands learning to be fundamentally related to change, but in his model, he imposes the requirement that the environment should *not* change while learning is happening. His assertion is that "[t]*he notion of repeatable context is a necessary premise for any theory which defines 'learning' as change*" (Bateson, 1972, p. 296). Bateson does allow a hedge, which is that the context is only "*somehow*" or "*theoretically*" the same. The problem is that, here, Bateson is understanding context as "*a metamessage which classifies the elementary signal.*" Rather than talking about a repeatable context, it would be clearer to simply say that the stable classification of signals is what is important. Even in the case where a

bell sometimes means dinner and sometimes means no dinner, there is something to be learned, which is that the bell is capricious. All classification systems must "*fit innumerable, more or less similar cases – which means, strictly speaking, never equal*" (Nietzsche, 1873). Indeed, in some sense, what one is learning is precisely the classification system, with whatever built-in uncertainty pertains to it. This is compatible with Bateson's more formal definition: "*Learning I is change in the specificity of response by correction of errors of choice within a set of alternatives*" (Bateson, 1972, p. 298). The definition of Learning II, naturally enough, builds on the definition of Learning I:

> *Learning II is a change in the process of Learning I, e.g. a corrective change in the set of alternatives from which choice is made, or* [...] *a change in how the sequence of experience is punctuated.* (Bateson, 1972, p. 298)

Getting better at solving problems of a given type over time is an associated phenomenon, which related to the notion of *transfer of learning* whereby a problem in a new context is treated as if it were the same as a problem encountered in an earlier training context. Again, context change is perfectly compatible with learning at this level.

As an important class of examples, day-to-day communication works largely due to the fact that "*the stream of events is commonly punctuated into contexts of learning by a tacit agreement between the persons regarding the nature of their relationship*" (Bateson, 1972, p. 304). The pattern by which we should define Learning III and so forth is now relatively clear. Since "*what is learned in Learning II is a way of punctuating events*" (Bateson, 1972, p. 305) then what is learned in Learning III is a way of punctuating the punctuation of events – and so on. In other words, Learning II is about creating the boundary conditions in which a given pattern of control will be exercised, subject to the standard caveat that this control is partial. In a paragogical view, punctuation of this sort could also be called *context creation* – although often more is involved in context creation than just bracketing.

Bateson introduces several additional ideas that expand on this hierarchy, and which will be useful in what follows. The first is the distinction between analog and digital signals. Often the two are combined, as in language learning (Iverson & Thelen, 1999); indeed, "*there is a continuous gradation from the ostensive through the iconic to the purely digital*" (Bateson, 1972, p. 296).

For example:

> [A]*n English-speaking mathematician confronted with a paper by a Japanese colleague* [...] *gazes uncomprehendingly at the Japanese ideographs, but he is able to partly understand the Cartesian graphs in the Japanese publication.* (Bateson, 1972, p. 378)

Digital signals generally have conventional interpretations (*e.g.* the bell), whereas analog signals are more direct (*e.g.* the dinner), and need not stand for anything else. Clearly any conventions must be learned in order to be used. "*Verbal language*," in particular, is "*almost (but not quite) purely digital*" – and furthermore, "*primarily oriented toward things*," rather than "*the patterns and contingencies of relationship*" (Bateson, 1972, pp. 378, 377).*

Here, *relationship* especially means a context for communication, which as we've seen, means a context for learning, and, more broadly, a context in which cybernetic control is exercised. Bateson shows through many examples that humans and other mammals typically communicate about their most meaningful relationships with one another in nonverbal – *i.e.*, analog – ways. He introduces the term *μ functions* to describe communication acts, whether digital or analog, spoken or unspoken, which are ways of "voicing" relationship.

> *We shall say that "A dominates B" if A and B show by their behavior that they see their relationship as characterized by sequences of the type $a_1 b_1 a_2$ where $a_1$ is seen (by A and B) as a signal defining conditions of instrumental reward or punishment; $b_1$ as a signal or act obeying these conditions; and $a_2$ as a signal reinforcing $b_1$. Similarly we shall say that "A is dependant on B" if their relationship is characterized by sequences $a_1 b_1 a_2$, where $a_1$ is seen as a signal of weakness; $b_1$ as a helping act; and $a_2$ as an acknowledgement of $b_1$.* (Bateson, 1972, p. 305)

Some examples may help clarify these concepts. Wittgenstein's builders operate at the level of Learning I and execute a digital program – "*so that A can shout 'red slab!', and B will pass slabs of a certain colour*" (Bloor, 1983, p. 22). Given the thin description, we don't know for sure that *A* dominates *B*, which is certainly what it sounds like, or is perhaps dependent on *B*. In any case, the language of the builders is entirely about things, and the relationship is "voiced" through the embodied pattern of compliant acts.

In a real-world example, Richard Stallman solved a problem with printer jams at the MIT AI lab by installing custom code "*to notify every user with a waiting print job that the printer was jammed.*"

> *"If you got that message, you couldn't assume somebody else would fix it," says Stallman, recalling the logic. "You had to go to the printer. A minute or two after the printer got in trouble, the two or three people who got messages arrive to fix the machine. Of those two or three people, one of them, at least, would usually know how to fix the problem."* (Williams & Stallman, 2010, p. 3)

*Note that Geertz does not precisely say that a *symbol* is digital, but his list of exemplars – "*any object, act, event, quality, or relation which serves as a vehicle for conception*" – is comprised of discrete terms, rather than processes; in particular, a *relation* rather than a *relationship*. *Cf.* [§1.4, p. 9].

This message had the $\mu$ function of expressing a relationship between particular individuals and a printer, but it also served as a collective expression of the mutual interdependence of the members of the lab as a whole. This episode was an example of Learning II, enacted in such a way as to change the punctuation of experiences for the group. Furthermore, it served as a motivating example for an episode of Learning III, leading to the creation of the GNU project – based on the observation that custom messaging was only possible because the source code that controlled the printer's was accessible and could be changed.

It is now possible to make connections from this theoretical view to some of the standard learning theories. Here, I will largely follow in the footsteps of Andreas Meiszner (2010), whose PhD thesis asks whether the kind of learning that happens in free software communities can be applied to build open courses. Chapter 2 was framed around a similar motivation: "Can we make learning mathematics more like learning in free software?"

Meiszner draws on the description of self-directed learning from Gerald Fischer and Eric Scharff (1998), who write about the potential of "*Economies of Educational Knowledge*" that can be used by self-directed learners. According to Fischer and Scharff:

1. **Learning requires environments in which learners can be active designers and contributors.**
2. **Learning is highly tuned to the situation in which it takes place.**
3. **Learning is knowledge-dependent.**
4. **Learning needs to account for distributed cognition.**
5. **Learning is affected as much by motivational issues as by cognitive issues.**

These points bear a manifest similarity to the paragogy principles [§3.1, p. 36], however Fischer and Scharff retain a basically provisionist orientation. Their primary interest is in "*support for*" self-directed learners who act "*primarily as designers of some artifacts*." This is, indeed, the typical case in peer production, and the basic form in *constructionism* (Papert & Harel, 1991). However, as there is little emphasis on co-creating the learning context, this is a kind of "proto-paragogy."*

By and large, Meiszner finds the above-listed characteristics "*well presented within FLOSS*." He documents further specific features of the way learning works in free software communities, for instance, he notes the "*fragmentation and self-selection of learning materials*." He extracts sensible-sounding recommendations for designers of open courses, for example: "*Enable learners to engage* [with] *activities that are not restricted to*

*Fischer and Scharff's primary sources are Lauren Resnick (1989) for the first three points, who grounds them in the cognitive science literature; the contemporary work of Mitchell Resnick (1996) on distributed constructionism for the fourth point; and Mihály Csíkszentmihályi (1990) for the fifth.

*an artificial university setting*" and "*Implement peer support mechanisms - a large support network provided voluntarily by peers in a collaborative manner nearly 24/7.*" The problem then becomes, who will implement these proposals?

*Connectivism*, introduced by George Siemens, emphasizes the role that "*self-organizing networks*" and "*actionable knowledge*" play for learning in the "*Digital Age*" (Siemens, 2005). Massive Open Online Courses (MOOCs) designed with a connectivist orientation have many features matching Meiszner's recommendations. However, there seem to be some important differences.

> [O]*ne of the cornerstones of learning in FLOSS, is to 'enable re-experience', to 'learn from what others did',* [...] *Most of the discourse, debates or discussions of the CCK08 course are very close to the FLOSS case, a significant difference however is that those activities do not culminate within a 'solution', 'product', 'guide', 'report' or other type of 'concrete outcome' that would allow future cohorts to take this outcome as a starting point.* (Meiszner, 2010)

As the *Connectivism and Connective Knowledge* course was re-run a few years later as CCK11, this assertion must be questioned.* Nevertheless, the emphasis for most participants in connectivist MOOCs has been on "*dialogical*" features (Ravenscroft, 2011) – crafting an experience rather than a product. Without a doubt, such conversations are peer produced – but, still, without any aspersions, this is the kind of learning that takes place on "*Facebook, Twitter, G+, blogs, and other media*" (Purser et al., 2013), rather than the kind of learning that takes place in free software projects. In framing the central tenets of connectivism, George Siemens remarks that "*The pipe is more important than the content within the pipe*" (Siemens, 2005). The broad success of technologies for communication like StackExchange in learning applications notwithstanding, the paragogue would rather side with René Magritte here – "*Ceci n'est pas une pipe.*" Rather, after Benkler,

> *There is simply the question of governance in the relations among users of a class of software platforms that have certain degrees of freedom in their design, resulting in a variety of social affordances, and therefore facilitating a variety of social and economic interactions.* (Benkler, 2006b)

In this respect, paragogy is closer to *constructivism*, inasmuch as the latter, at least in its "radical" form, places an emphasis on *adaptation* rather than on knowledge transfer. As per Ernst von Glasersfeld, "[t]*o be adapted* [...] *means no more and no less than to be viable*" (von Glasersfeld, 1996). However, while von Glasersfeld intends for radical constructivism to be compatible with "*an ontological 'reality'*," he asserts that his framework "*denies the human experiencer the possibility of acquiring a true representation of*

*http://cck11.mooc.ca/

*it*" (von Glasersfeld, 1996). Bateson, for his part, would reject the separation of mind from body that this entails (Bateson, 1972, p. 470). Von Glasersfeld's focus on the construction of conceptual schemes and models leaves out broader contextual and relational features that are present, for example, in Vayda and McCay's perspectives on environmental change and group-level action and selection, which consider the adaptivity of the entire "*process of response*" [§3.1, p. 37].

Paragogy not only "*eschews pipeline models of transmitting knowledge*" (Papert & Harel, 1991) but treats communication as an assemblage with emergent properties, co-constituted by its participants, and subject to the vagaries of existence in the real world. In this, respect, we find paragogy at once in both its (em)*phatic* and *productive* senses.* Following Malinowski (1936), Julia Elyachar explains her concept of *phatic labor*:

> *Malinowski shows how language such as gossip and chatting can be a means of establishing ties for their own sake, rather than for the purpose of conveying any information in particular.* [...] *I argue that this labor produces communicative channels that can potentially transmit not only language but also all kinds of semiotic meaning and economic value.* (Elyachar, 2010)

The synthesis of a channel relies on the key feature that makes context creation different from the mere punctuation of experience, and different from standard models of communication: "*There is always more in the effect than there was in the cause*" (Harman, 2008). But these emergent effects must be *channeled*, or else they dissipate (Deacon, 2014). In short: paragogy is concerned with generating and voicing the $\mu$ functions that sustain relationships in which learning can take place, and through which meaning can be made. This process is "*morphogenetic*," not "*hylomorphic*" (Ingold, 2013, pp. 21–22) – but moreover it is associated with problems which possess an objective reality, as when "*a population of interacting physical entities, such as the molecules in a thin layer of soap* [...] *adopt a form which minimizes free energy*" (DeLanda, 1998). In the case of PlanetMath, with reference to the framework from Chapter 3,

1. **The co-created context is a mathematics website,**
2. **in which learning is part of a social knowledge building process,**
3. **carried by mediated peer feedback,**
4. **which unfolds in an architecture devised to support collaboration;**
5. **wherein the "dream" is one of shared community.**

Bringing together and contextualizing accounts from key figures associated with these themes, the chapter arrives at a picture of mathematical sociality that can be used to reframe the research question as an array of related research problems (Chapter 5).

* *Cf.* [§1.6, p. 14, Footnote ∗].

## 4.2 Mathematical thinking

How do people understand mathematics? This is the key issue in William P. Thurston's paper, "On Proof and Progress in Mathematics". Thurston had this admonishment for the mathematics community:

> *We need to focus far more energy on understanding and explaining the basic mental infrastructure of mathematics – with consequently less energy on the most recent results.* (Thurston, 1994)

| |
|---|
| human language |
| sensory perception |
| logic and deduction |
| intuition, association, and metaphor |
| stimulus/response |
| process and time |
| socialization |

**Table 3:** *Criteria from William Thurston*

Note the emphasis here is on the *human experience* of mathematics. Thurston particularly emphasizes the importance of a social dimension for building a successful mathematics research programme. He begins with a point drawn from his own experience and very similar to Eric Raymond's insight that "*some very successful projects become 'category killers'*" (Raymond, 1998). Rather than clearing out mathematical topics on one's own, he observes that the long run it is much better to involve other people.

Thurston points out that people are able to make use of a wide, embodied channel to get involved. The way people *think* about mathematics (Table 3) is vastly different from what we see in the relatively dry and disembodied channel that typifies mathematics *papers*. Thurston describes mathematics as "*the theory of formal patterns*."* Nevertheless, he argues that

> [R]*eliability does not primarily come from mathematicians formally checking formal arguments; it comes from mathematicians thinking carefully and critically about mathematical ideas.* (Thurston, 1994)

**The heart of mathematics** *Problem solving* is considered by Paul Halmos to be "*the heart of mathematics*" (Halmos, 1980). Together with Thurston's definition, this speaks to a dual role for problem solving activities: they cross back and forth between the informal, experiential, "human" ways of thinking about a problem, and more "formal" static results (solution, proof, often "correct", etc.). "[T]*he mathematician's main reason for existence is to solve problems*" (Halmos, 1980). Adding problem solving interactions is a key "ergonomic" step in PlanetMath/Planetary, since it brings it into closer alignment

*He remarks, "*to discuss this would be a whole essay in itself.*" Thurston may be thinking here of formal structural organizations, not only in terms of logic; *cf.* (Thompson, 1917), (Alexander, 1964, p. 134). Thurston's former student Benson Farb indicates: "He changed our idea of what it means to 'encounter' and 'interact with' a geometric object. The geometry that came before almost looks like pure symbol pushing in comparison." HTTP://BLOGS.SCIENTIFICAMERICAN.COM/OBSERVATIONS/2012/08/23/THE-MATHEMATICAL-LEGACY-OF-WILLIAM-THURSTON-1946-2012/

with what people *do* when they do mathematics. Michael Atiyah argues that the "*core*" of mathematics is has as least much to do with theory building as it has to do with problem solving:

> [W]*hat is the good of a theory if it does not solve problems and what is the good of an infinite collection of disjoint problems, however interesting each individual one may be.* (Atiyah, 1974)

Timothy Gowers emphasizes that both problem solving and theory building can achieve the important end of organizing and communicating mathematical thought (Gowers, 2000). It would seem that communication lies near the heart of mathematics – and if that is so, then surely the choice of media for mathematical communication matters.

**Studying mathematics online** Khan Academy was discussed briefly in Chapter 2. If we look beyond the video format and the associated flipped-classroom pedagogy (Bergmann & Sams, 2012; Khan, 2012) we can say a bit more. Remarking on an inherently collaborative online mathematics learning environment, the Virtual Math Teams project, Gerry Stahl suggests that people studying online collaboration are in an uniquely good position, since they have access to the same information that participants in these environments have (Stahl, 2010). This is not even the case for persons researching *offline* interaction, who typically need to apply instruments like think-aloud protocols to build an explicit trace of what people are thinking (Nielsen, Clemmensen, & Yssing, 2002). (Of course, in practice, the users of an online system may have scratch work or side-conversations that are in no way indexed by the system.) One exemplary piece of recent research in this genre is a project on collaborative online peer supported proof-generation exercise that was conducted by Alison Pease and Ursula Martin. "Seventy four minutes of mathematics" (Pease & Martin, 2012) analyzes the activities that took place during *Mini-Polymath III*, a project in which Terrence Tao invited students to collaborate on his blog to solve an old Mathematical Olympiad problem. Having access to a trace of the entire conversation allowed Pease and Martin to categorize contributed comments as *concepts*, *examples*, *conjectures*, or *proof-related* – a framework inspired by Imre Lakatos's (1976) theory of informal mathematics.

**Questions of procedure** The Polymath project, which served as the inspiration for the Mini-Polymath series, aimed to answer the question "*is massively collaborative mathematics possible?*"* This project was convened by Timothy Gowers, who developed 15 rules to address the "*questions of procedure*" that he anticipated would arise.†

*http://gowers.wordpress.com/2009/01/27/is-massively-collaborative-mathematics-possible/

†http://gowers.wordpress.com/2009/02/01/questions-of-procedure/

In particular, the rules emphasize that a good contribution represents a "*quantum of progress*." Gowers progressively and carefully explicated the imperative to share comments that are "*not fully thought out.*" As Ursula Martin had commented ten years earlier with regard to the emerging field of *experimental mathematics*, that the growth of experimentation requires the "*development of community standards as to experimental methodology*," emphasizing not only technical matters, but also "*the early sharing of insights*" (Martin, 1999). Community standards are essentially synonymous to community norms, like those we would have liked to see more clearly elucidated at P2PU (Chapter 3 [§3.2, p. 39]). Community standards are part of any technology for shared communication; without them, communication is more difficult, or impossible; *cf.* Bateson on the tacit agreements that create contexts for learning [§4.1, p. 44].

Gowers's rules provide one starting point for community standards in *social* experiments in mathematics. These rules suggest a fairly precise understanding of mathematical socialization. It is not simply a matter of chatting things over, rather, it is a slow process of big ideas, and a faster intermediate process of breaking these ideas down into smaller parts. This recovers the *modularity* and *granularity* aspects the Commons-Based Peer Production model. Ultimately, participation in the Polymath project was not as "massive" as had been hoped (Gowers & Nielsen, 2009). This points to a potential expanded role for *integration*: not only to connect ideas into finished products, but also to connect the workflows of more persons. At the same time, the question about massive collaboration in research needs to be made more precise. Reasonably large scale collaboration in research mathematics had been going on much earlier, after a fashion: consider Mersenne's 17th century system (Bartle, 1995); and for a review focusing on Bourbaki, see Leo Corry on "Writing the Ultimate Mathematical Textbook" (Corry, 2009).

**Making mathematical meanings** There is a correlate to the quantum of progress in research mathematics to be found in a paper by Constant Leung about the process of learning elementary mathematics (Leung, 2005). Leung mentions three key points about learning mathematical language, and *mathematical vocabulary* in particular. Leung points out that when you learn mathematics, you have to learn both "*formal*" and "*semantic*" features of the concepts involved*; you have to "*think through*" the concepts involved; and that learning it is "*incremental*," in that meanings expand and develop by building on one another. This tells us what mathematical vocabulary does. Introducing new terminology is a way to represent new ideas – a quantum of progress in a learning or discovery process. It would not be entirely unreasonable to take learning vocabulary as a model for learning mathematics.

*Thus, for instance, a square is "*a figure with 4 straight equal sides forming 4 right angles*" (*formal/core*), and "*it has four lines of symmetry, and rotational symmetry of order 4*" (*semantic/non-core*).

> [W]*ords don't just represent what we claim to know already, they also allow us to make observations and to formulate novel meanings within a negotiated range of acceptable/accepted possibilities or limits.*" (Leung, 2005)

**Mathematical semiotics** Michael Halliday's view that a language contains terminology *and* a theory of human experience *and* an enactment of interpersonal relationships (Halliday, 2006, p. 50) is consistent with Leung's view that learning words is actually a matter of learning and enacting process, and consonant with Thurston's perspectives on mathematical experience. Halliday makes it clear that learning scientific or mathematical language is not just a matter of learning new vocabulary words. Writing about students learning science, Halliday said that the difficulty is not just with "*technical terms*" but with the "*the total patterns of the discourse*" (Halliday, 2006, pp. 200–201). The salience of these comments is amplified when we consider Halliday's language-based theory of learning, which says that, for humans, learning how to relate to others, and indeed learning how to think, are intrinsically linguistic processes. To illustrate these claims, Halliday presents a detailed study of the development of thought through 21 distinct features of childhood language development (Halliday, 1993). In this work, all human learning activities are seen as "*semiotic*": the system of language is concomitant with processes of meaningful acts. Halliday's thinking about system and process is reminiscent of Louis Hjemslev's thesis:

> [F]*or every* ***process*** *there is a corresponding* ***system****, by which the process can be analyzed and described.* (Hjelmslev, 1961, p. 9), original emphasis

In this way, we move back and forth between words/symbols, system/language, and process/meaning.

**Learning mathematics from examples (and by doing)** But does a language-based theory adequately describe the way people learn mathematics? A paper by Xinming Zhu and Herbert A. Simon demonstrates the feasibility of an alternative learning-by-example approach (Zhu & Simon, 1987). In this case, the examples were spelled out in advance in textual form. The underlying model is simple, and best suited for rote learning (Waterman, 1975). This approach to learning from worked-out examples contrasts strong with the "*Moore method*" (Jones, 1977; Cohen, 1982), a variation on the practice known as "*discovery learning*" (Bruner, 1961). Here, the syllabus consists of a selected list of theorems to prove. Clearly, in order to prove non-trivial theorems, one needs "*a reasonable degree of sophistication concerning the logic of verification and concept formation*" (Strike, 1975). The Moore method generally relies on the rediscovery of a known system behind the revealed process. On the other hand, the Zhu/Simon model is an example of a system with only a minimal process: it provides a limited language that only

| | |
|---|---|
| | If a problem seems familiar, try *reasoning by analogy.* If you solved a similar one in the past, and can adapt to the differences, you may be able to re-use that solution. |
| | If the problem still seems too hard, *divide it into several parts.* Every difference you recognize may suggest a separate subproblem to solve. |
| | If it seems unfamiliar, *change how you're describing it.* Find a different description that highlights more relevant information. |
| ▽ | If you get too many ideas, then *focus on a more specific example* – but if you don't get enough ideas, make the description more general. |
| | If a problem is too complex, *make a simpler version* of it. Solving a simpler instance may suggest how to solve the original problem. |
| | Asking "*what makes a problem hard?*", may suggest another approach – or a better way to spend your time. |
| | When your ideas seem inadequate, remember someone more expert at this, and *imagine what the expert would do.* |
| ⊗ | Whenever you find yourself totally stuck, *stop what you're doing* now and let the rest of your mind find alternatives. |
| | The best way to solve a problem is to already *know how to solve it* – if you can manage to retrieve that knowledge. |
| | If none of these methods work, you can always *ask another person for help.* |

**Table 4:** *Problem-solving heuristics suggested by Minsky, with new mnemonics*

makes it possible to reexpress the guiding text. When compared with Halliday's detailed developmental model of learning as a linguistic/semiotic/meaning making process, both of these models appear quite flawed.

**A linguistic desert** In a series of memos written for the One Laptop per Child (OLPC) project,* Marvin Minsky points out that young students are not given many mathematical words or ideas. "*It is hard to think about something until one learns enough terms to express the important ideas in that area*" (Minsky, 2008–2009).† However, Minsky's concern is not solely with increasing the rate of vocabulary acquisition, but with learning new ways to think and problem solve. He proposes several example heuristics (*i.e.*, ways of thinking about problems) that could be taught to students (Table 4). In the OLPC memos, he suggests that programming may be a better way to teach heuristic reasoning than mathematics. Elsewhere, Minsky emphasizes that to build real understanding, it is necessary to be able to "*represent something in several ways*" (Minsky, 2007, p. 6).

*HTTP://ONE.LAPTOP.ORG/

†*Cf.* Gerry Sussman: it's "*hard to learn what one cannot express*" [§3, p. 10].

## 4.3 Collaborative knowledge building

The model of learning from discovery and examples, where both are embedded in a social process, is similar to Marlene Scardamalia's (2002) conception of knowledge building, mentioned in Chapter 3. These ideas build upon earlier work that was developed jointly with Carl Bereiter (Bereiter, 1994; Bereiter & Scardamalia, 1993; Bereiter, Scardamalia, Cassells, & Hewitt, 1997). These works emphasize heuristic design guidelines such as: "*There is a way into the central knowledge space for all participants*" (Scardamalia, 2002).

| Tacit preunderstanding |
|---|
| Personal attention (⋆) |
| Personal comprehension (⋆⋆) |

| (⋆) Personal attention |
|---|
| Public statements |
| Argumentation and rationale |
| Shared understanding |
| Collaborative knowledge |
| Cultural artifacts |
| (⋆⋆) Personal comprehension |

**Table 5:** *Criteria from Gerry Stahl*

"A model of collaborative knowledge building" is a short paper by Gerry Stahl (2000), in which he talks about "*learning as a social process of knowledge building*." The aim of Stahl's paper is to add a cognitive dimension to the early, more informal, theories of knowledge building. In particular, the paper aims to mesh "*personal understanding*" (considered as a cycle) with "*social knowledge building*" (considered as another cycle) – see Figure 4.* Table 5 presents a minimal rendition of the diagram's main generative cycles and mutually-satisfying boundary conditions.

Stahl's model does an admirable job of organizing the key ideas of social knowledge building, while simultaneously offering a potentially descriptive theory. However, as a cognitive model, it remains fairly schematic.

**Another candidate structuration** In a recent paper by Sean Goggins and co-authors, Stahl's work on collaborative knowledge building inspires another graphical interpretation (Figure 5), where *context*, *people*, *artifacts*, and *interactions* are organized in *contextualized interaction* (Goggins, Mascaro, & Valetto, 2013). This model also considers people, artifacts, and a shared context. There is less of a focus on the particular *teloi* of belief, understanding, and comprehension. However, there is more of an emphasis on small-scale feedback loops, which are connected to a large-scale research cycle that aims to identify the social connections that are created within the groups being studied.

**Modeling the process of learning** "Modeling the process, not the product of learning" (Akhras & Self, 1999, pp. 3–28) was published around the same time as Stahl's short paper. Here, Fabio Akhras and John Self look for ways to model learning within a

*In this revision to Stahl's (2000) diagram, "*social knowledge building*" splits into "*small group interaction*" and "*commmunity knowledge building*", and what was formerly "*personal belief*" is now labeled "*personal attention*" (Stahl, 2013).

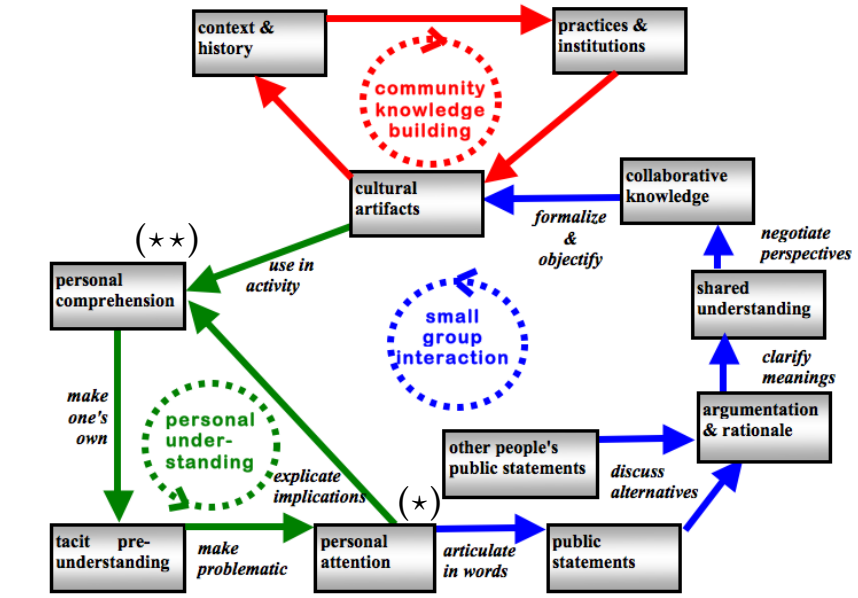

**Figure 4:** *Stahl's diagram of factors involved in collaborative knowledge building, Figure 8-4 from* Translating Euclid: Creating a human-centered mathematics, *© 2013 Gerry Stahl (used with permission; annotations* $(\star)$ *and* $(\star\star)$ *added to indicate the points of departure and arrival for the two main cycles)*

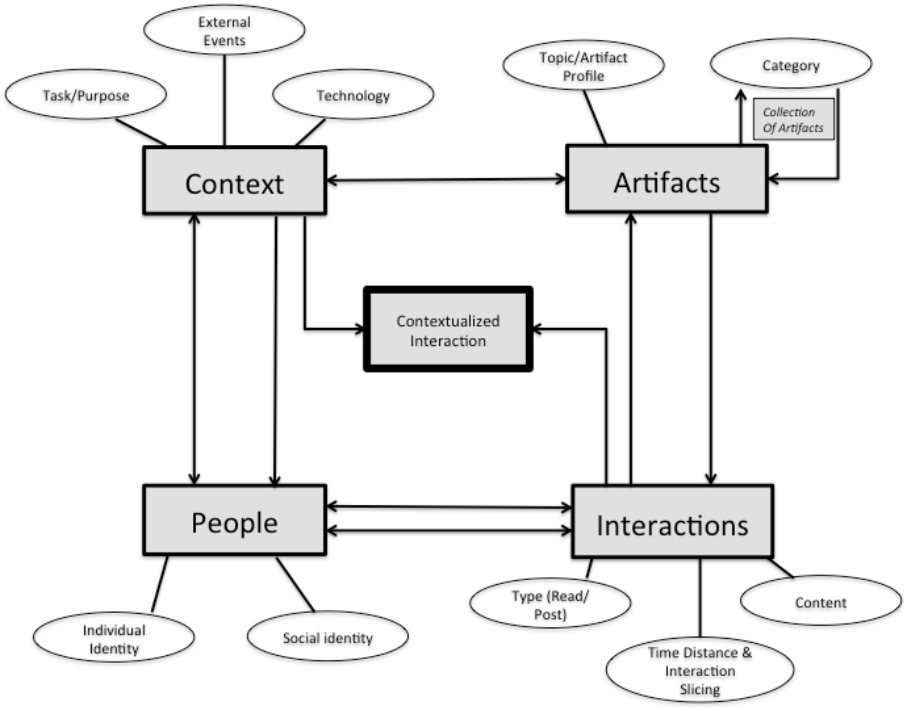

**Figure 5:** *Overview of the Group Informatics Model, Figure 1 from "Group informatics: A methodological approach and ontology for sociotechnical group research", © 2013 Sean Goggins (used with permission)*

"*constructivist mindset*." The classic approach to student modeling in intelligent tutoring systems seeks to capture domain knowledge in certain objective representations, which the student is then supposed to internalize – they cite Wenger (1987) as an example. According to Akhras and Self, knowledge is an inherently process-based phenomenon that "*cannot be objectively defined and statically represented.*" Akhras and Self therefor restrict themselves to modeling the "*context*," "*activity*," and "*temporal factors*" of learning. In a subsequent work, they go on to argue that "*if you want to take a constructivist approach the ITS framework will not help because of the different issues addressed*" (Akhras & Self, 2002). Commentators Michael Young et al. (2002) use Akhras and Self as a launch point to call for the consideration of the multidimensional nonlinear dynamics associated with learning interactions – a perspective that is quite sympathetic to the paragogical view.

**The (multidimensional) Zone of Proximal Development** As certain basic problems get easier to solve, people move on to more difficult ones. This principle is perhaps best studied within the field of child psychology, where it was formalized by Lev Vygotsky as the *Zone of Proximal Development*,

> *a sphere formed by the aggregate of vectors that pass through a 'point' of difficulty and that delineate a child's diverse possible areas of development.* (Zaretskii, 2009)

When the learner moves within this multi-dimensional "*zone*," he or she may overcome particular difficulties with the help of competent others. Once a given challenge can be satisfactorily met with help, it can often later be managed independently. Of course, we do not assume that social interactions, *per se*, will always have a positive effect on development or learning (Hogan & Tudge, 1999, p. 61). In particular, we cannot expect that a given peer will have the skills or sensitivities needed to help navigate and maintain the ZPD of another (*ibid.*, p. 57). The multidimensional Zone of Proximal Development provides a satisfying generalization of the basic form described by Stahl (see Figure 4 and Table 5, above). Both systems are reminiscent of the *microsphere* defined by Peter Sloterdijk, whose key feature is its bi-centered nature and whose basic paradigm is life in the womb (Sloterdijk, 2011, p. 540).

**The emergence of mathematical meaning** Cobb and Bauersfeld (1995) present an edited volume containing several detailed analyses of classroom-based teaching and learning practices. The focus is on examining what happens when the teacher shifts from a pedagogy revolving around teaching what is seen as the correct way to think about things, to pedagogy where the teacher is, or tries to be, genuinely interested in the way students think as well. For example, students are encouraged to come up with their own ways to add numbers like 56 and 67. In addition to the traditional strategy of lining up the numbers in columns and carrying digits, one might round down to 55 plus

65, see that this is the same as $60 \times 2$ and add back the 3 points from rounding at the end. Or one might work the sum as $(50 + 6) + (60 + 7)$. If not limitless, the varieties of mathematical experience are at least highly diverse, and it seems the teacher must quickly muster some patience to deal with the enthusiastic creativity of her pupils, while also remembering to encourage them to reflect on one another's ideas. This appears to be an effective way to teach mathematical creativity. However, one wonders how much interest the student answers really have for the teacher, especially after the curriculum has been run several times. Ilana Horn underscores that "[t]*he focus on student thinking requires a genuine curiosity about young people and their ideas*" (Horn, 2012). Relating recent pedagogical experiments in the JUMP Math project, John Mighton writes:

> *Research has shown that many elementary teachers* [...] *are mathphobic or have very rudimentary knowledge of math.* [...] *In following the online lesson plans* [from JUMP Math] *teachers learn the math as they teach. Many have become excited about their new understanding of the subject and have formed volunteer networks to support and mentor other teachers.* (Mighton, 2014)

These examples illustrate a view of mathematics education in which peer pedagogy and paragogy are potentially compatible, featuring ongoing, active, and creative learning for all involved. The emergence of mathematical meaning goes along with the formation of new practices, for example, effective practices of metacognition, as described by Alan Schoenfeld [§1.3, p. 9] – and may be accompanied by new social arrangements, as described by Mighton. Indeed, the social in Mead's sense of an unstable "*betwixt and between*" [§1.3, p. 8] tends to be well exemplified in learning; *cf.* (Deleuze, 1968, p. 204).

The following section emphasizes the role emergence can play in the co-creation of an environment that meets the proximally-developmental needs of the peer learner, whose not-just-(en)cyclical learning style has been traced above.

## 4.4 The ecological approach in learning design

"The Ecological Approach to the Design of E-Learning Environment: Purpose-based Capture and Use of Information About Learners" is a paper by Gordon McCalla that talks about how to use interaction data to help build a learning environment (McCalla, 2004). McCalla does not use the word "stigmergy" in this paper, but his view of mediated interaction matches that definition well, if we understand *stigmergy* to mean:

> [T]*he use of environmental conditions as instigators of action and the overall ability of the group to perform problem-solving activity that exceeds the knowledge and the computational scope of each individual member.* (Clark, 1998, p. 234)

A key part of McCalla's view is that the system adapts as its external environment

changes, where its "*external environment includes learners, teachers, the subject matter being learned, and the technology that implements the e-learning system.*" Such a perspective is in line with the broader *emergentist* approach in cognitive science (and robotics), in which systems are programmed directly by the environment, and can make use of environmental features for purposes of self-programming (Clark, 1998).

The idea in McCalla's model is to engineer systems that can capture information about users and individual use events. Data describing use events has elsewhere been given the convenient name "*paradata*," to distinguish it from "*relatively static metadata*" (National Science Digital Library, 2012).*

| |
|---|
| Gradual, localized, accumulation of information |
| Focus on information about the end user |
| Purpose-based use of data, in support of a pragmatic web |

**Table 6:** *Criteria from Gordon McCalla*

These ideas coalesce into a scheme (Table 6) for capturing use data related to learning, by "*attaching*" a model of the learner to each object the learner uses. This model is considered to have "*characteristic*" and "*episodic*" aspects (*metadata* about the user, and *paradata* about the specific use event). The data is to be used by "*purpose-based*" data clustering and data mining algorithms.

**Good contributions and good questions** Q&A sites make reasonably transparent use of paradata (upvotes, downvotes, and accepted answers, as well as editing behavior) to award points and badges of markers of progress. They provide a concrete example of *marker-based stigmergy* in action, and a partial implementation of McCalla's vision. Since pragmatics is at issue, it's worth asking: what makes a good contribution on a Q&A site? The first basic finding is that good online contributions tend to mirror good offline contributions. Tausczik and Pennebaker (2011) showed that strong mathematicians (according to offline metrics) are more likely than other participants to ask highly rated questions on the mathematics research Q&A site MathOverflow. Anderson, Huttenlocher et al. (2012) examined MathOverflow's big sister, Stack Overflow, and found that questions that appear together with multiple different answers brings lasting value to the site. Another striking finding was that the events that take place within the first hour after a question is posted are reliable predictors of its subsequent interest up to a year later.

Reflecting on her experiences with students in an offline setting, Alison King (1999) captures the essential message: "*thought-provoking questions promote high-level discussion, which has been found to result in high-level learning.*" King divides questions into two categories, *comprehension questions* – which seem well-suited to dealing with factual

*The term "paradata" was previously used in an approximately similar manner in the context of survey-based research, see Safir et al. (2001).

material – and *connection* or *integration questions*, which are more suited to analyzing and integrating ideas. Combining these with *strategic* questions, peer learners can tackle ill-structured problems.

**Still more mathematical meaning** One can look for meaning throughout a wide range of actions and interactions, for example, solving a problem, asking a question, and giving or receiving a hint. These activities may have further subjective features, including "*processing level*," "*quality of self-explanation*," and "*interest in exploration*" (Hosein, 2009). Relational or contextual features of behavior are likely to be particularly significant. Chan, Lee, and van Aalst (2001), drawing on Scardamalia (2000), described "*Working at the cutting edge*," "*Collaborative effort*," and "*Identifying high points in the discourse*." There are many ways in which this sort of distributed collaboration can be recognized and persisted to add value to a resource; *cf.* Corneli and Mikroyannidis (2011).

**Sticking things together** "*Local solutions to local problems*" is the watchword for Elinor Ostrom's theory of commons governance (Ostrom, Burger, Field, Norgaard, & Policansky, 1999). Local features are also important in McCalla's proposal to implement educational systems using *localized* accumulation of information. Martin Nowak's work is tremendously useful because it points to a kind of glue – "*cooperation*" — that can be used to stick local regimes together (Nowak, 2006). Nowak's five rules for the evolution of cooperation are quite simple:

1. **Cooperate with agents to whom you are sufficiently related.**
2. **Cooperate with agents who help you.**
3. **Cooperate when it improves your reputation.**
4. **Cooperate with agents in your locale.**
5. **Cooperate with agents in a designated "group" that you belong to.**

**A pragmatic web** King's (1999) discourse patterns for collaborative inquiry provide a simple implementation of "*the gradual, localized, accumulation of information* [...] *in support of a 'pragmatic web'*." Following Geertz we might accept a more typical name for this sort of technology: "*culture*" (Geertz, 1973, p. 5).

The next section examines the practical features of culture formation in peer production communities, where knowledge is no less "*localized, embedded, and invested in practice*" than in the corresponding case of firms (Carlile, 2002) – but where "*integrating devices*" and "*representational capacity*" are perforce more explicitly artificial.

## 4.5 Architectures for collaboration

In Aaron Krowne's overview of the principles that informed the design of PlanetMath in its original incarnation, he states:

> *The basic, universal goals of digital libraries are to provide a logically organized, conveniently accessible, and (if possible) easily **actionable** collection of digitized **knowledge** in some field or fields for an audience of **learners**.*
>
> (Krowne, 2003B), original emphasis

As we've retraced his steps in the Planetary project, we've had the opportunity to re-examine the huge amount of often pioneering technical work that went into Noösphere. This work was nevertheless "of an era" – an era that can be understood more completely with reference to two other CBPP-related projects that started around the same time: Wikipedia/MediaWiki (Barrett, 2008) and Drupal.org/Drupal (Melançon et al., 2011). The key point, as we reflect back on the foundations of PlanetMath, is that there was a certain way of working, and indeed, a certain *theory of collaboration*, implicit the early architecture. The most noticeable tenets of this theory were associated with practices for "*homesteading the noosphere*" (Raymond, 1998) – namely object ownership and the corrections system. These features set PlanetMath apart from Wikipedia, and situate it closer to the typical practices associated with open source software.* PlanetMath, Wikipedia, and Drupal.org are all concrete examples of large postmodern organizations, built by many individuals who are asynchronously updating a shared database. The software systems behind the websites define and delimit many of the connections and boundaries between people, topics, and goals; *cf.* (Siemens, 2005), (Star & Griesemer, 1989).

**Building large knowledge bases by mass collaboration** The framework presented in Table 7 comes from Matt Richardson and Pedro Domingos (2003), who wrote about the particular challenges of building large knowledge bases through a process of mass collaboration. They also propose a specific approach to this problem, which cannot be given the same level of acclamation as their theoretical framework: it is hard to imagine inputting rules and facts as Horn clauses as a particularly popular pastime. The framework can be usefully applied to describe the process of "*building a digital library the commons-based peer production way*" (Krowne, 2003B), and, by extension, used as a lens for examining the social-technical-computational systems that *do* peer production.

Krowne's paper shows that a distributed approach can directly help to satisfy the criteria listed by Richardson and Domingos. For example, when compared with a centralized approach, commons-based peer production can help with *relevance*, insofar as:

* *Cf.* HTTP://DRUPAL.ORG/PROJECT/PROJECTAPPLICATIONS

**Relevance.** *In a distributed setting, ensuring that the knowledge contributed is relevant – and that volunteers' effort is productive – is a* [...] *significant problem.*

**Quality.** *Ensuring the quality of knowledge contributed by many different sources, when little is known about most of them, is likely to be very difficult.*

**Scalability.** *To achieve its full potential, a collective knowledge base must be able to assimilate the work of an arbitrarily large number of contributors, without the need for centralized human screening, coordination, or control becoming a bottleneck.*

**Consistency.** *As the knowledge base grows in size, maintaining consistency between knowledge entered by different contributors, or even by the same contributor at different times, becomes increasingly difficult.*

**Motivation.** *Following the example of open-source software, collective knowledge bases should allow user-developers to enter knowledge that is first of all relevant to solving their own problems.*

**Table 7:** *Criteria from Richardson and Domingos*

> [K]*nowledge is distributed unevenly and/or widely; a centralized effort can be inflexible; experts may be too busy with other work to commit entirely; and digital library builders themselves are not experts.* (Krowne, 2003B)

**The architecture of theories** To better understand the theory of collaboration underlying sites like PlanetMath, it is useful to enlist the help of Charles S. Peirce, who began his 1891 paper on "The architecture of theories" with a critique of those theories built from one idea, as if they were "*houses made of paper*" (Peirce, 1891). This would seem to be an especially important point for theorists of mediated collaboration to consider. A more recent critique focused on overly-constrained paradigms for the learning technology sector was advanced by Bernard Lisewski and Paul Joyce (2003), who argued that "*there are inherent dangers in them becoming too dominant a discourse*" or "*grand narrative*." They repudiate the uncritical use of theoretical systems. Table 8 shows how the framework proposed by Richardson and Domingos applies to the systems in operation at PlanetMath, Wikipedia, and Drupal.org. This table offers reassurance that each project has several important contributing ideas. Even so, a system needs to keep evolving in order *not* to become monolithic; *cf.* (Peirce, 1891).

**Dictionary vs Encyclopedia** Umberto Eco (1986) talks about written works that are organized along the model of the *Porphyry tree*, and works that are organized along the model of the *rhizome* or *labyrinth*, echoing (Deleuze & Guattari, 1980, pp. 5–7). Elsewhere, Deleuze emphasizes the associational aspects of cultural systems.

|---|---|---|---|
| **Relevance** | Relevance depends on peer review, and irrelevant content may be deleted. The mechanisms that would ensure that relevant content *will* be added need improvement. | People contribute articles about what they're interested in; apart from this, rules like WP:WEIGHT come into play. | Anyone can upload projects, although "full projects", require one time approval. Changes to the core require more vetting. |
| **Quality** | Quality control is handled with corrections and the "orphaning" mechanism in case of nonresponsive authors. Some articles are world-writeable, as in the wiki model. | Automated tools for spam and vandalism detection combined with a system of editorial oversight, in which Jimmy Wales has last say. | In addition to bug reports and feature requests handled through the issue tracker, modules can make use of an automated patch testing system. |
| **Scalability** | Peer review is distributed. Links are handled automatically. Caching is deployed where relevant; in particular, interlinking features are kept up to date. | The database and other infrastructure is massively scaled. There are many bots that help with small tasks. | In theory, anyone can join. Earl Miles, NYC-Camp 2012 keynote: "*There are no insiders, except Dries; there are no outsiders, only resumes.*" |
| **Consistency** | Although automatic links and corrections can help with consistency, mainly PM relies on standards for proof and expository quality. | NPOV is the key rule, which works together with templates and other process tools to maintain community standards about style and content. | The project issue queues are the place to go when one module's changes breaks another's. The core of the project has considerable oversight in these matters. |
| **Motivation** | People are solving some of their learning, exposition, and social needs on the site by writing and reviewing articles and posting in the forums. | As of 2006, over 50% of the site had been written by less than 1% of the users; these days, paid editing is somewhat notorious. | Miles continued: "*To build a resume, find someone who needs help, and help them. Find something that needs doing, do it.*" |

**Table 8:** *Criteria from Richardson and Domingos applied to describe three communities where mass collaboration happens (PlanetMath, Wikipedia, and Drupal.org)*

> [Hume] *gave the **association** of ideas its real meaning, making it a practice of cultural and **conventional** formations* [...] *rather than a theory of the human mind. Hence, the association of ideas exists for the sake of law, political economy, aesthetics, and so on. People ask, for example, whether it is enough to shoot an arrow at a site in order to become its owner, or whether one should touch the spot with one's own hand. This is a question about the correct association between a person and a thing, for the person to become the owner of the thing.* (Deleuze, 1953), original emphasis

Is PlanetMath best approached as an associationist dictionary or as a rhizomatic encyclopedia; *cf.* [§2.3, p. 30]? The specific example of *ownership* mentioned above is quite relevant in forming a prognosis. Following Raymond (1998), ownership after the Lockean property model was an important consideration in the design of PlanetMath/Noösphere (Krowne, 2003A, p. 5). As James Leach explains, in the Enlightenment tradition after Locke,

> *Human society is based on the ownership of property, as relationships between individuals **came into being** because of the appropriation of resources and the need to institutionalize that appropriation.* (Leach, 2007, p. 105), original emphasis

This way of thinking is based on the "*separation of spirit from matter, of appropriator from the substance appropriated*" (Leach, 2007, p. 105).* As described above [§4.1, pp. 47-48], this kind of thinking can truncate or distort important features of adaptivity. If "[t]*he knowledge needed to make land productive is part of a complex arrangement in social groups, and between them, whereby land and people become parts of one another*," and if people, more so than property, are "*the projects of other people*" then one "*distinguishes himself and gains authority through connection, not through exclusive control*" (Leach, 2007, pp. 111–112). At the very least there are some ideas here worth considering.

The next section treats other issues to do with relationship, community, and motivation that have relevance to paragogy.

## 4.6 Building online communities

Communities are often places where smaller communities form and dissolve again when their purpose has been served – recall the small naturally asynchronous groups of Goggins et al. (2013). One initial hypothesis that could help to understand communities is that they are most attractive when they work in a recursive fashion: *i.e.* healthy communities help their participants to develop sub-communities. In "Participation in an online mathematics community" Tausczik and Pennebaker (2012) use a framework adapted from Dholakia, Bagozzi, and Pearo (2004) to describe the reasons people participate in the research-level online mathematics community, MathOverflow (Table 9).

*Quoting (Pocock, 1985, p. 43).

| *Getting information* |
|---|
| *Giving information* |
| *Reputation building* |
| *Relationship development* |
| *Recreation* |
| *Self-discovery* |
| *Constructive Feedback* |

**Table 9:** *Criteria from Tausczik and Pennebaker*

Tausczik and Pennebaker examine each of these various motivations, using MathOverflow's built-in stigmergic mechanisms (score, downvoting, accepting answers, and comments) together with a textual analysis of comments conducted using the Linguistic Inquiry and Word Count (LIWC) methodology (Pennebaker, Francis, & Booth, 2001), which connects psychologically meaningful words to activities representative of each motivation.

Their findings report that "[t]*he strongest, most consistent evidence was found for the importance of reputation building in encouraging contributions*" however, there was only "*weak evidence that relationship building acted as an incentive to contribute*" and indeed that it "*may be another form of reputation building*" (Tausczik & Pennebaker, 2012). They emphasize the motivating features of concrete "*social benefits*," similar to Benkler's (2006a, 2002) notion of "*social-psychological rewards*." The model used on sites like MathOverflow seems to be an updated version of Eric Raymond's (1998) perspective: he suspected that "*the reputation-game gift culture is the globally optimal way to cooperate for generating* [...] *high-quality creative work*."

This would tend to go against the recursive hypothesis advanced above. Nevertheless, following Bateson, it is clear that relationships of one form or another are required in order for MathOverflow to support learning. The key point is that these relationships may be what Karin Knorr Cetina calls "*postsocial*" (Knorr Cetina, 1997): relationships not with people, but with mathematical objects and a distributed process of inquiry.

**Personal motivations** Daniel Pink (2010) believes that external rewards are often simply distractions, and proposes a theory of motivation based on "*autonomy*," "*mastery*," and "*purpose*." Thomas Malone (1981) advances a related framework for building motivating learning activities based on elements of "*fantasy*," "*challenge*," and "*curiosity*."

**Building new online communities** Even if all users are not motivated to participate in community-buliding activities, some are – and some may participate even without an explicit motivation. It is worth mentioning some points of alignment between Table 9 (particularly, reputation building and relationship development) and the advice from Resnick, Konstan, Chen, and Kraut (2012), who make these pragmatic suggestions to aspiring community builders:

> *– Drawing attention to external publicity and endorsements can raise expectations about future success.*
> *– In synchronous spaces that are not always active, a schedule of 'expected active times' coordinates visitors and can become a self-fulfilling expectation.*
>
> (Resnick et al., 2012)

**Almost Wikipedia** "Almost Wikipedia" was a thought-provoking talk given by Benjamin Mako Hill (2011A) at Harvard's Berkman Center, in which he says, in order to be as successful as Wikipedia, you should first make something people are familiar with – and second, make it easy for them to contribute.* In these terms, rebuilding PlanetMath as a collection of peer produced mathematical textbooks would make a good amount of sense. Sub-communities would also be readily recognizable (*e.g.*, "the authors of the Calculus textbook", *etc.*). In a recent paper, Hill and Monrey-Hernández (2012) point out a related finding: "*attributes of works associated with increased generativity are associated with decreased originality, and vice versa.*" Something that is easy to understand – and is, in that sense, perhaps not so novel – will be relatively easy to build upon.

## 4.7 Other related frameworks

Gregory Bateson explained the existence of a class of parallels arising in "*communicational and organizational process*" by reference to the "*the mysterious and polymorphic relation between context and content*" (Bateson, 1972, p. 163). There are many frameworks in the broader space of learning, communication, and organization theory that bear some analogy to the paragogy framework. These include Bateson's own criteria of mind (Bateson, 1980, p. 92 *et seq.*), and the functional framework of social movement theorists in the tradition of Luther Gerlach (Palmer, 2007). In short, if the paragogy principles are a rediscovery, they appear to be a very common one. As Harman (2008) remarks, "*anyone who looks seriously for fourfolds will start to find them everywhere*," and the same seems to go for 4 + 1 or 3 + *n*; *cf.* Genosko (2002, pp. 217–226).

The analysis that follows will draw upon some of these approximately-parallel frameworks, including: Pease and Martin's (2012) interpretation of Imre Lakatos's (1976) categories of mathematical activities, which is discussed in Chapter 7; Marshall McLuhan's tetrad of media effects (McLuhan & Powers, 1989), which is used to examine new features of Planetary in Chapter 8; and Stafford Beer's criteria for viable systems (Beer, 1981), which helps to frame discussions around projects in Chapter 9. In introducing the cybernetic notion of culture that was adopted in Chapter 1 [§1.4, p. 9], Geertz explained his motivations – which continue to apply here:

> [W]*e need to replace the "stratigraphic" conception of the relations between the various aspects of human existence with a synthetic one; that is, one in which biological, psychological, sociological, and cultural factors can be treated as variables within unitary systems of analysis.* [...] *It is a matter of integrating different types of theories and concepts in such a way that one can formulate meaningful propositions embodying findings now sequestered in separate fields of study.* (Geertz, 1973, p. 44)

*HTTP://CYBER.LAW.HARVARD.EDU/EVENTS/LUNCHEON/2011/10/MAKOHILL

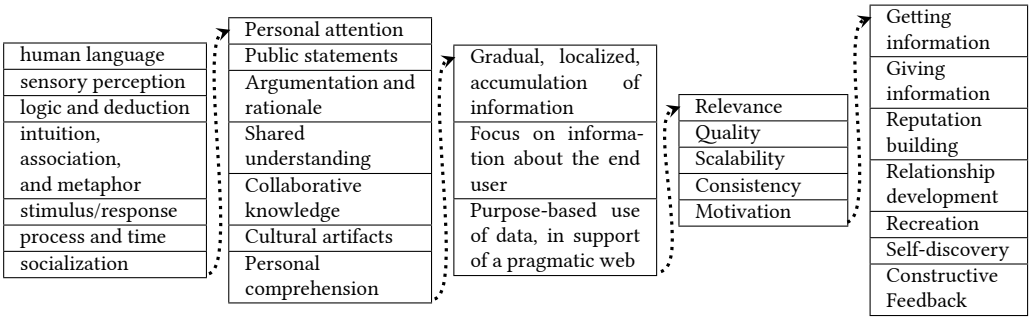

**Figure 6:** *Links between the key dimensions coming from the literature*

## 4.8 Summary

This chapter has contextualized the key pieces of research literature that are relevant to peer learning and peer production in mathematics. The framework provided by paragogy allowed a wide net to be cast, and provides an initial set of interlinked dimensions to consider when building a software model or further developing a paragogical approach in mathematics.

Arguing against any overly simple *narrative*, the aim has been to give paragogy a useful *form*. One possible instantiation is presented in Figure 6, which pulls together the main thematic ideas from the central figures discussed above, and shows that they fit remarkably well in a hierarchy. Socialization is important to Thurston: how does it work? This is explained by Stahl. And Stahl's critical personal comprehension? Perhaps this is built in a ecological way, as with the systems considered by McCalla. These rely on the idea of a pragmatic web, which could be described in terms used by Richardson and Domingos. Finally, the system as a whole is fueled by motivation, which has been examined in detail by Tausczik and Pennebaker. Whereas Maslow (1943) would presumably say that mathematics is pursued by generally healthy individuals as part of their efforts at self-actualization, this figure provides a more refined view. The relevant behaviors are inherently social – and the development of mathematics takes place across individuals. What we typically think of as the life of the mind may simply be "*the cutting edge of the life process itself*" (Ingold, 2000, p. 19).

Notice that the picture does not include the word "mathematics." It is possible to be more specific by thinking about how this scheme works in the mathematics case. After Halliday, understanding mathematics as a semiotic domain suggests that the core processes are not simply concerned with abstract symbol manipulation, but with making meaningful experiences. And after Bateson, it's clear that this requires the voicing of $\mu$ functions in which meanings can subsist. What is at stake in taking this forward is the matter of "*becoming relational*" (Durie, 2006, p. 183).

# Part 3
# Methodology and preliminary studies

# 5 Methodology

**The core research methodology aims to build a "thick description" of mathematical social life in the form of a working system for peer produced peer learning.**

## 5.1 The importance of building a working model

The following chapters examine "*man-made information sources for the directive ordering of human conduct*" (Geertz, 1973, p. 251) under conditions of emergence. This work retraces the layers of mediated sociality that were reviewed in Chapter 4: however the methods that will be applied are generally quite different from those of the authors examined there. Chapter 6 will exhibit a method for modeling the social antecedents to learning using statistical analysis. This is not a conceptual model of learning, but a way of showing, on average, what kinds of mediated acts bring about or catalyze learning outcomes. Chapter 7 uses focus group and interview-based methods to try to understand what potential users of PlanetMath would consider to be pragmatic for their purposes. Chapter 8 describes the design and development of the Planetary system, which is intended to be feature complete relative to Noösphere, with some key differences that that make it more suitable for peer learning applications. In Chapter 9, motivations to use PlanetMath/Planetary are investigated through discourse with users, who are involved in thinking critically about the affordances and limitations of the software. Research project does not focus on the processes of proof invention, heuristic discovery, and good old fashioned textbook problem solving, with which mathematical social life is often occupied, but rather the matrix in which these activities can be embedded. This does not mean that day-to-day mathematical activities are construed to reduce to a determination from the macro level (DeLanda, 2006A, p. 5) any more

than we would say that the theorems of Euclid or Archimedes derive from the floor plan or scribal practices at the Library of Alexandria. A emergent multi-layered approach, after (DeLanda, 2011) engages mathematicians and others in thinking carefully and critically about the "*the basic mental infrastructure of mathematics*" (Thurston, 1994), which as Chapter 4 has shown, has important social and cultural dimensions. Frayling (1993) describes "*Customising a piece of technology to do something no-one had considered before, and communicating the results*" as an example of "*research through art and design.*" This is a crucial aspect of the approach taken here, however, as the current effort aims to produce an actor-oriented model, what is most important is that the development of a prototype opens the way to consultations with users about the customizations they would like to see made. The findings comprise key steps on the way to the "*thickest possible description*" (Ryle, 1971) – in this case a software system that the research subjects would not only recognize as a reasonable account of relevant social experiences in mathematics, but which at least some of them would ultimately find useful. The thematic focus of the project as a whole is on software development in a social context. This approach affords the opportunity to build and jointly critique a working model of mathematical social life.

## 5.2 Review of primary methods

### Microgenetic analysis: studying the process of learning

Open online learning environments provide researchers with access to most if not all of the data that participants use to communicate with one another (Stahl, 2006); *cf.* [§4.2, p. 50]. These data can provide detailed evidence of learning and development. This kind of data – and the informal, *ad hoc* interactions that generate it – matches many of the ideas and techniques of *microgenetic analysis*. The microgenetic approach studies learning as a process, rather than the outcome of a process (Lavelli, Pantoja, Hsu, Messinger, & Fogel, 2005). The approach aims to examine moment-by-moment changes, often observed over a hort period of time, and often across a high number of separate observations, but not necessarily subject to the same staged treatment patterns found in longitudinal studies. Observations tend to be analyzed intensively, both qualitatively and quantitatively. In particular, microgenetic approaches have been used to take into account the social process of development in which individuals learn concurrently in a distributed fashion (Fischer & Granott, 1995). Broadly speaking, microgenetic analysis seems particularly well suited to our informal peer learning context, where a pre-test/post-test method for assessing learning quality would be inappropriate or unfeasible. The study in Chapter 6 can serve as a proof of concept illustrating the microgenetic measurement of learning, as adapted to the PlanetMath setting and dataset. Statistical

analysis of this sort of data presents some unique challenges (Cheshire, Muldoon, Francis, Lewis, & Ball, 2007). One particular challenge for modeling is that some users may not log in for long periods at a time, and may be strongly motivated in short bursts of activity; *cf.* (Barabási, 2005).

Chapter 6 examines additions and modifications to the PlanetMath encyclopedia taking place between Oct 6, 2001 and Dec 16, 2010, along with forum posts and corrections made during this time. The population of interest is comprised of the 445 people who made edits to the encyclopedia in this time frame. For the purpose of the study, changes to the encyclopedia in which a contributer uses a new word (on a per-person basis) is the outcome of interest. The analysis is based on a recently developed statistical method that is well-suited to handle bursty dynamics (Teravainen, 2014).

## Focus group and field work: Gathering user desiderata

Learning about and responding to users' design criteria is well studied in software engineering, where this is usually referred to *requirements analysis*.

> *Project participants or stakeholders may assign to the design object one or more goals – optative statements describing a change in the environment that the design object is desired to produce. A* ***requirement*** *is a feature of a design object that is necessary to achieve a goal.* [...] *More generally, suppose g may be achieved by n design objects* $(D_1, D_2, \ldots D_n)$ *each with features* $(F_1, F_2, \ldots F_n)$*. The set of requirements* $R_g$ *may then be defined as the intersection of the properties* $(R_g = F_1 \cap F_2 \cap \ldots \cap F_n)$. (Ralph, 2013)

In Chapter 7, I focus on what Ralph (2013) terms *desiderata*, rather than requirements. Chapter 8 revises this material into a minimal intersection of features for which the term *requirements* is more appropriate. In initial fieldwork, I aimed to understand users' goals, especially, but not only, the ones that could be achieved using software. At implementation time, a minimal kernel of features was developed, although this had as much to do with the limitations of time as with the empirical structure of user goals.

Chapter 7 is built around a focus group with fellow postgraduate students, and a brief period of field work and interviews with domain experts. This chapter uses the paragogy framework from Chapter 3 to map out the dimensions of change that seemed most relevant to these individuals as representatives of their respective stakeholder groups (students, mathematicians, and researchers with an interest in mathematical practice). The choice of populations to work with approximately follows (Corneli & Mikroyannidis, 2012). Inspired by Geertz, I adopt an interpretive perspective.* I relied on the idea of coherent change as an interpretive principle. The questions I returned to with research

*"[I]*nterpretation in my view is fundamentally about getting some idea of how people conceptualize, understand their world, what they are doing, how they are going about doing it, to get an idea of their world.*" Clifford Geertz, quoted in (Panourgía, 2002); reprinted in (Panourgía & Marcus, 2008).

subjects were "Would you find this sort of tool suitable for use in your work? (And if not, how would it have to change in order to be useful?)" The aim at this stage was to engage stakeholders in brief critical discussions about the potential usefulness of PlanetMath, from which I could extract a range of "*optative properties*" (Zave & Jackson, 1997). Statements about PlanetMath were also, explicitly or implicitly, statements about the stakeholders themselves.

For the initial focus group, 6 participants were recruited via email sent to the postgraduate student mailing list at the Open University (which reaches a population of around 250 local postgraduate students), and with an in-person announcement at the weekly postgraduate forum at the Centre for Research in Computing. The respondents, who as it turned out, were all from the computing department and who were all known to me previously, met in one focus group. I was able to make an audiovisual recording of the one-hour meeting. After a short presentation about PlanetMath, participants were asked to discuss three sets of questions in a variant of the "fishbowl" format.* Participants were divided into two sub-groups of 3 persons, who then were seated facing each other, at either side of a table. Group A was comprised of individuals who self-identified as "more mathematical" and Group B of those "less mathematical" in terms of their research interests and background. First Group A discussed a set of questions, while Group B listened, and then Group B discussed these questions while Group A listened. This design was employed to help ensure that everyone had a chance to talk, and to let differing views develop in the relative secure context of in-group dialog. The three sets of questions were increasingly vague, aiming to elicit exploratory interpretation on the part of participants (Figure 7). Each of the two-part rounds lasted 15 minutes. Participants were also asked to complete a brief questionnaire, which included space for free-form feedback.

My field work with domain experts again began with a presentation about PlanetMath, this time taking part in a seminar series at the School of Informatics at the University of Edinburgh. My primary contacts, a mathematician and a researcher who studies mathematical practice, who had both agreed to do interviews with me, were in the audience. During my four day research visit, discussions often happened in public (for example, after the seminar, or at a restaurant), and in the first private interview, the interviewee preferred not to be recorded. During the four-day visit, I therefor relied for on a daily journaling protocol as a way to create a record of what I was learning. This protocol (Figure 8) was adapted from a set of questions in a follow-up email from one of the ("less mathematical") participants in the initial focus group. Selections from the video transcript from the focus group and sources for quotes appear in Appendix C, and brief sample excerpts from my field notes in Appendix E.

*HTTP://WWW.CO-INTELLIGENCE.ORG/Y2K_FISHBOWL.HTML

**First set of questions ("Easy")**

- Would you find this sort of tool suitable for use in your work or studies?
- If you're an instructor, how might you have to change your teaching or assessment strategies if PlanetMath becomes popular?
- If you're a student, how might PlanetMath change your study strategy?

**Second set of questions ("Medium")**

- How do you currently solve problems?
- What do you do if you get stuck?
- What tools and strategies do you use to learn?

**Third set of questions ("Hard")**

- Describe your learning style.
- How do you deal with people whose viewpoints are very different from yours?
- How important is it to you to "own" what you create?

**Figure 7:** *Questions for discussion, posed to participants in the initial focus group of post-graduate students*

1. What were your key hypotheses at the start of the day?
2. How did you analyze the data you collected?
3. How did the results change what you knew before?
4. Did any of your hypotheses get corroborated as a result of your data analysis? If so, which, why and how strongly?
5. Did any of your hypotheses get challenged as a result of your data analysis? If so, which, why and how strongly?
6. Did you create or encounter any new hypotheses during or after the day's events? If so, please specify what they are and how you are going to test them.
7. How did any of the hypotheses relate to learning?
8. In hindsight, which questions proved to be the most or least salient?
9. Followup studies?

**Figure 8:** *Outline of journaling protocol*

## A basic grammar for interaction

Table 10 presents a summary of PlanetMath's *entity relation diagram* ("*ER diagram*"), showing the kinds of interactions that will be supported in PlanetMath/Planetary.* The research agenda is rooted in the idea of iterative development, whereby the basic interaction design will gain additional detail and expressive thickness.

Hence this central methodological proposition:

> A sufficiently extended version of the "grammar" presented in Table 10 should be able to transform mathematical texts and interactions into computationally accessible objects in a coherent way.

The five-fold division in Table 10 is again inspired by the paragogy principles from Chapter 3. Although the table provides a useful initial plan for implementation, from the point of view of modeling mathematical behavior, it is certainly not complete. For instance, one rather simple extension to the table would add subscripts to the arrows to code for the different agents involved – this would be needed for modeling the use case described in Figure 3 [§2.3, p. 31], for example.

To narrate the table's current entries: the encyclopedia, made up of interlinked articles and concepts provides the central/decentered shared context. The simplest kind of contextual glue is relatedness.† A link $A \overset{\ell_1}{\leftarrow} A'$ between two articles is only useful if the two articles are, indeed, *related*. Here, $A \overset{\ell_1}{\leftarrow} A'$ denotes a connection from $A'$ to $A$ via a standard hyperlink, whereas $A \leftarrow A'$ means that article $A'$ has been added as an attachment to article $A$.

| Context | Feedback | Quality | Structure | Heuristic |
|---|---|---|---|---|
| $A \leftarrow A$<br>$A \overset{\ell}{\leftarrow} A$ | $X \leftarrow T$<br>$S \leftarrow R$ | $X \leftarrow Q$<br>$A \leftarrow C$ | $A \leftarrow P \leftarrow S$<br>$L \leftarrow A, P$<br>$M \leftarrow A$<br>$Q \leftarrow A$ | $S \leftrightarrow H$<br>$G \leftrightarrow U$<br>$Q, T \rightharpoonup C, W, P$ |
| $A$ article<br>$\ell$ link | $X$ object<br>$T$ post<br>$S$ solution<br>$R$ review | $Q$ question<br>$C$ correction | $P$ problem<br>$L$ collection<br>$M$ classification | $H$ heuristic<br>$G$ group<br>$U$ user<br>$W$ request |

**Table 10:** *A paragogical decomposition of PlanetMath's activities: "production rules" in the grammar of mathematical behavior*

* *Cf.* Figure 1 [§1.4, p. 12].
† *Cf.* Nowak's rules of the evolution of collaboration [§4.4, p. 59].

Learning can happen in many ways on PlanetMath, but learning about learning seems most likely to be mediated by informal feedback, and developed in informal discussions. On the other hand, quality control develops through more structured peer review. Problem solving applications represent another layer of semantic structure. Deeper organization is driven by the use of heuristics, embedded in problem-solutions ($S \leftarrow H$), currently in a way that makes them hard to extract. Social heuristics involve purpose-created groups that solve problems together. Finally, these processes are accompanied by a curatorial or administrative process that mutates informal discussion into objects with more explicit meanings in the system ($Q, T \rightharpoonup C, W, P$). Time flows from left to right for all of these expressions. The table suggests various vectors of data on user activities that could be pulled out of the database: *new links between articles added*, *new questions asked*, *new corrections submitted*, *new problems proposed*, *new group memberships activated*, and so on. Rebuilt on this design, PlanetMath will become a large-scale recording device for interactions related to learning mathematics. In addition to mathematical relationships between articles and other objects, the "production rules" in Table 10 serve to code for various features of human collaboration. For example, by attaching a comment to an object, the user collaborates with the object creator by offering feedback. By attaching a correction to an article, the user collaborates not only with the original author, but more broadly with the readership, by helping to maintain quality and consistency throughout the encyclopedia. Attaching a problem to an article or organizing a set of articles and problems in a collection helps to structure the corpus, creating a small subarea with coherent meaning. People can use groups to collaborate as co-authors or in *ad hoc* teams. Collections and groups are also useful for specifying and sharing learning and production goals, and for breaking them down into smaller components. Chapter 8 describes the development of the Planetary system, which progressed along the lines indicated by Table 10, and further informed by the findings from Chapter 7. Chapter 8 uses Marshall McLuhan's (1989) tetrad of media effects to highlight the differences that the implemented features are expected to make.

## Design patterns and emergent design

Peer production is not a panacea. On the one hand, "*many successful peer production projects exhibit strong inequalities of participation and deeply entrenched leadership*" (Shaw & Hill, 2014). On the other, many free/open software projects never attract collaborators at all: "[t]*he benefits of collaboration become something to understand, support, and work towards, rather than something to take for granted*" (Hill, 2011b). This challenge will be approached here in a methodical way through the use of *design patterns* to describe problems and develop solutions within a paragogical context. This application of design patterns extends David Cavallo's (2000b) thinking about the *emergent design* of learning environments, rendering it somewhat more systematic.

**Title**: Encapsulate the idea – possibly include a subtitle.

**Definition**: Explain the idea and the context in which it is meaningful.

**Problem**: Explain why there's some issue to address here.

**Solution**: Talk about an idea about how to address the issue.

**Challenges**: Talk about what can go wrong.

**What's Next**: Talk about specific next steps.

*Examples, Illustrations, Objectives, and References are optional.*

**Table 11:** *Pattern template from the* Peeragogy Handbook

Christopher Alexander first introduced design patterns as part of an holistic approach to architecture, urban planning, and construction (Alexander, Ishikawa, & Silverstein, 1977; Alexander, 1979). The design pattern methodology spread from architecture to software (Vlissides, Helm, Johnson, & Gamma, 1995; Coplien & Schmidt, 1995; Gabriel, 1996), and later, to other fields, including public affairs (Schuler, 2008) and education (Bergin et al., 2012). A relevant recent survey is included in (Kohls, 2013).

Alexander's patterns are presented in tree-like structure called a *pattern language*, ordered in a top-down manner from large-scale to small-scale levels of application, with each pattern presented in terms of a *picture*, a *context* (including links to relevant larger patterns), the *problem* that the pattern addresses, the *solution*, a *diagram*, and *links to smaller patterns* (Alexander et al., 1977, pp. x-xi). A relatively convincing implementation of Alexander's idea of patterns as a "*living language*" (Alexander et al., 1977, p. xvii) was realized with one of the earliest applications of wiki software developed by Ward Cunningham: the Portland Pattern Repository.*

Taking the idea of a pattern language as a point of departure, the *Peeragogy Handbook* (Rheingold et al., 2014) includes a catalog of patterns for peer production and peer learning that the authors discovered while working on the book. The patterns are presented using a template (Table 11) that is closely aligned to the structure coming from Alexander. Each pattern is essentially a short textual abstract, and describes an active dimension of the Peeragogy project. This emphasis on the active aspect is made particularly clear through the "What's Next" facet, which concretely links the patterns in the *Handbook* to the current activities being conducted within the aegis of the Peeragogy project. The *Newcomer* pattern is presented as an example in Table 12.

*HTTP://C2.COM/PPR/

***Newcomer: Welcoming "beginner's mind."***

**Definition**: Unless there is a new person to talk to, a lot of the "education stuff" we do could grow pretty stale. Many of the patterns and use cases for peeragogy assume that there will be an audience or a new generation of learners.

**Problem**: Some of the problems are well summed up with a quote:

> **Régis Barondeau**: I joined this handbook project late, making me a "newcomer." When I started to catch up, I rapidly faced doubts: Where do I start? How can I help? How will I make it, having to read more than 700 posts to catch up? What tools are we using ? How do I use them? Etc. Although this project is amazingly interesting, catching the train while it already reached high speed can be an extreme sport. By taking care of newcomers, we might avoid loosing valuable contributors because they don't know how and where to start, and keep our own project on track.

**Solution**: It is good to try to become aware of what a newcomer needs, and what their motivations are. Another quote can illustrate:

> **Charlotte Pierce**: Joe was working a lot on the book, and I thought "this is interesting hard work, and he shouldn't have to do this alone." As a Peeragogy newcomer, I was kindly welcomed and mentored by Joe, Howard, Fabrizio, and others. I asked naive questions and was met with patient answers, guiding questions, and resource links. Concurrently, I bootstrapped myself into a position to contribute to the workflow by editing the live manuscript for consistency, style, and continuity.

**Challenges**: Newcomers in the Peeragogy project have often complained about feeling confused, suggesting that our project roadmap may not be sufficiently clear, and that more work has to be done the project accessible. Even in the absence of actual newcomers, we need to try and look at things with a "beginner's mind."

**What's Next**: We recently revised the "How to Get Involved" page, listing the top ten sites we use. Another reasonable thing to post would be a top-ten list of activities, so that people can get an easier view on the kinds of things we do in the project.

**Table 12:** *The* Newcomer *pattern from the* Peeragogy Handbook

The main features of the Peeragogy pattern template are analogous to the paragogy principles [§3.1, p. 36]. The *definition* is meant to connect the pattern to a particular context; specifying the *problem* provides the opportunity to explain why there's something here to learn; a *solution* usually involves interactions with peers; *challenges* arise in practice due to the nonlinear nature of real-world problems; and writing down *what's next* indicates that after identifying a pattern, there is usually still work to be done.

This approach seems to be a novel interpretation of the design pattern methodology. For comparison: the Public Sphere project uses a detailed template to elicit input for their pattern catalog. They aim to distill existing, ambient, "*civic intelligence*" in an effective form.[*,†] However, although this pattern language continues to develop as a work in progress, the patterns are not explicitly linked to actions taken in the project. Table 13 presents a succinct overview of the Peeragogy pattern catalog, with references to the Minskian heuristics from Table 4 [§4.2, p. 53]. This helps to show how the Peeragogy patterns are relevant as a set of heuristics for social problem solving. Further details are in (Rheingold et al., 2014).[‡]

The Peeragogy project continues the tradition of reflexive research-through-writing that was used by Tomlinson et al. (2012). Both of these efforts used their own collaborative writing and research activities as primary sources of data. Building on this bootstrapped material, the application here is comparatively straightforward.

In Chapter 9, feedback arising in the user evaluation of PlanetMath/Planetary is analyzed in terms of the Peeragogy pattern catalog, and the catalog is extended with three additional patterns. In the work reported in Chapter 9, PlanetMath users were not involved directly in doing pattern-based analysis or coming up with new patterns: rather, I wrote new patterns based on what I learned in our interviews. In preparing the analysis, I used a "path metaphor" similar to that employed by Christian Kohls (2010, 2011), who describes patterns in the language of constrained optimization problems, considering the initial state, end state, and forces acting.

At the level of process: I successfully recruited 6 people who completed a 10 day study on PlanetMath that took place two months after the launch of the new software system. The participants were 3 PlanetMath users and 3 mathematics postgraduate students from the Open University. Two of the PlanetMath users had prior familiarity with PlanetMath/Noösphere, and two Open University Masters students were familiar with online distance learning. Four participants use mathematics professionally. (A seventh participant was recruited from the *Peeragogy in Action* Google+ community, but he disappeared before completing the planned tasks or an interview.)

[*] HTTP://PUBLICSPHEREPROJECT.ORG/PATTERNS/CHEAT-SHEET.PHP

[†] HTTP://WWW.PUBLICSPHEREPROJECT.ORG/TEMP/YOUCANHELP.PHP

[‡] And in the online version of the book, at HTTP://PEERAGOGY.ORG/PRACTICE/.

We *simplify* things for a **Newcomer**.

We *change focus* by using a **Roadmap** to guide us from one step to another. Every roadmap is associated with **A Specific Project**, and the specificity is important. In addition, the project's **Heartbeat** leads us to let go of our focus at one moment, and resume with another point of view later.

We *change description* first of all by having a **Wrapper** who describes the new state of the project. For the Peeragogy project, that often meant summing up the high points that we saw over a given period of time. It seems possible that with a rich enough **Pattern Language**, the description would itself be made in terms of patterns.

We *divide* work up not only "horizontally" among different **Roles**, but also "temporally" by using the **Roadmap**. Someone who is moving ahead with the Roadmap is likely to be "working at the cutting edge".

When we *find an analogy*, we are basically **Creating a Guide** of some sort. This can be used as a form of "exploration", as we look at how one form of engagement may or may not map onto other forms of engagement.

When we *ask for help*, we may avail ourselves of some **Moderation** service that will decide how to deal with our request. One simple way to ask for help is **Polling for Ideas**. Obviously once we start to get help, we're working in a regime of "collaborative effort".

If you *know the answer*, then you may be able to reuse it (which is the basic idea of **Use or Make?**). Someone who knows the answer and who is good at self-explanation may also have a good idea about how to get from the current state to the goal state; alternatively, this may be broken down into steps in a sub-**Roadmap**, and moving from step to step would then illustrate "progressive problem solving".

It is important to *give it a rest* so as not to over-exhaust oneself, busting one's own **Carrying Capacity**, or, alternatively, overwhelming the group.

It seems that one of the things that *experts do* is **Discerning a Pattern**. This allows them to simplify their processing.

Finally, again, if we *know why it is hard*, then we may be able to **Create a Guide** that will help get around, or at least better cope with, the difficulty.

**Table 13:** *Overview of the central patterns in the* Peeragogy Handbook

**(Step 1)** You'll join an hour-long online focus group, where I'll brief you on the tasks for the next step, and give a more detailed description of the study, as well as gather some initial feedback about the site in an open discussion.

**(Step 2)** You'll try out the new system features that we've developed – this can happen as you have time, over a week or two. We'll be able to talk about issues or concerns as they arise, in the PlanetMath forums.

**(Step 3)** You'll meet me with me for a small group or one-to-one interview to talk about your experiences with the system; this will again take less than an hour.

**Figure 9:** *Steps in the user evaluation (from an email sent to 30 high-scoring and recently-active PlanetMath users)*

The steps in the study are indicated in Figure 9. In an initial meeting held via Skype, I walked study participants through a set of screenshots from PlanetMath/Planetary (presented here in Chapter 8). As a set of tasks to complete over the next 10 days, I asked participants to try each of the features described in the screenshots. During the meeting, I also asked users to introduce themselves, and to describe their mathematical background. I suggested that they work together in case of any difficulties, attempting in this way to foster a peer learning culture within the group. Participants who didn't yet have PlanetMath accounts made them at the start of the study. Over the next 10 days, most participants tried many of the tasks, sometimes posting comments about their experience in the PlanetMath forums, and sometimes emailing me directly to ask for help. After the 10 day period had elapsed, I conducted individual follow-up interviews.

As in the initial study with stakeholders, the main question I focused on in the interviews was: would PlanetMath be relevant to the way you study and do mathematics? I also tried to elicit ideas that might help to improve the site, making use of shared familiarity with the system.

During the interviews, I took graphical notes and made audio recordings (when possible). Interview data was analyzed twice: first on a thematic basis, by connecting user feedback to the main dimensions of the design of PlanetMath/Planetary discussed in Chapter 8, and again by looking for matching patterns in the Peeragogy pattern catalog (Table 13). The idea in the pattern analysis was that either the existing catalog of Peeragogy patterns would describe the topics under discussion, or new patterns would emerge with links to the existing patterns showing how they are similar or different. In either case, a contribution will have been made to enhancing the usefulness and descriptive power of the pattern catalog.

## 5.3 Summary

The patterns that guide behavior in the PlanetMath context are related to historical mathematics practices, but are understood to have features that are emergent in the new setting. This invites a "DeLandan" perspective on culture that looks at the emergent dynamics within and across several levels of analysis. The primary methods are statistical analysis of historical data, qualitative field work, implementation of a software system for collaboration, and emergent design.

Several novel methodological points were introduced, including the simple idea of using vocabulary growth as part of a statistical model of learning in a technical domain, and the more complex idea of using design patterns to represent the heuristic, and emergent, aspects of paragogical projects. Paragogy was useful in developing an initial entity relation diagram for PlanetMath/Planetary, and new schemes for analyzing qualitative data. In this way, paragogy has been baked into the design of both the software system and the research process.

The overall aim is to do research through iterative development within an emergent design framework. A key limitation is that the following chapters are only *one* research cycle. This work necessarily focuses on the dimensions which are currently accessible to study, for example, "vocabulary use" as opposed to "heuristic use" – as well as the most basic technologies and use cases. The primary merit of the approach is that it opens the way to a participatory, computer-mediated, study of mathematical culture.

# 6 An Analysis of Learning Interactions in PlanetMath/Noösphere

**The first study focuses on understanding the effects of peer support on learning in the course of encyclopedia authoring activities and forum discussions on the original PlanetMath.**

## 6.1 The fundamental problem of instrumentation

This chapter looks at what causes a change in propensity to use new vocabulary words among contributors to the PlanetMath website. In addition to new vocabulary, in practice, there are of course many other nonlinguistic, embodied, behaviors that people learn when they learn mathematics. The statistical methodology employed here would be equally applicable to the effect of behavior on word use, or the effect of word use on behavior. The focus is not on the internal or embodied organization of learning, but on the social covariates, antecedents, and possible precipitating causes. The particular strength of the method that was employed here is that, unlike standard time series methods, this approach is designed to filter out effects that are due to "calendar time", like seasonality, leaving only effects that are tied to the "gap time" between events. The technique works with any pair of time series vectors, one representing the *treatments*, and one representing the *outcomes*.

From a qualitative perspective, describing a given antecedent, for example, giving instruction, as a "*cause*" of learning is rather thin: it may be better to speak of statistical effects as "*catalysts*"; *cf.* (DeLanda, 2006B). After all, we could always go back further, looking for earlier and deeper contributing causes. What the method used here shows is that there was a significant social contribution to learning in PlanetMath/Noösphere; and it shows the differential effect of two different catalysts.

Due to it's generality, the method exhibited in action here is a candidate solution to the fundamental problem of instrumentation: *how do we know if it's working?* For example, if we were to use PlanetMath to make recommendations, as in the use case from Figure 3 [§2.3, p. 31], we would want to know that the recommendations were having the desired effect. The method demonstrated here could help.

## 6.2 Design and related work

The study aims to demonstrate that peer interactions in PlanetMath/Noösphere had a tangible and measurable effect on learning outcomes. New types of interactions may produce vastly different, and stronger, effects. It will be important to have a framework for analysis that can be used to gauge the effect of these interactions on desired outcomes.

The study offers a preliminary quantitative analysis of learning on PlanetMath, using legacy data from the site's first 10 years of existence. Even though PlanetMath was not designed to function as a learning environment during this phase, by design it had an explicit "*pedagogic slant*" [§2.1, p. 21] andr it is reasonable to hypothesize that people were, in fact, learning through their interactions on the site.

It is important to mention that during this time period, the growth of the PlanetMath encyclopedia, and, in its metadata layer, an associated mathematics lexicon, was the key measurement of success. Practices of peer review and norms like "one definition per concept" and "proofs should be self-contained" afforded a degree of integration and rigor that would not be directly possible with a fully-distributed information source (like the blogosphere).

Learning new things and sharing existing knowledge were two possible motivations for contributing to the encyclopedia. In some sense the latter motivation would have to be typical for encyclopedia authors – although the two motivations are not mutually exclusive, as expressed in the adage "*The best way to learn is to teach*" (Luk & Wang, 2012).

Distinguishing between the use of new words at the personal and community levels might help to distinguish between these two motivations. Someone who often uses new words on a per-person basis that are not new on a community-wide basis may be a more typical learner. Someone who consistently adds globally new words is more likely to be an expository writer or researcher.

This study focuses on the use of new words on a per-person basis, without distinguishing the words that are globally new from those that are only personally new. The analysis focuses on the immediate catalysts for the use of a new word, comparing a self-

started effect (posting in the forum) and an other-started effect (receiving a correction). For the purpose of the study, any use of a personally new word is thought of as a positive outcome, and considered to indicate learning in some form.* Even if in many cases this is learning in the course of practicing something that one already knows reasonably well, it is interesting to understand the social catalysts for such practice.

In order to facilitate the comparison between the two effects, I processed all of the data describing contributions to the PlanetMath encyclopedia from the first 10 years of the website, and found the timestamped changesets where each user first uses a term that is part of PlanetMath's technical lexicon. These technical terms include the titles of articles, as well as synonyms noted by the author in article metadata. Along with this word usage data, timestamped entries in the database showing when authors had either posted in the forum or received a correction.

This data was then analyzed using the recently developed computational method from Timothy Teravainen's PhD thesis *Semiparametric Estimation of a Gaptime-Associated Hazard Function* (Teravainen, 2014), discussed in overview in (Wu et al., 2011). This work falls within the field of statistics known as survival analysis; *cf.* (Fleming & Harrington, 2011). The method estimates the increase in likelihood associated with the specified outcome (here, using a new word) after the treatment event (here, either the self-initiated treatment of posting in the forum, or the other-initiated treatment of receiving a correction). The change in likelihood is considered in comparison to a otherwise equivalent user who did not receive the treatment, and the results are averaged across all contributing users and all time.

For comparison: Albert-László Barabási's paper on "The origin of bursts and heavy tails in human dynamics" (Barabási, 2005) uses a large collection of email correspondence as a data source. Barabási's models use power law functions, which are generalized by the Ornstein-Uhlenbeck process at the core of the computational model employed here (Behme, 2011, p. 12).

There are many relevant techniques for dealing with social networks and time series data; *cf.* (Rajaraman & Ullman, 2011, Chapter 10), (Quenouille, 1949). Standard cross correlation is the most typical approach to studying time series data, but it cannot distinguish between gap time effects and calendar time effects. For this study, the typical gap time is of interest, rather than seasonal effects. Many modeling efforts consider only the relative *sequence* of events, discarding the timestamps – *e.g.* Abbott (1995) – but this approach is not well-suited to studying activities that are distributed over long periods with bursts of activity.

* *Cf.* Leung [§4.2, p. 51], Halliday [§4.2, p. 52] and Minsky [§4.2, p. 53] for some of the considerations involved with using vocabulary growth as a proxy measure for learning.

Various corpus techniques could be used to extract meaningful patterns from a text (Pustejovsky, Anick, & Bergler, 1993). Any refinement to the input data would be compatible with the statistical model used here, as long as the data can be mapped to a time series. Work with named entities is particularly straightforward and well-studied (Nadeau & Sekine, 2007). The LIWC, mentioned in Chapter 4 is an example of this sort of approach, and focuses on psychologically meaningful words, including pronouns, and words related to emotions and causality; *cf.* (Pennebaker et al., 2001).

## Methods

The last ten years of versioned encyclopedia articles were loaded into Git, which made it relatively easy to extract line-by-line differences between versions, using `git log` and `git show`. These change sets were analyzed using a term spotting approach, with technical terms drawn from the thesaurus-like metadata from PlanetMath's encyclopedia articles. This was done using *ad hoc* code implemented around a regular expression based search.* The functionality is similar to that of PlanetMath's autolinking tool, NNexus (Gardner, Krowne, & Xiong, 2006), and with a few changes to NNexus, the method used here could be readily adapted to make use of transcripted NNexus data. Subject to the general caveats above, that detected words may in many cases be exposition events rather than elementary learning events, the outcome of interest is any encyclopedia edit that includes a new word from the lexicon (per-user, considered relative to the history of their previous contributions to the encyclopedia). During the time period under observation (Oct 6, 2001–Dec 16, 2010) for the population of 445 "committers" under consideration – exactly the population of persons for whom we have edits on record – there were a total of 8051 forum posts made, 14064 corrections received, and 3867 modifications to the encyclopedia in which any non-zero number of new (per user) technical terms were detected.† The method applied to analyze this data was a slight variation on that studied in Teravainen (2014), in which the primary application was to sequences of events with a statistical self-retriggering property that did not present the need to distinguish between "treatment" and "outcome". Here, the computation first identifies gaps between treatment and outcome events, and then aims to estimate the effect that the most recent previous treatment had on a given outcome. It does this by fitting the data to a physical model with two primary dimensions: an initial impulse and a damping effect (an "Ornstein-Uhlenbeck process"). Teravainen considers stochastic generalizations of this model that were not applied in the computations here.

*HTTP://METAMESO.ORG/~JOE/MATH/THESIS-SUPPLEMENT/

†PlanetMath defines quite a few more than 3867 terms, and one might expect an aggregated per person usage statistic to be still bigger than the total number of terms available. The reason for a lower figure may be accounted for by clarifying just what was counted as a "usage event." First, articles can define multiple terms, and if multiple terms are introduced in one editing pass, then this would only count as one instance of "new word usage." Second, many articles have titles like "*proof of . . . theorem*" which never appear in the article's body, and which consequently wouldn't be detected in the changesets.

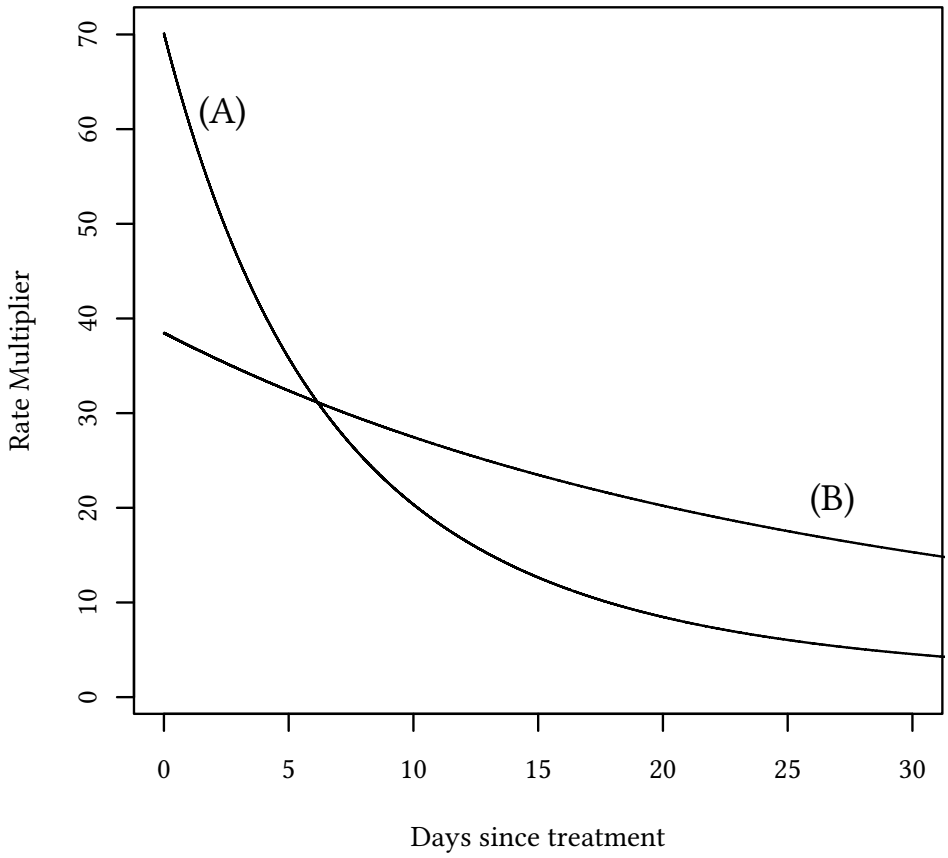

**Figure 10:** *A plot showing the differential effect of (A) an exogenous treatment* (receiving a correction)*, and (B) an endogenous treatment* (posting in the forum) *on* using new words in the encyclopedia

## 6.3 Estimating effects

Intrinsic self-motivation is a well-known catalyst for learning. It is interesting to consider the differential effect on learning outcomes from stimuli that are self-driven from stimuli that are initiated by peers. Two trajectories along these dimensions are examined:

**Trajectory A.** The effect of *corrections received* on *new technical terms used.*

**Trajectory B.** The effect of *posting in the forum* on *new technical terms used.*

Trajectory A is other-motivated; Trajectory B is self-motivated, but occurs within a social context. As shown in Figure 10, Trajectory A has a strong initial effect, but wears off relatively quickly, whereas Trajectory B has a much more moderate effect,

and wears off slowly. This suggests that people who are motivated to post in the forum are also motivated to keep adding new concepts in encyclopedia articles – and it also shows the strong value of peer support even among this self-selected group of highly self-motivated people.

## 6.4 Potential refinements

In the first place, without considering any semantic extensions to the underlying model, it would be useful to have confidence intervals around the curves in Figure 10. Such estimates are forthcoming.*

It would be useful to extend the model to study several different treatments in parallel; this could help to tease out the differential effect of a socially-motivated post in the forum *versus* an edit to the encyclopedia. At the moment, the model compares a given treatment to "no treatment"; it would be useful to be able to run more elaborate simulated control studies.

The current model does not make use of the "networked" aspect of the PlanetMath encyclopedia or the underlying social network. A more ideal model of an individual's learning patterns would consider the geometric features of the system that they are studying. It seems reasonable to hypothesize that person would be more likely to learn terms that are near terms that they already know, and especially likely to (serendipitously or opportunistically) learn things that are adjacent to topics they are currently working on. A simple prior distribution could be employed, saying that, all else equal, terms are most likely to be learned in proportion to their PageRank, or inversely in proportion to their mathematical depth (which could be estimated by other graph-theoretic distance from known elementary concepts).

Apart from modeling issues to do with personal learning history, the modeling problem is complicated by the fact that people are different from one another in ways that have nothing to do with the domain. One possible adaptation of the current scheme would use a Dirichlet prior that takes into account the fact that there are "different kinds of people." For instance, we could categorize users according to the apparent strength of their intrinsic motivation. Some users may require more attention if they are to stay involved. More broadly, we might want to consider individuals with a range of features, per (Broderick, Mackey, Paisley, & Jordan, 2011).

An alternative interpretation of the PlanetMath data would come from transposing the matrix, so that instead of looking at new-terms-per-user, we could look at new-users-per-term. This approach would useful for studying community-level linguistic change.

*Timothy Teravainen, personal communication.

Vocabulary growth has previously been studied with the aim of predicting user migration. According to Danescu-Niculescu-Mizil, West, Jurafsky, Leskovec, and Potts (2013), "[a]*fter an initial period of adaptation to the language of their community* [...] *individuals' language patterns slowly rigidify until the moment they abandon the community.*" It would be interesting to see whether there are explicit strategies for lifelong learning in a deep domain like mathematics that help maintain user interest.

It would also be interesting to look at the developmental course of learning: do individual users undergo intensive periods of learning, similar to the burstiness studied by (Barabási, 2005)? Do users learn new nonlinguistic behaviors along with new vocabulary, per (Iverson & Thelen, 1999)?

## 6.5 Summary

This chapter has employing a new statistical method to estimate the effect of two different treatments on learning outcomes. An analogous study could be performed in any context where learning can be modeled by vocabulary growth. This includes technical domains, and potentially any book with an index.

The significance of the approach is considerably more general, since, as suggested in principle by (Wu et al., 2011) and now illustrated here, the same techniques can be used to model the effect of any time-delineated series of "*blip treatments*" on a time-delineated vector of outcomes.

The techniques can be applied directly to study discrete online interactions that are likely to have effects on learning outcomes or other valued goals. With further refinements, this sort of analysis could inform varied diagnostic and recommendation services. Although these issues are not developed further in the thesis, this chapter does illustrate the potential usefulness of gathering varied data on user interactions, and this point is taken up again in Chapter 8.

# 7 Surveying Stakeholder Perspectives

**The second study employs qualitative methods to build a richer picture of the stakeholders in a peer learning environment for mathematics.**

## 7.1 Overview

The purpose of this study was to understand the perspectives on PlanetMath's rebuild from several likely user and stakeholder groups – students, mathematicians, and "reflective practitioners." The latter group is understood to include philosophers, social scientists, educators, and computer scientists whose work contributes to an "*inquiry into the epistemology of practice*" in the mathematics domain; *cf.* (Schön, 1999, p. viii).

Asking potential PlanetMath users what they would expect from a "peer learning environment for mathematics" offers the opportunity to learn something about what they think about mathematics *per se*, and to understand the role that computer-mediated communication plays in shaping their perspectives.

I have endeavored to convey the understandings that my research subjects offered in terms of the meanings that are operant for them in our conversations. The idea of PlanetMath constitutes a minor perturbation to the life-worlds of these research subjects; their framing of "the question" of PlanetMath is of particular interest.

> *A meaning-reaction is* [...] *a fitting adjustmental response which individuals acquire through the direct influence of the surrounding objects and conditions. It is in this way that a meaning-reaction becomes the means for bringing about an especially fitting adjustment of the person to his surroundings.* (Kantor, 1921)

In some cases, the subject's responses to PlanetMath, and what it represents, were enthusiastic – and in other cases, highly skeptical. Wherever these responses were not entirely explicit (whether they were favorable or unfavorable), I have expanded the discussion to help put them in context. For example, perhaps the most "interpretative" move on my part was to point out the connections between students' explicit mention of *trust* and the unspoken issue of *credit*.

At this point, it is not entirely appropriate to think of the collateral adjustments that are indicated for PlanetMath as "*requirements*" in the typical engineering sense; I have called them "*desiderata*," following (Ralph, 2013). The feedback elicited at this stage points to long-term goals that are not wholly realized by the implementation work described in Chapter 8. At the same time, the work presented in this chapter usefully conveys a sense both that this implementation work is "on track," and a meaningful indication of what it is pointed towards.

This research is based on a focus group I ran with 6 postgraduate students in computing at the Open University, and a 4 day research visit to Edinburgh, which was spent partly at the Department of Informatics at the University of Edinburgh and partly at Heriot-Watt. In Edinburgh, my primary informants – who have agreed to be non-anonymous in this report – were Murdoch James Gabbay and Alison Pease. I scheduled my visit at a time when I was also able to speak with Ursula Martin, Timothy Gowers, Mohan Ganesalingam, and Andrew Aberdein, and this chapter benefits from those discussions. From a practical standpoint, a standard of non-anonymity among the professionals I spoke with is justified because connections to published work are discussed in the chapter; from an ethics standpoint, this choice was seen as justifiable, since the points discussed were not contentious or especially personal. Had I been interested in a detailed ethnographic description of the lives of these informants, I would have opted to disguise the responses with pseudonyms.

Although the fieldwork methods used in the two settings were somewhat different – a "fishbowl" style discussion around my prompts in the student focus group at The Open University, and several days of relatively immersive discussions with professionals in Edinburgh [§5.2, pp. 71-73] – I have presented the findings in a uniform format. Inset quotes are paraphrases of things that respondents said; the relevant issues are then expanded in my own words. References [C1]–[C15] point to supporting data in Appendix C. The conclusions presented in the text were often, but not always, arrived at jointly with the research subjects.

The findings are presented in detail in the sections that follow, where they are mapped to the paragogical framework of dimensions of change from Chapter 3. A brief "composite" overview is presented just below.

### Student

As long as their university courses provide everything that current students are seeking, they are unlikely to use PlanetMath, even as an ancillary tool. And yet it seems clear that PlanetMath could be used as a form of alternative credentialization – through a transparent record of contributions, including problems solved – or as a textbook, or even as a course management tool.

### Mathematician

For a mathematics researcher, contributing to public discussions about mathematics is not typically done directly for the purpose of "getting credit" (as in, something to put on one's CV), but rather because it helps with research. There are many ways this could be better supported, both on PlanetMath and with tools that work across the web. Working in the capacity of instructor, a professional mathematician needs to help students learn relevant social as well as technical skills. One way to encourage this is to make suitably structured peer interaction a required component of courses. Some of these interactions could take place online.

### Philosopher

Philosophers of mathematics working within the empiricist tradition are interested in the ways in which understanding arises. This can be studied using various kinds of models, ranging from heuristic frameworks imposed over data generated through human interaction to computer simulations. Insights gained through this work can help to improve education, tool design, and can also contribute to the field of artificial intelligence. PlanetMath could be both a source of useful information, and a consumer of the philosopher's insights.

## 7.2 A student perspective

**Changing the nature of the space** The issue of trust was raised even before I had shared any details about which factors might already exist that might instill trust. This minor incongruity suggests that the issue of trust might be conflated with another deeper issue. I suspected that this was the issue of credit. In a university course, students can trust their instructors and TAs to adhere to clear contractual obligations. They can trust that if they put forth a reasonable focused effort, they will earn an appropriate mark. So it is clear that in the traditional university setting, trust and credit are closely linked. However, without explicit attention to creating suitable mechanisms, in online peer production systems, neither trust nor credit is there

> *"Can we trust the people who are contributing?"* [C1]

by default. Accordingly, systems for distributed production, including Q&A sites, open source software projects, and online encyclopedias – some to better effect than others – have all created their own mechanisms for building trust and maintaining quality [§4.5, p. 61]. It seems that trust and credit go well together online, as well as offline. If it is easy to see what someone has contributed, and perhaps what others thought about it, then it's also reasonable to expect their engagement will continue roughly in the same vein.

**Changing what I know about myself** Small moves with continuous feedback at each stage could help build the user's confidence. The feedback may reveal that they know the answer to the problem, for example – and if not, taking small steps means that the user is never too far from what they do know. Indeed, mathematics naturally breaks down into small steps, but it may not be obvious how this works for a beginner. Learning *how* to break a task down into small, individually-masterable steps is a useful skill, and can help make mathematics less daunting (Mighton, 2003).* Students also need to learn persistence, but persistence through many small steps is one route to this.† More broadly, teaching that mathematical ability can be developed through hard work tends to have a lasting positive effect (Dweck, 2000, 2007).

*"Does PlanetMath provide support for progressive problem solving?"* [C2]

**Changing my perspective** In what might be called instrumental problem solving, some piece of information is needed as soon as possible; it is of fleeting interest and limited application. In non-instrumental problem solving, the needs are in some sense simulational rather than informational. What is at stake is building a lasting mental model of how things work. The nominal use of an encyclopedia is for lookup – the encyclopedia can play the role of the model. On the other hand, peer interactions open up the world of non-instrumental problem solving. It would be possible to make a further distinction and say that instrumental problems can be solved *transactionally*, whereas non-instrumental problems can only be solved *interactionally*.

*"When I'm programming, I look up error messages online; but in my Calculus course, I don't want to ask a question until I've really thought a lot about the answer."* [C3]

**Changing content or connectivity** Participants had many ideas about how the site should give feedback – ranging from having hints available to building rich "*ontology of problems*." It

*"Are there good mechanisms for getting (and giving) feedback?"* [C4]

* *Cf.* Gowers [§4.2, p. 50] and Leung [§4.2, p. 51].
† Jim Pitman, personal communication

occurred to me that since they had many creative ideas about this, in the long run it would be as important to be able take new feedback on board as to give it out. A rich give-and-take of feedback gets to the crux of (non-provisionist) peer learning. Tools like Get Satisfaction* are the typical way to elicit and record users' ideas about system features. Of course, actually acting on the feedback tends to be the real sticking point, and the only way to keep feedback coming. Transforming a flow of often highly transient attention into usable code calls for deep consideration of "*the match between cognitive processes and the statistical structure of the environments in which they function*" (Dhami, Hertwig, & Hoffrage, 2004) – across rather different populations. A project usually will not look the same to programmers and end users; *cf.* (Aboulafia, 2012, §5).

**Changing objectives** One might hypothesize a class of environmentally-distributed problems that are too complicated to simulate easily, and for which the environment is the best model.† On this basis, an economics of problem solving begins to unfold that is reminiscent of Coase's (1937) theory of the firm. There is a class of problems that is best solved "in-house," by interacting with and developing one's personal mental models – because building the mental model is the real point. There is a class of problems where the answer can be retrieved from one's existing mental model. This is the standard case of *knowing* – or what might in a litigious frame of mind be called "intellectual property." There is a third class of problems that are best solved through a transaction with the environment, by lookup or search – in this case, the only aspect of the mental model that matters is knowing where, or how, to look. This is the connectivist's actionable knowledge.‡ And there is a fourth class of problem which is again best solved interactionally, but this time, by interacting with others after the model of the commons, rather than that of the firm – in a meeting of minds. In practice, it seems there will always be a degree of sociality, in the sense of being "*betwixt and between*" [§1.3, p. 8] – a savant will think for a moment before answering, for example. The relevance for PlanetMath is that some people will want to follow relatively well determined channels which offer reasonably assured results, whereas others will want to experiment with new models, or tackle problems with greater risks. Outside of compulsory education, the student is typically someone who wants to earn a credential of some sort, which puts some constraints on the degree of newness. The "standard" methods should be low hanging fruit for PlanetMath.

> *"Some people are more social in their problem solving than others – and some problems lend themselves better to social problem solving."* [C5]

## 7.3 A mathematician's perspective

*"It would be useful to have better systems for giving and receiving feedback."* [C6]

**Changing the nature of the space / Develop empirical studies and a critical apparatus** As Jamie explained to me, the relevance of changing communication technology, for a mathematician, can be discussed by analogy to considerations about a very different sort of technology: a commuter bicycle. A bicycle with a hybrid design and an internally-geared hub rides about 20% slower than a bicycle with true road geometry running a derailleur system. A communication technology can have similar beneficial or detrimental effects concerning knowledge transfer and synthesis. As this is the mathematician's bread and butter, it is a subject of some considerable concern. These concerns are not limited to computer mediated communication, however. A mathematician is sensitive to problems in exposition and direction – problems that are associated with an even more basic communication technology, language. In the seminar room, the audience asks questions both out of curiosity and to prompt the speaker. Over coffee, a non-expert may help to improve a research paper with a naive question. These are the kinds of interactions that designers of computer systems for mathematical communication need to consider. They are mostly missing from current systems, such the popular e-print repository ArXiv.org. * Jamie would like to being able to point out a problem in "*paragraph 7*" of a given text – or point to a completely different resource that does a better job.

*"Highly-abstracted and non-expository articles are hard to understand: they suffer from a kind of impenetrable quasiformality."* [C7]

**Changing what I know about myself / Find companions for the journey** We looked at the definitions of the mathematical term *ultrafilter* on PlanetMath and on Wikipedia (see Figure 11). In PlanetMath's definition, an ultrafilter is defined to be *filter* with certain properties. Wikipedia's definition describes the object first in terms of basic features of sets. It then develops several different equivalent conditions, and finally gives a definition in terms of filters. The PlanetMath definition takes up roughly the same amount of space as Wikipedia's "preliminaries", and manages to squeeze in a terse treatment of "types of ultrafilters." However, after the preliminaries, the Wikipedia article goes on to deal with *completeness*, *generalization to partial orders*, *types and existence of ultrafilters*, *applications*, *ordering on ultrafilters*, and *ultrafilters on* $\omega$. It also provides some interesting-looking references, for instance, to a paper on "Arrow's Theorem and Turing Computability". In short, the Wikipedia definition appears to be superior to the PlanetMath definition in all the relevant ways: it is relatively intuitive, complete, and

*HTTP://ARXIV.ORG/

A COLLECTION $\mathcal{U}$ of SUBSETS of $X$ is an *ultrafilter* if $\mathcal{U}$ is a FILTER, and whenever $A \subseteq X$ then either $A \in \mathcal{U}$ or $X \setminus A \in \mathcal{U}$. Equivalently, an ultrafilter on $X$ is a MAXIMAL filter on $X$. More generally, an ULTRAFILTER OF A LATTICE is a maximal proper filter of the lattice. This is indeed a generalization, as an ultrafilter on $X$ can then be defined as an ultrafilter of the power set $\mathbb{P}(X)$.

**Types of ultrafilter** For any $x \in X$ the set $\{A \subseteq X \mid x \in A\}$ is an ultrafilter on $X$. An ultrafilter formed in this way is called a *fixed ultrafilter*, or a *principal ultrafilter*, or a *trivial ultrafilter*. Any other ultrafilter on $X$ is called a *free ultrafilter*, or a *non-principal ultrafilter*. An ultrafilter on a finite set is necessarily fixed. On any infinite set there are free ultrafilters (IN GREAT ABUNDANCE), but their existence depends on the Axiom of Choice, and so none can be explicitly constructed.

An ultrafilter $\mathcal{U}$ on $X$ is called a *uniform ultrafilter* if every member of $\mathcal{U}$ has the same cardinality. (An ultrafilter on a singleton is uniform, but this is a degenerate case and is often excluded. All other uniform ultrafilters are free.)

HTTP://PLANETMATH.ORG/ULTRAFILTER

Given a set $X$, an ultrafilter on $X$ is a set $U$ consisting of subsets of $X$ such that

1. The empty set is not an element of $U$.
2. If $A$ and $B$ are subsets of $X$, $A$ is a subset of $B$, and $A$ is an element of $U$, then $B$ is also an element of $U$.
3. If $A$ and $B$ are elements of $U$, then so is the INTERSECTION of $A$ and $B$.
4. If $A$ is a subset of $X$, then either $A$ or $X \setminus A$ is an element of $U$. (Note: axioms 1 and 3 imply that $A$ and $X \setminus A$ cannot *both* be elements of $U$.)

A characterization is given by the following theorem. A FILTER $U$ on a set $X$ is an ultrafilter if any of the following conditions are true:

1. There is no filter $F$ finer than $U$, i.e., $U \subseteq F$ implies $U = F$.
2. $A \cup B \in U$ implies $A \in U$ or $B \in U$.
3. $\forall A \subseteq X$: $A \in U$ or $X \setminus A \in U$.

HTTP://EN.WIKIPEDIA.ORG/WIKI/ULTRAFILTER

**Figure 11:** *Definitions of "ultrafilter", from PlanetMath and Wikipedia*

well-referenced. There could still be some specialized look-up purposes for which the PlanetMath is better – but one thing it does not provide is intuition. This is not to say that the PlanetMath article is "wrong." It may well be that after unwinding the recursive definitions, and expanding the attached articles, one could come to a clear and complete understanding of filters and ultrafilters.* A "*quasiformal*" style of writing is much more prevalent on PlanetMath, although it is not absent on Wikipedia. Wikipedia's "anyone can edit" policy tends to produce articles that are "good enough" on average (Krowne, 2005). It seems fairly likely that critical feedback about PlanetMath's ultrafilter article, of the kind described here, hasn't made it to the author(s) yet. However, the problems may more properly lie at the platform level. On PlanetMath, it is possible to create

*However, for technical reasons, attempting this wouldn't be so easy. The word *filter* in the PlanetMath definition was autolinked to the definition of the more specialized concept *lattice filter*, rather than the actual definition of a filter, putting the reader on a bit of a chase to find the relevant definitions.

an account, submit a correction, wait for the author to respond, and then check their response – but this workflow runs counter to the design principle that states "*with each click you require, you lose half your audience.*"* On Wikipedia, you could just make the change directly. Flaws in exposition point to the salutary (but missing) effect of contact and discussion with other people.

**Changing my perspective / Work with real users** An instructor who would like to make use of a peer pedagogy must deal with the resistance that students feel toward speaking with one another. It would be helpful to convince the students that there are benefits to the extra work and exposure to critique. Students could be convinced that they will need to practice social skills in order to improve their workplace-readiness. They could also be convinced that group work or peer review can improve the quality of their understanding and their final marks. It may be easy to demonstrate that interaction with others helps to avoid the more obvious unthinking mistakes. This might be done by assigning homework to be completed in, or discussed by, small groups. This model stands in contrast with the more fully disaggregated model used in online Q&A systems. Incentives in the disaggregated model tend to produce Zipf-like distributions: in an instructional context, it's important that the greater portion of any "long tail" pass above a minimum threshold of quality. Jamie has previously tried using a standard Q&A system for course support. The small-group model asks for a different set of social skills.

> *"Students are not comfortable sharing their work with other students. They are only somewhat comfortable showing it to their professor, whom they regard as one might a medical doctor."* [C8]

**Changing content or connectivity / Study and build nonlinear interfaces** It may take months or years to get a given model "*loaded into your head*," but once you do, you can then see how manipulating it in one way "*over here*" will produce a change "*over there*." First and foremost, a mathematician looks for tools that will help them build effective mental models. This often means creating useful high-level abstractions. This is different from quasiformality, since the aim is to provide an intuitive, sharable, handle on a topic. For example, a picture is an abstraction that can help a reader to instantly grasp the notion of a Cauchy sequence. If some formalism is used, something very light-weight – e.g. the structured proofs of Lamport (1995) – is preferable to something heavy – e.g. Hales's (2006) Flyspeck.† Parallel points apply to user interface design. As already mentioned, being able to edit a Wikipedia page without logging in is seen as an asset; being able

> *"Formalisms are only useful when the model can't be held in your head."* [C9]

*John McLear, personal communication.

†HTTP://CODE.GOOGLE.COM/P/FLYSPECK/

to quickly click "Was this post useful to you?" helps create a digital trace that might be re-used in various ways; and even a dynamic layout on a web page tends to look "*more professional*" than a fixed-width layout. Related points apply to the technological accouterments of peer pedagogies. Students will not be interested in procedures, like using a course wiki or course forum that do not provide a clear and tangible benefit. Jamie, and others at his institution, seem to agree that the essential skill is "*thinking carefully and critically*" [§4.2, p. 49].

*"Wikipedia seems to have better coverage, better exposition, and a nicer-looking interface."* [C10]

**Changing objectives / Limit philosophizing** Of the three implied goals, "quality of exposition" seems like the hardest one to deal with, as it may require rethinking the entire way in which editing and feedback works on PlanetMath. But implementing a *standard* for quality is perhaps not so complex. On Wikipedia, templates are used to indicate that an article "*needs attention from an expert*" or that it "*may not meet Wikipedia's general notability guideline*." We could implement a set of templates for quality in mathematics exposition, so it would be easy to make it clear that a given article "*needs an example*," or "*needs a more intuitive presentation*." Even if without allowing edits from non-logged in users, it would be relatively straightforward set things up so that users could tag articles using a constrained vocabulary.

## 7.4 A reflective perspective

*"Empirical studies of mathematical discourse are a key research focus."* [C11]

**Changing the nature of the space / Develop empirical studies and a critical apparatus** In Alison's research for her PhD (Pease, 2007), she implemented Lakatos's theory of "*informal, quasi-empirical*" mathematics that grows "*through the incessant improvement of guesses by speculation and criticism*" (Lakatos, 1976) in a collection of intelligent computational agents, testing and extending the approach. She also finds significant value in computer mediated communication between humans. Transcripts of contemporary mathematical exchanges provide a more detailed picture of what happens when people do mathematics together than what is found in Lakatos's dialogues, or historical records of mathematical exchanges in old letters. As she put it, this is as close as she can get to having access to mathematician's brains. In "Seventy Four Minutes of Mathematics" (Pease & Martin, 2012), user comments are coded as *concepts*, *examples*, *conjectures*, *statements related to proof*, and "*other*" (an apparatus inherited from Lakatos): Table 14 reproduces the exemplars with which these categories are introduced in this paper. In "informal logic," the focus is usually on proof, but other broad topics of interest for Alison are listed in Table

**CONCEPTS** - "*Since the points are in general position you could define the* ***wheel*** *of* $p$*,* $w(p)$*, to be a radial sequence of all the other points* $q \neq p$ *around* $p$*.*"

**EXAMPLES** - "*If the points form a convex polygon, it is easy.*"

**CONJECTURES** - "*Is it possible to prove that any point and any line will do?*"

**PROOF** - "*Maybe the strategy should be to take out the convex hull of S from consideration; follow it up by induction on removing successive convex hulls.*"

**OTHER** - linking one thread to another, certifying the proof as complete, etc.

**Table 14:** *"Concepts, examples, conjectures, proof, and other" - five categories used by Alison Pease and Ursula Martin in "Seventy four minutes of mathematics: An analysis of the third Mini-Polymath project"*

**EXPLANATION** - "*This seems to be right, but there something I don't understand. Please see if you can help me with it*[.]" [...] "*If I understand well your example: the problem is that you must give an orientation to the line. Then, left and right are define with respect to this orientation*[.]" [...] "*Got it! Kind of like a turn number in topology. Thanks!*" (Pease & Martin, 2012)

**UNDERSTANDING** - But how does understanding relate to explanation? E.g. often explaining something in greater detail will confuse the listener.

**MOTIVATION** - Which can be considered in a sociological sense; for example when and where are people motivated by "addictions"?

**LINGUISTICS** - Including linguistic moves that help to build community, like talking about "*our*" instead of "*my*", etc.

**Table 15:** *"Explanation, understanding, motivation, and linguistics" - topics of interest in Alison's research*

15. This work is focused on studying what takes place in existing systems rather than on system design. However, platforms that more explicitly represent the kinds of things Alison and her collaborators find in the content would make certain aspects of her job easier; *cf.* (Martin & Pease, 2012).* Lange (2007) describes work on a semantic wiki, and Lange, Bojārs, Groza, Breslin, and Handschuh (2008), an ontology for argumentation that could likely be adapted for this purpose.

*Although they are not system building in the software sense, note the phatic, channel-creating, role of the "linguistic" moves mentioned in Table 15; *cf.* (Elyachar, 2010).

**Changing what I know about myself / Find companions for the journey** Data from PlanetMath could be coded at the text level or at the hypertext level, and modeled as a forest of interconnected concepts, examples, conjectures, and proof steps. At the hypertext level, the grammatical moves described in Table 10 [§5.2, p. 74] could be given "senses" associated with the categories listed in Table 14, for instance:

*"How does experience build towards understanding?"* [C12]

$$A \xleftarrow{\text{omits concept}} C, \quad X \xleftarrow{\text{for example}} T, \quad A \xleftarrow{\text{suggests that}} P, \quad P \xleftarrow{\text{partially solved}} S_0$$

If PlanetMath hosts interactions that are of interest to researchers, this would be a good sign that it is doing something that is in a certain sense new – even if this is achieved by simulating the features of older models. Anything researchers are able to learn about the way mathematical discourse works can inform future work on the system, and help to boost the relevance for typical end users.

**Changing my perspective / Work with real users** An example from one of Alison's earlier studies was the term *landmine*, introduced in a combinatorial problem solving context. This term almost begs to be made into a neologism once again, to describe the knock-on effect of a given new usage. We could measure the impact of a given post (or term) by measuring the number of follow-up posts (or uses). Similar features are modeled in the Behavior Ontology described in Angeletou et al. (2011), using the property `oubo:PostImpact`. This metric could be used to promote important posts to a place where newcomers would easily spot them. A focus on terms means that a forum conversation can be straightforwardly modeled as a graph that is covered by the trees which form its threads.* Graph theoretic techniques could be applied to compute and show the *centrality* of a given person, post, term; or example, conjecture, *etc.*, if this has been formally coded.

*"It would be useful to be able to detect the first use of a word within a given episode of discourse, and to measure it's impact."* [C13]

**Changing content or connectivity / Study and build nonlinear interfaces** As discussed above, quasiformality can be difficult for a reader who often relies on informal or non-mathematical language, or pictures, to gain a sense of understanding. One concrete application of network structures within the PlanetMath encyclopedia would be to show the distance of the terms used in a given exposition from a set of basic definitions which are taken as axioms. This would essentially be a topographical map, and gradients and

*"Can we build more detailed models of mathematical discourse?"* [C14]

* *Cf.* Eco [§4.5, p. 61].

flows could be computed. Such a model could help explain the subjective experience of expository quality in terms of linguistic features (e.g. anaphora) and cognitive models (e.g. cognitive load). With this as a basis, we could then take further steps to explore how knowledge grows and spreads. A graphical approach could be used by research mathematicians to help manage posts and metadata. The user could browse through topics as bubbles, "*open them up*" to zoom in on details of interest, "*attach*" a notebook to a given topic at a given point, or "*connect*" topics with additional comments. This would give a graphical interpretation to maneuvers that currently take place in textual and hypertextual form. A promising related development in the cartography of mathematics is described by Dörrie and Kohlhase (2013), following earlier work by Dave Rusin.*

**Changing objectives / Limit philosophizing**

*"Even if computer mathematics did a good job of simulating human mathematics, it won't do things the same way humans do."* [C15]

For comparison, even though there are computers that are very good at chess, they generally do not play like humans. Timothy Gowers and Mohan Ganesalingam (2012) have been working to teaching a computer how to do "*routine mathematical problems*" – that is, problems where "*the obvious thing works*." This, and most other research in computer mathematics, is more or less distinct from research on informal logic. Typical theories of argumentation also focus on proof and truth (Pease & Aberdein, 2011), leaving issues associated with expository quality and collaboration to one side.† Appendix B reworks two examples presented by Gowers and Ganesalingam, aiming to illustrate how social theories focused on learning and collaboration might be applied to solve standard mathematics problems. PlanetMath may be able to offer a hybrid digital/analog tutoring system long before a comparable fully computerized system exists that can perform at the same level. Indeed, in contrast to computer chess, it is possible that the relevant target for computer mathematics is not "human mathematics" at all, but social mathematics. "*We may compare a man in the process of computing a real number to a machine*" (Turing, 1936) – but "*the program is best conceived of as a little trial court, or as an evidence-collecting and evidence-weighing procedure*" (Minsky, 1967).

> [W]*hen we write a large program, with many such courts, each capable if necessary of calling upon others for help, it becomes meaningless to think of the program as a "sequence."* [...] [O]*nce past the beginner level, programmers* [...] *write for the individuals of little societies or processes. For try as we may, we rarely can fully envision, in advance, all the details of their interactions. For that, after all, is why we need computers.* (Minsky, 1967)

*HTTP://WWW.MATH-ATLAS.ORG/

†Walton's agential theory of "critical questions" (Walton & Godden, 2005; Walton, Reed, & Macagno, 2008), while still focused on truth claims, is closer than earlier theories, like Toulmin's (1958).

## 7.5 Summary

Table 16 summarizes the findings from qualitative fieldwork with potential users and stakeholders. It illustrates how the paragogy framework can be used to draw out interesting and relevant design themes.

These findings can be applied directly to guide the implementation work described in Chapter 8. Given the ambitious nature of some of the points that were raised, it is likely that the issues discussed here will inform the development of PlanetMath/Planetary for time to come.

This chapter incorporates views from three important categories of potential users: students, mathematicians, and researchers who study mathematical practice. Chapter 10 will return to these findings again to compare them with the views of users of the realized system.

| Student | Mathematician | Philosopher |
|---|---|---|
| α. | β. | γ. |
| "Trust" and "credit" are two important and potentially related issues for users/contributors. | We need an efficient system for integrating user ideas and comments. | Researchers can study the content or the system in almost interchangeable ways. |
| δ. | ε. | ζ. |
| Progressive problem solving and incremental feedback are important for users, particularly new users who are building their identity as an effective problem solver. | Discussion and critique have a salutary effect; deficiencies in exposition may be a result of their absence. | We should be able to build research-ready data flows as long as the system is actually used. |
| η. | θ. | ι. |
| People have instrumental, transactional, information needs and noninstrumental, interactional, learning needs. | People need to learn and practice social skills through interaction. | Graph theoretic methods can be used wherever we have explicit semantics or even simple models of terminology use. |
| κ. | λ. | μ. |
| Users and potential users have a lot to say about systems: how can we empower them to actually make changes? | Users want to be able to make adaptations that leave traces, and simple customizations that don't. | Visualizations of graphical knowledge structures could be used directly in the UI. |
| ν. | ξ. | ο. |
| Social problem solving is suited to some tasks more than others. | Coverage is good to work on, but quality of exposition is harder. | Computer understanding and formal theories of quality and effective social heuristics are good long-term goals. |

**Table 16:** *Overview of desiderata gathered using the paragogy framework*

# Part 4
# Results and discussion

# 8 Implementation

**PlanetMath's software system is rebuilt along the lines specified by the paragogy model, augmenting the collaborative authoring environment with tools for peer supported problem solving.**

## 8.1 The Planetary system

In 2010, in parallel to the exploratory research described in earlier chapters, the Planetary project launched. One of the project's key milestones was to rebuild and modernize PlanetMath's software. The project also aimed to create a software system that could be deployed and used in settings unconnected with PlanetMath. In order to facilitate this, Planetary uses the popular content management system, Drupal, as its basis, and connects Drupal with other open source components. The primary participants in this project were Michael Kohlhase of Jacobs University, Bremen, several of Kohlhase's students, and the current author.*

With regard to the system's deployment on PlanetMath, the main objectives were to be feature-complete relative to Noösphere, and to add new features relevant for learning mathematics. These new features include the introduction of problem and solution data types, collections for assembling content into interactive structures, along with other user-visible changes like a new syntax-highlighting source code editor and fast in-browser rendering, and new semantic models in the backend.

My role in the project was to lead the development and deployment of the version of the system needed for the PlanetMath use case. This involved integrating contributions

*HTTP://TRAC.MATHWEB.ORG/PLANETARY/WIKI/PEOPLE

| | **Basic** | **Enhanced** |
|---|---|---|
| *Interaction* | Drupal, ACE2/ShareJS editor | +JOBAD |
| *Storage, Access* | Drupal, Virtuoso | +TNTBase, Git |
| *Representation* | XHTML+RDFa | +OMDoc |
| *Processing* | LaTeXML, NNexus, PyRDFa | +JOMDoc, Krextor |
| *Content* | LaTeX (*e.g.* PlanetMath, ArXiv) | +sTeX |

**Table 17:** *Components of the Planetary system*

from other members of the team where relevant. A schematic of the system architecture is presented in Table 17, adapted from the earliest system paper describing Planetary (David, Ginev, Kohlhase, & Corneli, 2010).

Further enhancements to the system are being explored in deployments at Jacobs (David, Kohlhase, et al., 2010; Iancu, Jucovschi, Kohlhase, & Wiesing, 2014), integrating earlier work by members of the KWARC research group on knowledge management tools including Krextor (Lange, 2009), TNTBase (Zholudev & Kohlhase, 2009), OMDoc (Kohlhase, 2001), sTeX (Kohlhase, 2006), and JOBAD (Kohlhase, Giceva, Lange, & Zholudev, 2009). In 2011, an early prototype of the system was selected as a finalist in Elsevier's Executable Paper Challenge (Kohlhase et al., 2011). The system is currently in active use, not only as a web portal on PlanetMath, but also as a course management tool for Kohlhase's introductory computer science courses, and on the new "flexiformal" (Kohlhase, 2012b) mathematics website, MathHub.info.*

PlanetMath/Planetary moves in the directions indicated by the survey presented in Chapter 7, and Drupal's extensibility opens the door to further improvement. For example, the use case sketched in Figure 3 [§2.3, p. 31] has been brought considerably closer at the level of knowledge representation, but the system currently lacks the reasoning support that would be needed to finish the job. I collaborated concurrently on another project that added a recommender service to Drupal (Mulholland, Wolff, Zdrahal, Li, & Corneli, 2013), and integration of the corresponding features into Planetary appears to be simply a matter of time.

What is most essential for current purposes is that Planetary can be discussed, studied, and developed further together with PlanetMath users. The renewed attention to system development restores an empirical aspect to PlanetMath: more than "*kit*" for doing math-on-the-web, PlanetMath/Planetary is a "*research device*" for studying mathematics as a cultural system; *cf.* (Rheinberger, 1997, p. 81). This research programme is developed further in Chapter 9, but the system itself constitutes an important research result, and not just a means to an end. PlanetMath/Planetary is the most concrete synthesis of the ideas that have progressively developed in the course of this work.

*http://mathhub.info

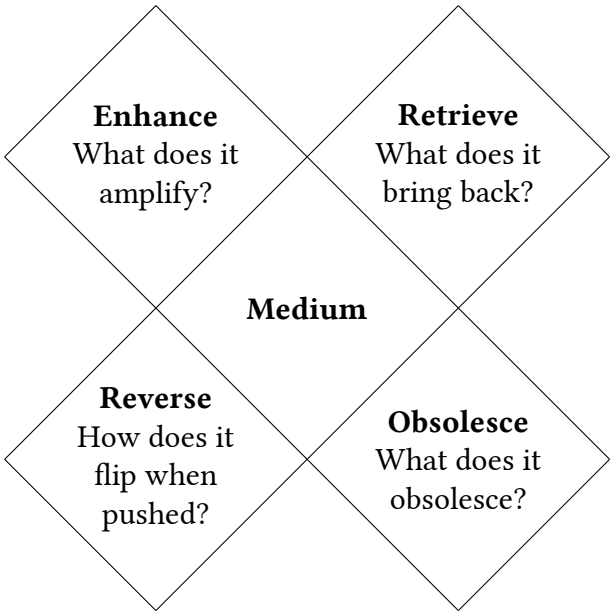

**Figure 12:** *Marshall McLuhan's tetrad of media effects*

It is a functional actor-oriented model of the way people do mathematics – although it is, of course, only a partial model. The paragogy framework is used below as an organizational device [§3.3, p. 41] to describe the system's high-level specification.

1. **PlanetMath/Planetary should be a special-purpose tool that is customized to suit the challenges of learning mathematics.**
2. **Learning mathematics is an active process that is centered on problem solving; to get the added benefits of peer support, participants have to interact with one another.**
3. **Users will contribute problems and solutions; discussions about problems should spur new engagement among encyclopedia editors and teachers.**
4. **To be viable, the system should facilitate mathematical meaning making; the foundations for this include emergent structure, pragmatic knowledge building, ongoing redesign and evolution at the system level, and the development of new content-focused subcommunities.**
5. **The system should support increasingly refined user and domain modeling, in order to become an increasingly high-fidelity actor-oriented model of mathematical behavior.**

The next section expands these points based on consultations with PlanetMath users and new stakeholders, as described in Chapter 7. After describing the implementation strategy, the following sections present Planetary's new features and analyze them using Marshall McLuhan's (1989) tetrad of media effects (Figure 12).

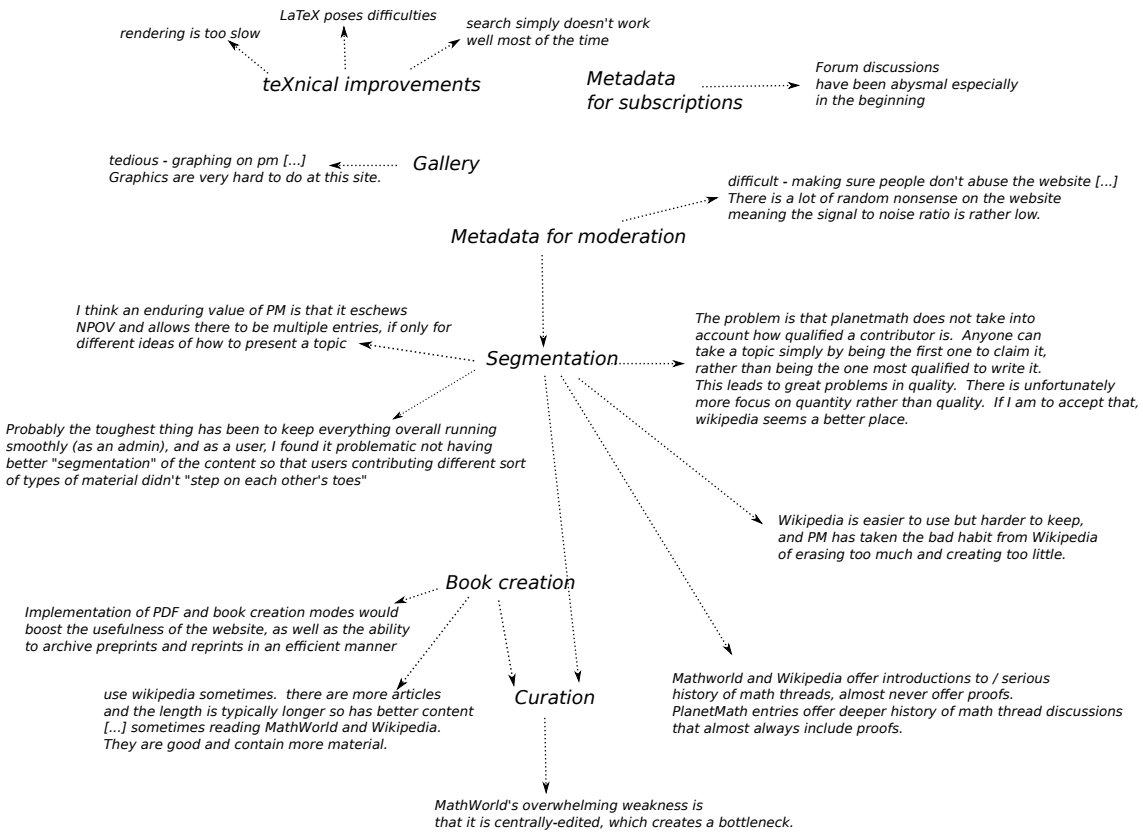

**Figure 13:** *Participatory design: surveying users of the legacy system*

## 8.2 Fleshing out the specification

### Participatory design

On December 16, 2011, a questionnaire was circulated by email to 30 of PlanetMath's historical top contributors, inviting feedback on an early "alpha" version of the new website as a work-in-progress, which had been deployed on alpha.planetmath.org. The questions aimed to discover the mathematical goals and interests of top contributors, as well as their sentiments about PlanetMath and other related websites, like Wikipedia. Feedback was provided by 10 respondents, and this is summarized in Figure 13. Several central themes are summarized below.

**Geometric and visual thinking** The frustration people experienced working with images on PlanetMath/Noösphere underscores the importance of visual, analog, thinking for making meaning in mathematics. Improved support for creating and sharing images could only help – particularly for learners who are using the site to build intuition, not just to check the details of a definition.

→ Better support for mathematical diagrams is one feature of Dimension 1 of the specification: the mathematical symbol system includes both analog and digital features.

**Different levels of qualification** If one were to concede the point that Wikipedia's encyclopedia is a better reference resource – which is convincing enough to be considered – that still leaves the question of a place for everyone who is not yet an expert to engage. In mathematics, these people are often students, and their traditional mode of becoming more mathematically qualified is to solve problems.

→ Adding problem solving support to cater to non-expert users is the essential feature of Dimension 2.

**Breadth, Depth, and Quality** In-depth treatments of individual topics and broad coverage of many different topics are both considered valuable. Breadth and depth are subject to social and technical constraints, including availability and incentives for experts, and suitable tools for dealing with complex presentations. High-quality exposition and structured presentations are important for anyone learning mathematics. Some people doubt whether a "crowd" can build things like. Better support for making and critiquing books, problem sets would certainly help, along with techniques for semantic modeling that can assist in quality control.

→ One of the key ideas behind Dimension 3 is that feedback from students and careful attention to their needs will help editors find places where exposition could be improved.

**Moderation difficulties** Related to the point just mentioned, there is tension between having something online *per se* (which people often like, since it potentially helps them gain exposure, get feedback, and find potential collaborators) – and having something in the encyclopedia, where others end up having to interact with it. For example, my own uploads from APM-Ξ didn't fit well in PlanetMath's encyclopedia, but I would have liked to find some place for them on PlanetMath (Chapter 2).

→ Suitable strategies for segmentation would help with many of the sub-points of Dimension 4.

**PlanetMath's unique model** The ownership model blends "Wikipedia" and "Scholarpedia"* approaches. Raymondite homesteading is part of this model, and the intent is that this will give experts the chance to manage their own content. However, this comes with some of potential quality control issues: what if instead of improving an article, an owner only "squats it"? In fact, users who don't respond to corrections must orphan their articles – but the ownership model still slows down change relative to Wikipedia. An improved co-authoring workflow could take care of some basic points of conflict. In

*HTTP://WWW.SCHOLARPEDIA.ORG

addition to ongoing discussions with users, better data gathering and analysis should help detect places where users are running into difficulty.

→ Understanding and better serving user needs is one of the key applications of Dimension 5.

## Connections to stakeholder desiderata

Table 18 further expands the specification by referring it to the desiderata identified in preliminary field work (as summarized in Table 16 [§7.5, p. 104]). This yields a detailed outline of work for the implementation project.

This expanded view shows how the five focal dimensions of change at the system level are, here, projections of a more complicated change process. Rather than "dimensions" it may be more accurate to speak of them now as "subspaces," or "subprocesses," with the further caveat that these are not wholly distinct, but that they will interact with one another. Each of the five subspaces traces a virtual engagement between the dramatis personae Student, Mathematician, and Philosopher, in the (changing) context of the system-under-development. All of these figures are themselves involved in their own processes of change [§3.3, p. 41]. When compared with Chapter 7, what's new here is that it is now seen how these change processes can be related to each other.

The descriptions presented in Table 18 were not obtained by reading across the rows of Table 16, but by refactoring its elements to tell a more coherent story. For example, along Dimension 3, through the hinge-pin of *motivating users to contribute problems and discuss solutions*, trust and credit ($\alpha$) are now seen as connected with discussion and critique ($\varepsilon$) as well as data-driven research looking at topics like the way understanding develops in dialog ($\zeta$). As the nature of the student's environment changes so that he or she can get credit for participating in activities online, the mathematician and philosopher must increasingly understand their roles to be connected to discourse. The system, correspondingly, should adapt to support participation at varying levels of familiarity and literacy, not only with regard to mathematical concepts and proof techniques, but also the relevant forms of social engagement.

This broad programme still only points in a general way to what needs to be implemented, rather than to a manifest of specific implementation tasks. Geertz notes that the separateness of plans of this type from actual cultural practice "*makes them less useful as models for the interaction of cultural patterns*" (Geertz, 1973, p. 250). On analogy with Vygotsky's view that "*the primitive child is a healthy child*" (Vygotski, 1929), the implementation approach will focus on the minimum kernel of features that is needed to build a concrete working model, rather than an abstract picture. Interacting with a realized system will render the subsequent discussions and critique comparatively concrete.

**Dimension 1 (Desiderata η, λ, μ): "A special-purpose tool customized to suit the challenges of learning mathematics."** The system must deal with both informational and interactional needs of users. It should allow users to make learning-relevant adaptations and customizations. It should help people visualize and interact with mathematical knowledge – diagrammatic thinking is one basic aspect of this.

**Dimension 2 (Desiderata δ, θ, ο): "An active and interactive process centered on problem solving."** This should include features of progressive problem solving and incremental feedback, as well as the opportunity to learn and practice collaboration skills. We should build better models of expository quality and effective problem solving heuristics, and the relationship between them. As students become better at solving problems, they become more mathematically qualified: ideally, the system should be useful wherever the user is in their mathematical literacy lifecycle.

**Dimension 3 (Desiderata α, ε, ζ): "Motivate users to contribute problems and discuss solutions."** In order to accomplish this, we will have to address the issues of *trust* and *credit*. If we want to motivate new levels of engagement from editors and teachers, we will have to highlight the efficacy of discussion and critique. We should identify the meta-mathematical research problems associated with discourse in the space, and help researchers work on these problems. Following Timothy Gowers, let's ask: "Is massively collaborative mathematics instruction possible?"

**Dimension 4 (Desiderata β, γ, κ): "Support mathematical meaning making within the system and through ongoing system development."** Will user comments be heard and acted upon (whether at the level of "system" or "content")? Can users themselves contribute to development? Can we develop a rigorous approach to system change and development? One concrete problem is the tension between making it easy for contributors to add material, and making the things the reader sees high-quality. This invites an innovative approach to segmenting the site.

**Dimension 5 (Desiderata ι, ν, ξ): "Support user and domain modeling."** Can we discriminate between the tasks where social problem solving works better than individual effort, and vice versa? Can we understand the behavioral and semantic features of high-quality exposition? How can we facilitate graph theoretic analyses of questions like these? How can we understand the impact of system features (like the ownership model) on the user experience?

**Table 18:** *Design dimensions*

## 8.3 Implementation strategy

Figure 14 connects the specification described in the previous section to concrete system features. As can be seen by comparing with Figure 13, many long-standing feature requests have been addressed in the process of this conversion as well.

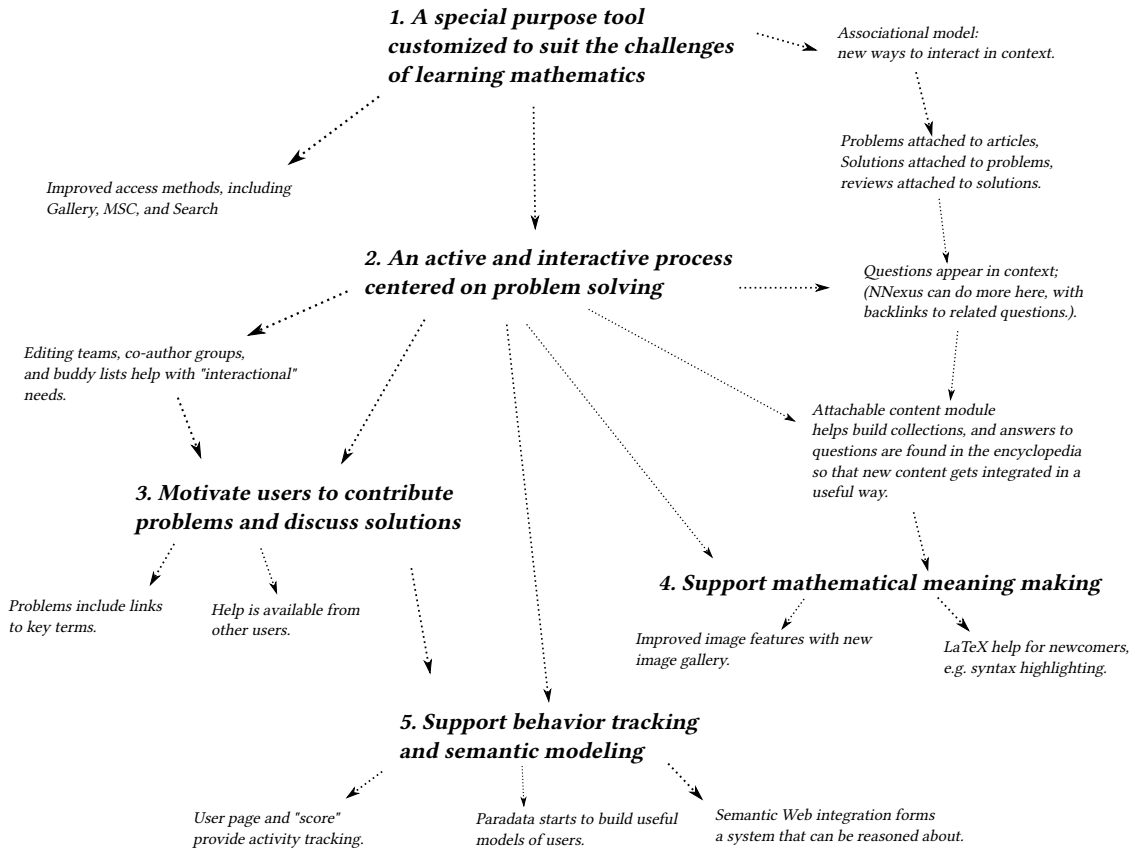

**Figure 14:** *Connecting the design specification to concrete system features.*

In order to realize this design and develop a solid foundation for further work, development began by rebuilding the main features of Noösphere from the ground up – using the extensible content management system (CMS), Drupal 7.* This allowed us to modernize and modularize the system in the process of building our enhancements. It cannot be emphasized enough how much an easy to install system built as customizations to a mainstream CMS helps with extensibility when compared with a difficult to install custom codebase.† This is important in light of the fact that we could not realistically do everything that everyone would have like to see done in the time available. An extensible modern system that combines feature-parity with Noösphere and new problem solving features was sufficient for current purposes. Not only is the system immediately usable

*HTTP://DRUPAL.ORG/DRUPAL-7.0

†Full installation instructions for Planetary are available on Github: HTTPS://GITHUB.COM/KWARC/PLANETARY/WIKI/INSTALLATION-INSTRUCTIONS

– featuring some noticeable improvements over Noösphere – it also allowed collaborating developers to build new working prototypes that open up interesting directions for further work. Development took place on Github to facilitate distributed revision, and developers made use of the integrated issue tracker.

In addition to Drupal, two other core components come together to form the new Planetary system. These are: (1) LaTeXML,* which we used to provide a modern, fast rendering system that supports semantic markup; and (2) the Virtuoso triple store,† which allowed us to begin to make use of semantic markup in a computational manner.

When compared with Noösphere, Planetary is better able to expose semantics at the fine-grained textual and bulky hypertextual levels. This means that in the future, much more information will be available for analysis along the lines indicated in Chapter 6.

As is the nature of open source collaboration, Planetary builds on a considerable body of prior work; *cf.* (Kohlhase et al., 2011). PlanetMath is the first major public demo of the Planetary platform. After a short overview of the system as a whole, this chapter will focus on *problem solving support* (problems, solutions, reviews, collections, questions), *data management* (personalized tracking, SPARQL integration via Virtuoso and PyRDFa), and *support for groups*, which I've been primarily responsible for developing in order to build PlanetMath/Planetary. Details on other features of the Planetary system – including real-time collaborative editing, Javascript-based interaction for readers, mathematics-aware search, and expressive semantic markup via sTeX – can be found in papers by other members of the Planetary team (Jucovschi, 2012; Kohlhase, 2012a; Kohlhase et al., 2009; Kohlhase, Matican, & Prodescu, 2012; Kohlhase, 2006, 2008).

## Overview of Planetary's features

After a first round of prototyping with Vanilla Forums‡ (Kohlhase et al., 2011), we settled on using Drupal 7 as the basis for the system. Drupal is a popular open source content management system, known for its modular approach. Many contributed free/open source modules are available, and the Drupal developer community offers a range of professional services. For processing mathematical text, we used LaTeXML, a parser that takes in LaTeX source code and generates XML, and from that, HTML+MathML.§

> *MathML is a low-level specification for describing mathematics as a basis for machine to machine communication which provides a much needed foundation for the inclusion of mathematical expressions in Web pages.* – http://www.w3.org/Math/

*http://dlmf.nist.gov/LaTeXML/
†http://virtuoso.openlinksw.com/dataspace/dav/wiki/Main/
‡http://vanillaforums.org/
§http://dlmf.nist.gov/LaTeXML/

From the user perspective, a significant advantage of MathML is that it transfers and renders much faster than other alternatives. It is rendered natively by an increasing number of web browsers, and the Javascript-based MathJaX provides a fallback solution in browsers where native MathML rendering is not available. MathML also lays the foundation for interactive in-browser services (Kohlhase et al., 2009).

We were able to use several contributed Drupal modules with zero configuration to reproduce some of the old features from Noösphere. Examples include the contributed privatemsg and watcher modules. Other modules could be used with some minor customization (*e.g.* scorekeeping via userpoints) or integration via an API (*e.g.* groups support using the Organic Groups module, og). Some features naturally had to be custom-built, for example, a new corrections module, and the drutexml module, which communicates with LaTeXML running as a web service.

Constantin Jucovschi used the wysiwyg module to add a custom real-time collaborative editor, based on ShareJS.* He is extending the editor with "bots" that provide a range of in-editor services (Jucovschi, 2012). The only code remaining from the legacy PlanetMath codebase is the NNexus auto-linking module, which Deyan Ginev has refactored into object oriented Perl, and adapted to run as a web service along the lines of the LaTeXML web daemon, which he also maintains; *cf.* (Ginev & Corneli, 2014).†

*Problems* and *solutions* are the key new objects, along with *questions*, *collections*, and *groups*. Working with problems and solutions, and integrating them with expository material from the encyclopedia requires new workflow and metadata management features. Table 10 [§5.2, p. 74] summarized the main activities planned for the new system, and connected these activities with the five dimensions of paragogy. Figure 14 now provides a significantly expanded view of a paragogical design for mathematics learning.

Many of the new features are familiar from other wikis, online communities, or offline problem solving contexts. Collections do require a brief introduction. The available interactions are similar to those associated with YouTube playlists,‡ *i.e.* collections are designed to help users organize articles, problems, and other content. In the mathematics context, collections are useful for sharing reading lists, problem sets, and more complex curricular objects; *cf.* [§1.2, p. 6]. A similar feature was developed by Silvan Reinhold (2006) for the WikiTrails system, which was designed to augment a MediaWiki installation with navigational and learning pathways. Trails could be created in "*automatic, semi-automatic, as well as manual modes.*" Christoph Lange (2007) points out that the knowledge embedded in wiki pages is not used by the WikiTrails system. In the current prototype, the collections mechanism integrates information about user interactions and

*https://github.com/jucovschi/ShareJS
†https://github.com/dginev/nnexus
‡http://www.youtube.com/yt/playbook/playlists.html

the hypertextual context. Deeper semantic integration is left for future work.

In the following section, the system features that were presented in capsule form in Figure 14 are unpacked and explored with screenshots from the live system deployed on PlanetMath.

## 8.4 System walk-through

Figures 15–25 show some of the key features of the developed system. The pages can also be browsed on PlanetMath.* The screenshots and discussion are organized in terms of the five dimensions of the design described in Table 18.

The clusters of features associated with each of these dimensions is reviewed in terms of the McLuhan tetrad (Figure 12), which helps to focus on specific, localized changes, in contrast, for example, to the more global concerns addressed by Richardson and Domingos (2003) [§4.5, p. 61]. Some of the pragmatic features associated with building large knowledge bases are enhanced by the new features and where something can be said about this it will noted – but there are other cultural factors that are relevant to peer produced peer learning that McLuhan's formulation is better at capturing.

### 1. A special purpose tool customized to suit the challenges of learning mathematics

Figure 15 illustrates the first point where a user might encounter one of the key new features of the system. When browsing an article, a block containing links to attached problems appears, if the article has attached problems. If there are no attached problems, the reader is invited to add one. The figure illustrates additional interactions that are available to any logged-in reader, when browsing an encyclopedia article. The reader can add a correction, ask a question, or add the article to a collection. Both the text of the article and the "look and feel" are worth commenting on.

In the past, PlanetMath used a range of different rendering systems. The earliest of these was LaTeX2HTML,† a system that converts mathematical expressions into in-line images. The most recent system used by Noösphere was jsMath, the immediate predecessor to the more widely-adopted MathJaX. Javascript-based client-side rendering with these tools is considerably slower than native rendering of MathML within the browser, which is currently best supported by Firefox's C++-based Gecko engine. Native support for MathML is not present in all modern browsers, so Planetary includes MathJaX as a fallback option. LaTeX source code and rendered PDFs are also made available.

*Up-to-date screenshots, together with links to live pages on the system, are collected at HTTP://PLANETMATH.ORG/PLANETARYRELEASENOTES.

†HTTP://WWW.LATEX2HTML.ORG/

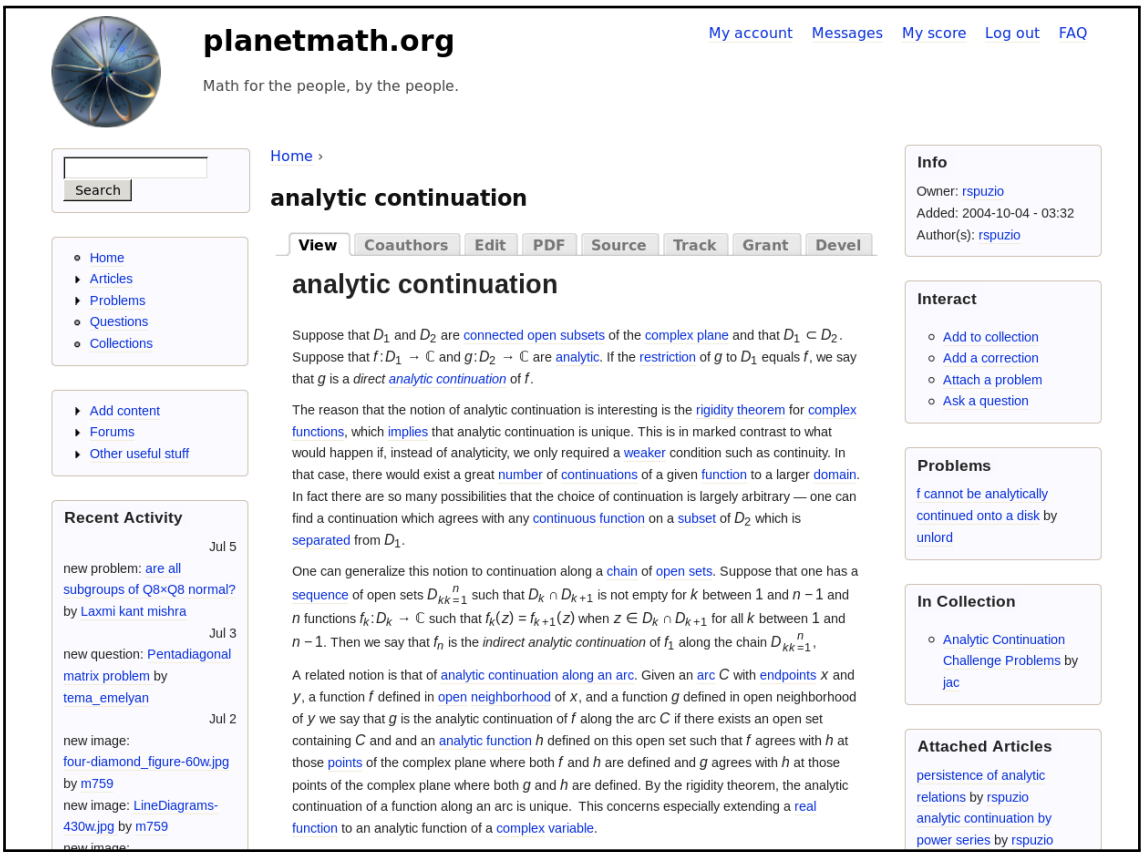

**Figure 15:** *"Article UI" (reader view), including problems attached to articles.*

The three-column theme was implemented by Alex Dumitru using Drupal's popular zen theming system (version 7.x-3.1).* The idea was to provide the basic interactions and site messages in a simple version of a "*heads-up display*".† One designer I spoke with was not greatly impressed, and said that the site has an "*early nineties look.*"‡ As noted in Chapter 7, a layout that used all of the space on the page for text might look "*more professional*" [§7.3, p. 99]. Some additional theming and Javascript work would enable us to make the sidebars stay hidden unless needed, but at the outset of the project there were other more pressing issues to solve.

The HTML produced by LaTeXML expresses mathematical symbols using their Unicode representations. Some of the "obscure" symbols (like Fraktur fonts) occupy registers beyond the Basic Multilingual Plane (0x0000 - 0xFFFF) supported by MySQL's UTF8 encoding. Planetary seems to be the first system to use LaTeXML together with a MySQL database. A resolution was reached by upgrading MySQL and converting to the richer UTF8MB4 encoding,§ and creating a (local) patch for Drupal's core database module.

‡Anna Keune, personal communication
§HTTP://DEV.MYSQL.COM/DOC/REFMAN/5.5/EN/CHARSET-UNICODE-UTF8MB4.HTML

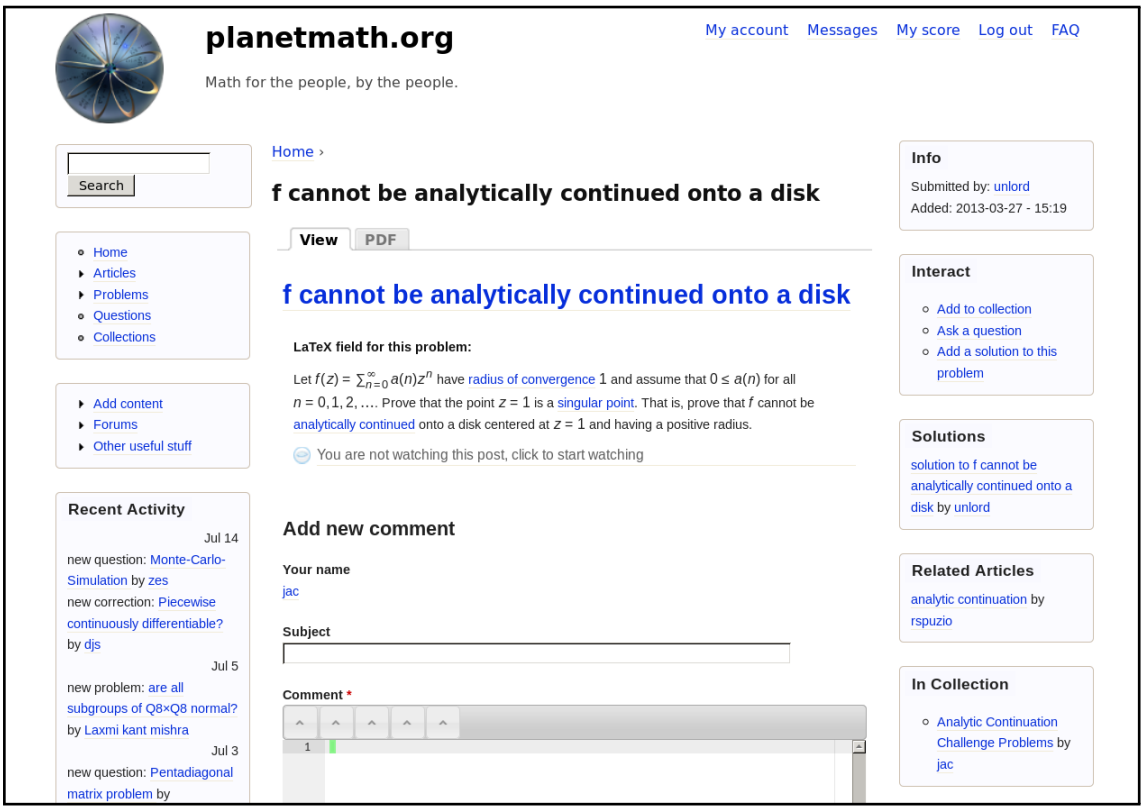

**Figure 16:** *Problems are attached to articles; solutions are attached to problems*

Figure 16 shows a problem, with its own set of interactions, including the ability to add a new solution. Once solutions have been added, they will be listed in another block. Problems also come with a "Related Articles" block that shows the articles to which the problem has been attached (if any). Some users might prefer *not* to know that solutions are available until they specifically ask for a hint; Drupal would make it easy to accommodate this sort of user preference.* In terms of our ability to control system features at this level, we can compare Planetary with WorkingWiki, a MediaWiki extension for interacting with source code of various forms (including LaTeX).† WorkingWiki is an excellent program that pushes the envelope of what can be done with wikis – and, like Planetary, it uses LaTeXML for rendering. The ease with which different kinds of content can be created and connected together in Drupal confirms that using a CMS is a good choice for the Planetary project. Interconnections between different kinds of content, and interactions around these connections are the essential features of the design (Figure 1 [§1.4, p. 12]). Using LaTeXML opens the door to interaction with individual pieces of content, via "deep links", since each element on the page is supplied with a unique identifier (`xml:id`).‡,§

*https://github.com/KWARC/planetary/issues/343

†http://www.mediawiki.org/wiki/Extension:WorkingWiki

§https://groups.google.com/forum/#!topic/planetary-dev/xP0PiSQVQNE

***Enhance*** The improvements described here target the relational features of the PlanetMath system. Not only are objects related to other objects in new ways, the text itself is enhanced, which facilitates new ways for people to interact with system contents. For instance, it is now possible to link to and discuss individual elements of the page. At both "micro" and "macro" level, the system has better support for user interactions.

***Obsolesce*** The first target of the Planetary project has been to obsolesce Noösphere by building a system with feature parity. A potential longer-term goal is to obsolesce other online or offline mathematics resources, by growing to include feature parity with more of them. At this stage, the key point is to support customizability and extensibility in Planetary system at all levels.

***Retrieve*** Reference material is now connected explicitly to a problem solving context. The sense of mathematics as a subject that is only learned actively is brought into focus in the new system.

***Reverse*** When the relations between different topics are developed further, it may be easier to conceptualize PlanetMath's content not simply as a textual or hypertextual corpus, but as a graphical image or interactive mathematical object. The MathMap project by Jan Wilken Dörrie at KWARC offers an early prototype for this experience, and currently provides an alternative access method to PlanetMath's content.*

## 2. An active and interactive process centered on problem solving

Figure 17 shows the new LaTeX editor in action, with the user in the process of adding a solution to the problem that was shown in Figure 16. The text of the problem statement has been automatically retrieved and copied onto the screen above the LaTeX field, so the user doesn't have to open multiple tabs to keep track of the basic information they need to solve the problem. This is achieved by using a custom *view mode* and a custom template for rendering the solution entry form. The new '`content`' view mode produces only the content of the problem, without the perpheral features that appear when the problem is rendered as a webpage.

By following the links to technical terms used in the problem (here, to PlanetMath's articles on "*radius of convergence*", "*analytic set*", and "*analytical continuation*"), the user can remind him or herself of the definitions. In the future, we could do much better, by generating a "course packet" on the fly to assist the problem solver. The latest version of NNexus embeds RDFa into links, which makes the connections between pages

*HTTP://MAP.MATHWEB.ORG/

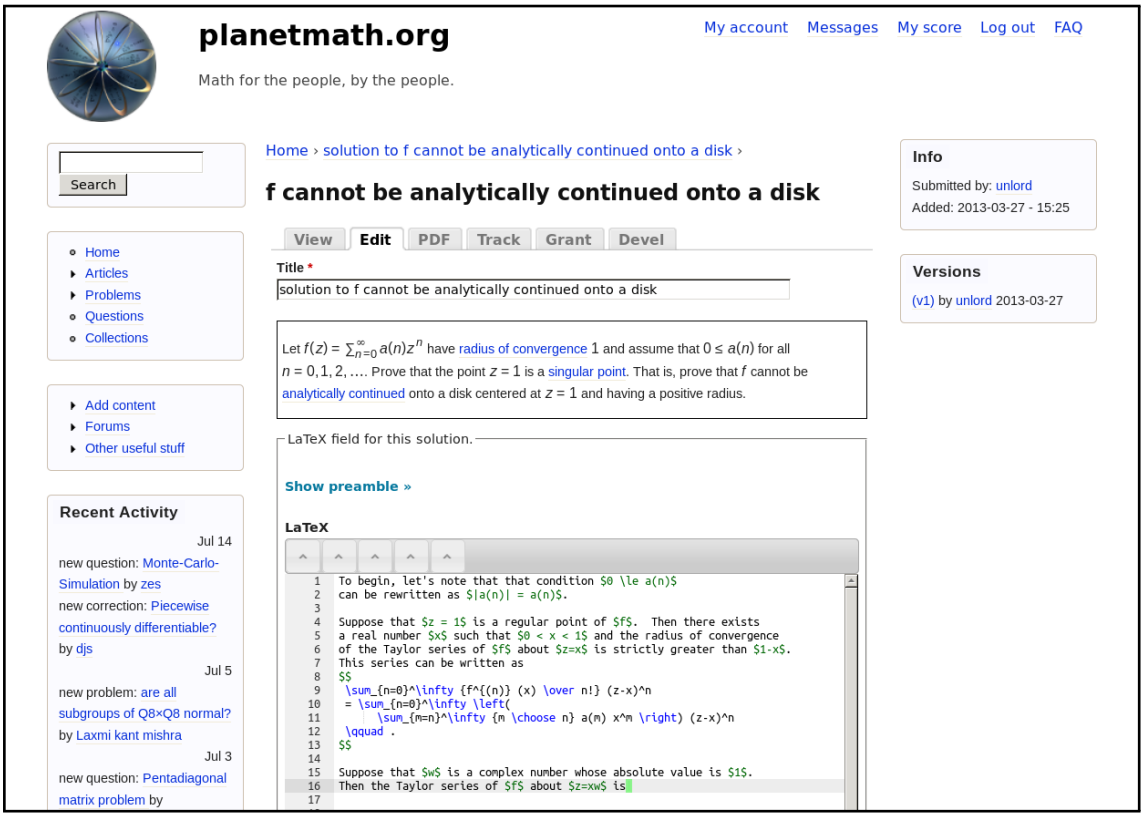

**Figure 17:** *Solving a problem*

explicit; the relevant information for building this sort of on-the-fly course packet is now available via a SPARQL query.* However, to deliver good results, it will be important to develop better strategies for NNexus to use to steer links accurately, since there are often different definitions for the same term: some of these strategies include steering based on the Mathematics Subject Classification, entropy-based approaches, and adding mechanisms for users to give feedback on mis-directed links.† Improving NNexus's accuracy is currently a work in progress (Ginev & Corneli, 2014). In the event that a problem is still too hard to solve, the user can ask a question via one of the interactions offered in Figure 16. This is in line with the example use case for combined peer learning and peer production workflows that was described in Figure 3 [§2.3, p. 31]. Links to easier (or harder) related problems would be useful to add, and with more metadata (for instance, the "mathematical depth" of the terms used in the problem [§6.4, p. 88]), these too would be a SPARQL query away.

Although automatically-created reading lists and problem sets are just beyond the Planetary system's current capabilities, we have stable support for building them manually, via the collections mechanism.

*https://github.com/KWARC/planetary/issues/323
†https://github.com/dginev/nnexus/issues/34

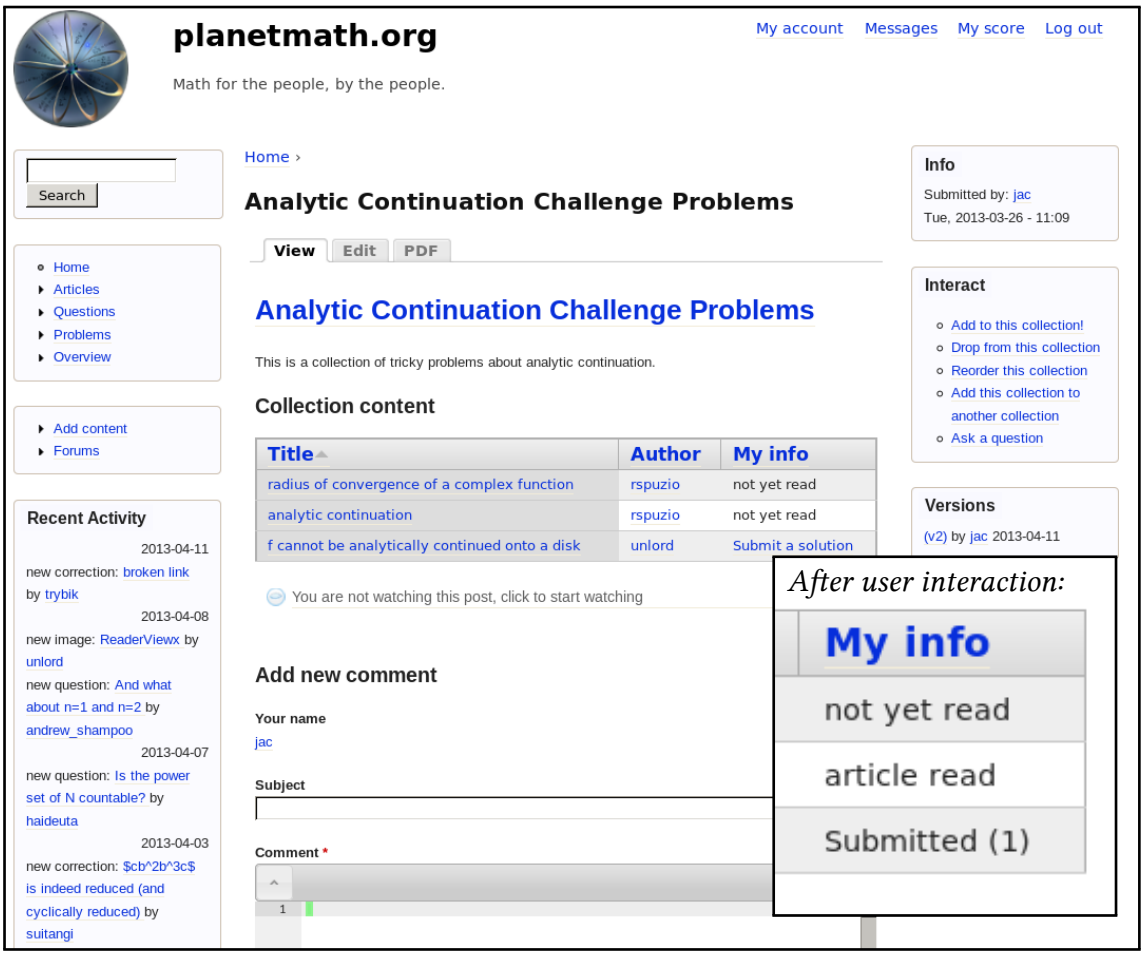

**Figure 18:** *Paradata that shows up as a user works their way through a collection*

Articles, problems, and other content can be added to collections, which function as "playlists" for math content. As illustrated in Figure 18, when the user works their way through the problems in a given collection, personalized metadata (or, more precisely, *paradata* [§4.4, p. 57]) shows up in a field labeled "My info". If another user adds a review for a contributed solution, this information will appear as well.

Although collections are just ordered lists, they can also contain other collections, allowing the user to create and share a tree-like outline, or more general network structure of paths through the content. There are not yet any specific UI features for managing sub-collections in PlanetMath, but our early prototype included "Mathematica-like" folding and unfolding interactions, to show and hide various elements on the page (Kohlhase et al., 2011). This would make the user's interaction with complex structures built using the (sub-)collections facility more intuitive.

An "expand all" feature is the obvious next step, since this would give users an experience closer to reading familiar PDF documents. This could be implemented using the content view mode described in connection with Figure 17.

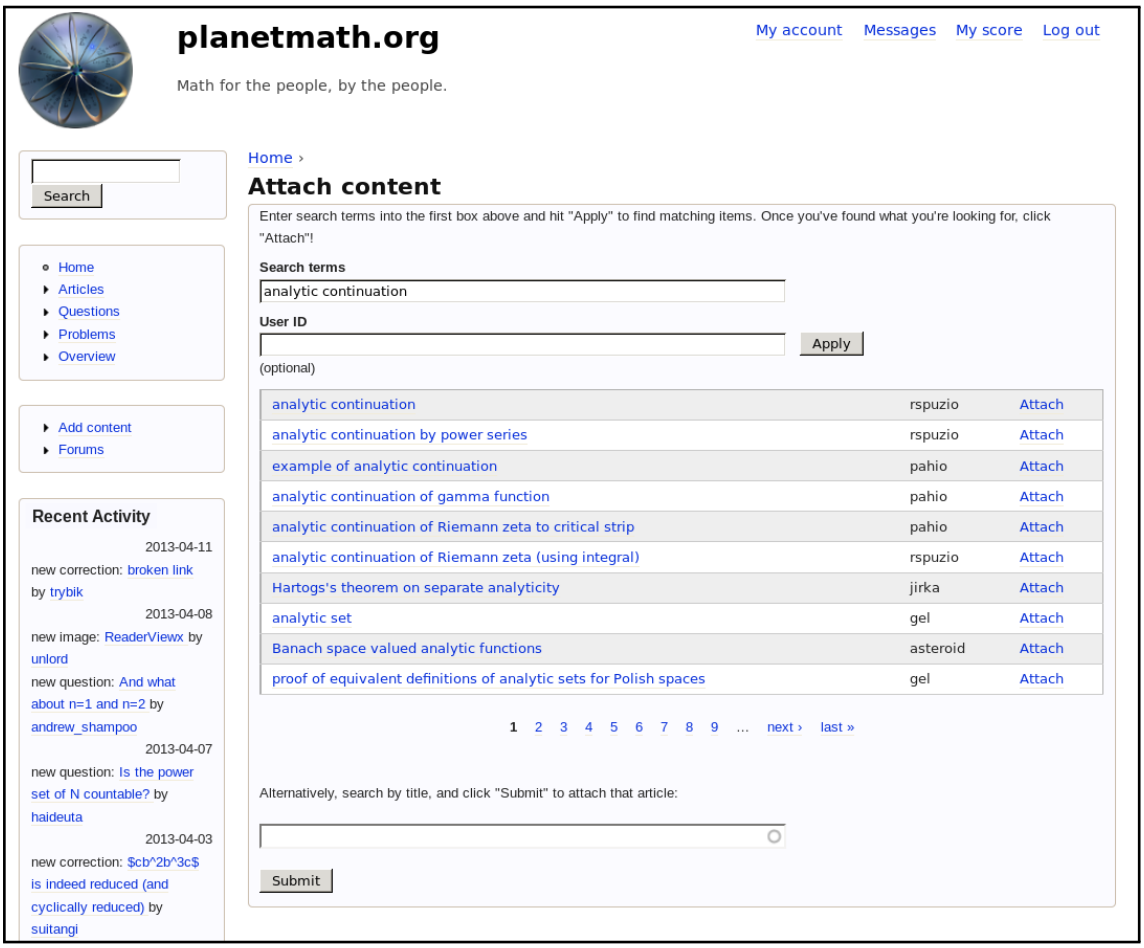

**Figure 19:** *Search being used to add items to a collection*

Figure 19 shows a common UI that is used for building collections, adding content to groups, and also for attaching answers to questions. These interactions were developed in the planetmath_attachable_content module. They make use of dynamic Drupal views that are built using free-text search, which is provided by Drupal's integration with Apache Solr and the associated apachesolr_views module.* Only minor changes were required to index mathematics documents properly,† but integration with a truly mathematics-aware search engine, like MathWebSearch (Kohlhase et al., 2012) remains for future work.

New objects can also be added to a collection by autocompleting on the title, if the title is known – or added *in situ* while browsing by using the link in the "Interact" box (indicated in Figures 15 and 16). New localized interactions are easy to add: so far, there are custom interactions defined for articles, groups, problems, solutions, questions, and collections. The "Interact" box can display different contents for authors/owners and other users; at the moment it does not display at all for non-logged-in users.

*HTTPS://DRUPAL.ORG/PROJECT/APACHESOLR_VIEWS
†HTTPS://DRUPAL.ORG/NODE/1827260

On a whole, the problem solving support is designed with these core features in mind:

- *A low floor*: keywords will be automatically linked to their definitions, which should help users get past a "cold start"; it is also easy to participate just by asking a question; and,
- *A high ceiling*: the collections feature can be used to assemble problem sets or books; users can explore advanced topics, and help others;
- *Support for independent study*: Built-in activity tracking conveys a sense of personal progress, and an increasingly rich collection of metadata and paradata will be useful for recommendations;
- *Support for teachers*: Teachers will be able to use the system to run their own courses – compare earlier classroom experiments run by David Smith (2002) and Robert Milson (2005); Planetary can be used either "as a service" on PlanetMath, or downloaded and further customized in a local installation elsewhere.

***Enhance*** The new problem solving features in PlanetMath/Planetary develop richer dynamic relationships between objects and users by adding the ability to build structure on top of user-contributed materials, and by modeling learning progress.

***Obsolesce*** The collections feature is intended to obsolesce paper-based problem sets. However, with some relatively minor enhancements, it could also make *textbooks* obsolete. PlanetMath content is free and sharable, so it can clearly undercut other offerings in price. Furthermore, unlike textbooks, PlanetMath comes with peer interaction built in.

***Retrieve*** Whereas a hypertext encyclopedia tends to be labyrinthine [§4.5, p. 61], collections can help make the progressive dimension of learning more explicit. They restore the sense of linear order that is familiar from problem sets, textbooks, and state mathematics curricula.

***Reverse*** As PlanetMath builds a more complete catalog of problems, collections, and solutions, we accumulate a machine-readable archive of solution strategies and learning pathways. This archive could potentially be used by artificial agents working on mathematics problems. One application of such a system would be to support the development of a knowledge-rich intelligent mathematics tutoring system. Rather than users teaching the system by adding and structuring content, the system would be actively engaged in teaching users.

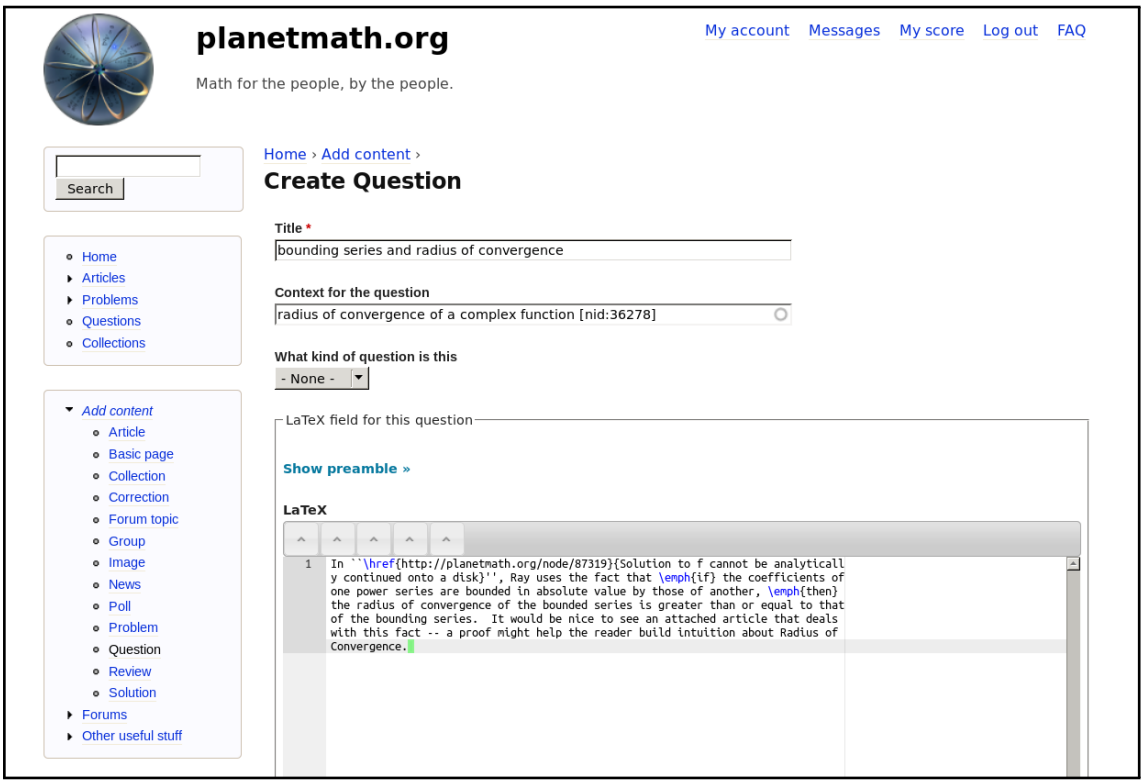

**Figure 20:** *Adding a question*

## 3. Motivate users to contribute problems and discuss solutions

Figure 20 shows a question that is being added "in context" – the user would have gotten here by clicking on the "Ask a question" UI element that appears in the sidebar on articles, problems, collections, and solutions. The user can also ask a question without specifying the context by using the "Add content" menu item from the left sidebar directly; in this case, the "Context" field is hidden from the UI and is left blank when the user presses "*save*."

Questions from across the site show up in a special-purpose feed.* This is one place where we deploy a Drupal *view*. Views offer the possibility for relatively straightforward theming. With more work, we would be able to reproduce many of the same features from StackExchange or its existing open source clone, OSQA.†

Some questions will be useful student-level exercises, like the problems discussed above; but many can be thought of as problems of exposition, and will suggest improvements to the encyclopedia. As with other PlanetMath data types, questions are discussable and can have comments attached – however, *answers* are supposed to be presented in encyclopedia articles, as will be illustrated shortly.

*HTTP://PLANETMATH.ORG/QUESTIONS
†HTTP://WWW.OSQA.NET/

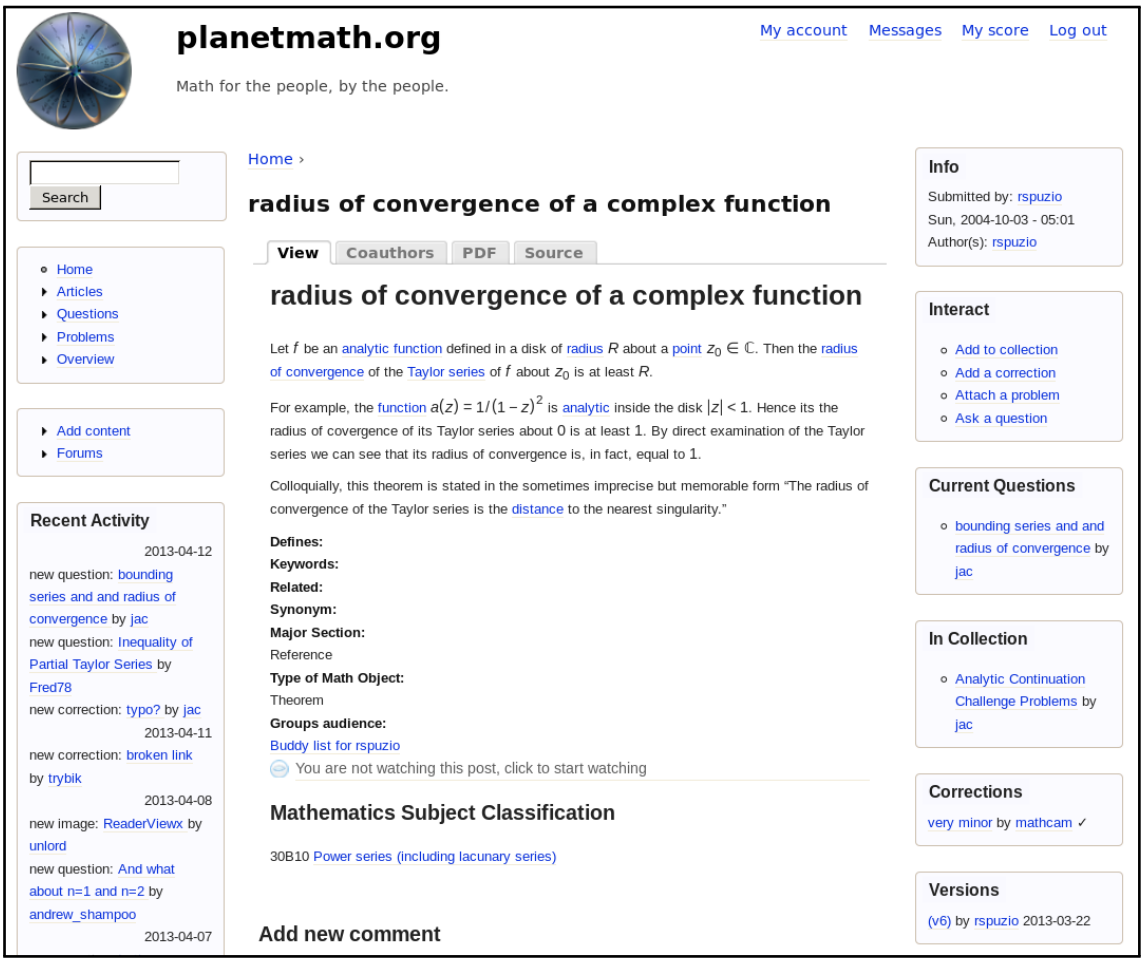

**Figure 21:** *Current questions appear in context*

As depicted in Figure 21, if a question is asked in context, a link to the question shows up in the right-hand sidebar for everyone browsing the relevant object, as a "Current question." New questions also show up in the left-hand sidebar along with other recent activity, and this is persisted across the site, providing a form of light-weight free advertising for users who contribute questions.

Using more refined notions of context, we could adapt this model, so that recent activity would show up sorted by MSC topic. As we shall see in Chapter 9, there are many reasons to reconsider PlanetMath's current orientation towards only the most-global and most-local contexts.

Although contextual questions serve a similar functional role to that of corrections, they are meant to appeal to a more naive reader. A flow of naive questions may a very good way to find and address flaws in exposition. This is consistent with the view that "*the best way to learn is to teach*" (Luk & Wang, 2012). Any constructive reader interaction should help to enhance quality "at the boundary" of author-controlled articles; *cf.* [§1.2, p. 5].

**Figure 22:** *Making improvements to the encyclopedia when answering a question*

As mentioned above, in the question answering model deployed on PlanetMath, all answers are supposed to be supplied in encyclopedia articles. When a contributor indicates that they would like to answer a question, they are presented with an interface like the one in Figure 22. This is the interface from the planetmath_attachable_content module, similar to what was shown in Figure 19. Additional explanatory text and a link are presented when the user indicates that they want to answer a question:

> *The way question answering works around here is that answers are found in encyclopedia articles! If you can't find an existing article that answers the question using the tools below, you can* ***create one*** *and it will be automatically attached as the answer when it's saved.*
>
> planetmath_attachable_content module, emphasis indicates hyperlink

The answerer can either point to an existing article, and add a brief memorandum to the reader – or add a new article. In practice, many users seemed to find this aspect of the interaction confusing. Contributed questions were often answered in *comments* attached to the question, rather than by connecting the question to articles. This does not immediately invalidate the idea of using questions to improve the encyclopedia, but does suggest that the workflow will need to be streamlined. As another approach, one that is particularly interesting in light of the fact that a highly-effective workflow related to question answering already exists on sites like math.stackexchange.com and MathOverflow, various integrations with these sites may be worth pursuing. For example, it should be possible to develop machine learning techniques that provide automated or semi-automated means of connecting questions (and answers) to relevant articles.

***Enhance*** With the introduction of an explicit "question" object, texts contributed to the site start to become more explicitly typed. This moves in the direction of the ontologies for argumentation developed by Christoph Lange (Lange et al., 2008); (Lange, 2011, Chapter 3).

***Obsolesce*** Questions may contribute to obsolescing the old corrections mechanism, at least in part. The question-answering mechanism makes the explicit point that unclear aspects of one article may be explained better in another. The question mechanism also directly obsolesces the old "requests" mechanism from PlanetMath/Noösphere – old requests are mapped into the new system as a question sub-type.

***Retrieve*** Unlike other Q&A sites, wiki discussion pages, or the combination of Q&A with wikis, this system couples questions closely with content. This restores a spirit of camaraderie to the process of addressing user concerns, and points in the direction of collaborative R&D instead of simply Q&A. In short, it retrieves a robust sense of "We". (Compare Table 2 [§3.1, p. 35].)

***Reverse*** Once many questions have been asked and answered, there will be less reason to ask questions anew, since the old answers can just be read. If pushed far enough, the question-answering tool will produce a set of very clear expositions, in the form of repeatable instruction sets. More aspects of the mathematical experience would become algorithmatic – comparable, perhaps, to sewing patterns, cooking recipes, or driving directions.

## 4. Support mathematical meaning making

Two new features of Planetary are particularly geared towards meaning making. A new gallery allows users to share images between articles. Formerly, in Noösphere, each article had its own "file box", to which images could be added. This was useful for adding images to individual articles, but it did not provide a central place for learning about and discussing mathematical images. As noted by legacy users (Figure 13), making these images can be quite a challenging process, often involving custom scripting or programming. The current gallery provides the early beginning of a strategy to address these issues. Groups and collections are intended to address several aspects of meaning making that were identified in the research literature. In short, collections are useful for structuring content, while groups are useful for structuring activities. Planetary includes three kinds of groups: teams, buddy lists, and co-author groups. Groups provide a more intuitive way to control permissions than Noösphere's old UNIX-like Access Control Lists – and they also give a platform on which to continue building features that offer improved support for organizing around shared interests.

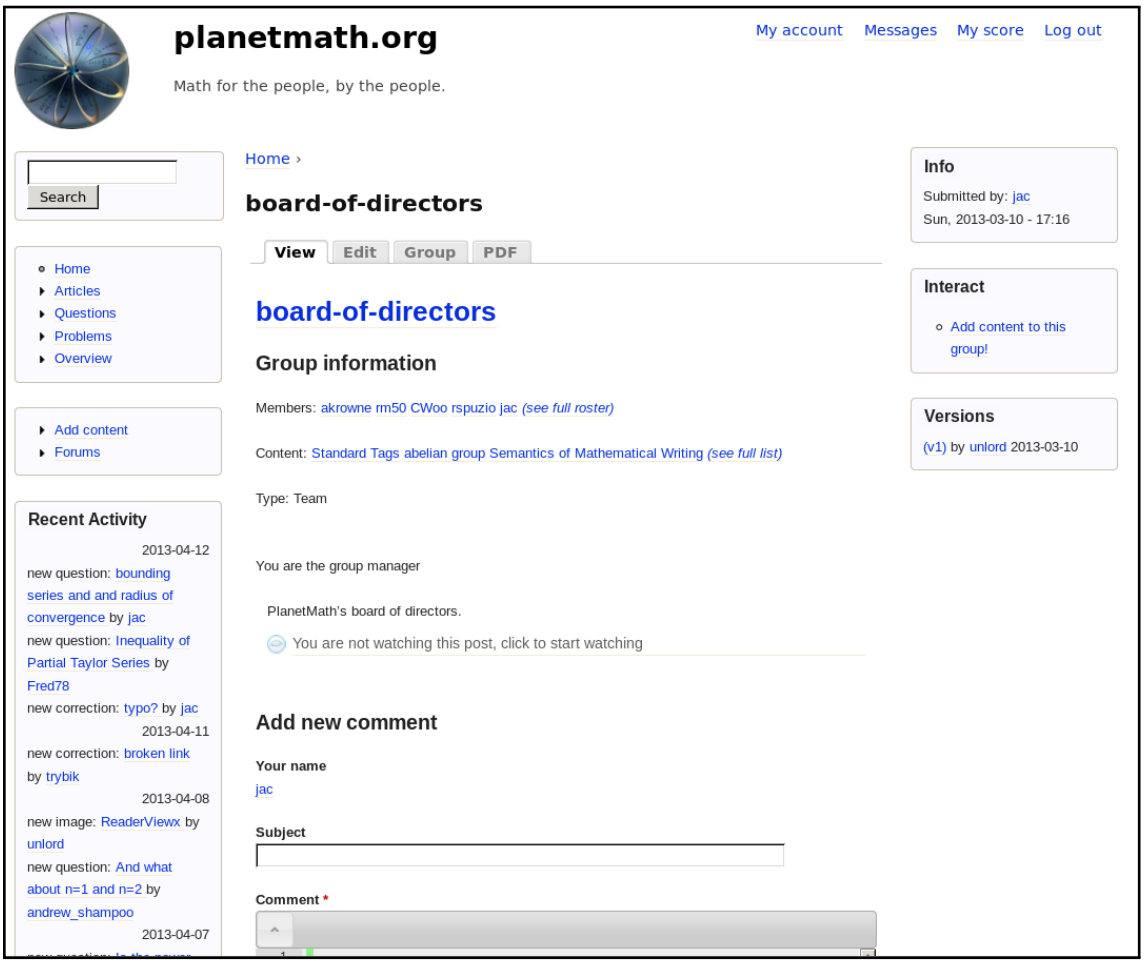

**Figure 23:** *Groups workflow: a team's shared content*

Figure 23 shows a team's content. Any content that is added to a team is made editable by all of that team's members – content can only be added to a group by someone who already has editing permissions. Buddy lists are similar. The members of an individual's buddy list have write access to all of his or her articles. Optionally, a team can be given access, instead of a list of individuals. In particular, if a user wants to give everyone access to their articles, they can designate the World Writeable team as their buddy list.

Co-author groups are specified on a per article basis. Permission to edit an article granted via one of the mechanisms described above *does not* automatically make you a "coauthor," although all edits are recorded in the article's revision history. This allows trusted members of a buddy list or team to make small corrections, without assuming full co-author status. Groups were implemented using Drupal's Organic Groups module.* Various desirable enhancements (like per-group forums and mailing lists) are available as contributed modules, but are not always well supported. Drupal Commons is a suite of modules, also using og, that could provide further enhancements or inspiration.†

*HTTPS://DRUPAL.ORG/PROJECT/OG
†HTTPS://DRUPAL.ORG/PROJECT/COMMONS

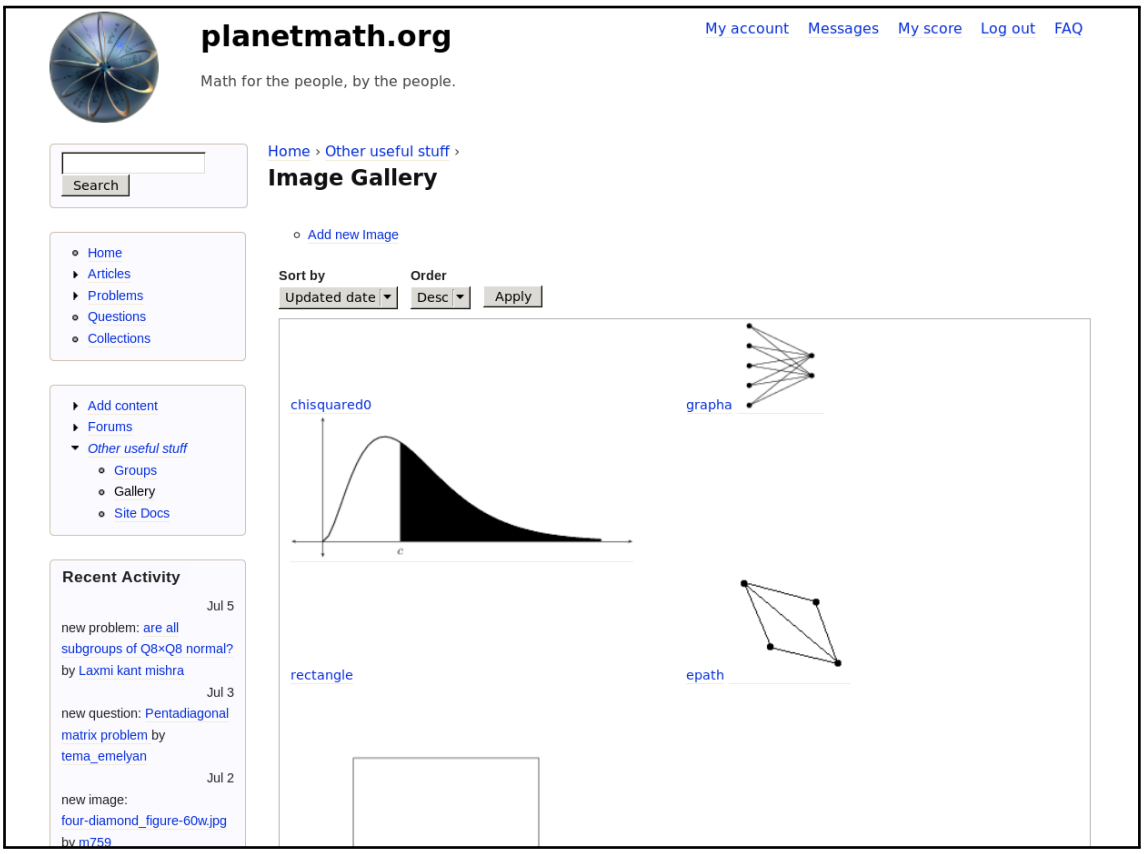

**Figure 24:** *A page from the new image gallery*

Figure 24 shows a page from the new image gallery. The look and feel is currently quite basic: in fact, the gallery is implemented as another Drupal view. Individual images can be included in articles with the LaTeX `\includegraphics` command. When including an image in an article, LaTeXML also deposits RDFa into the page to indicate the inclusion relation to downstream processes. In general, RDFa is useful when we need explicitly work with semantic details of user-contributed materials that would otherwise remain hidden in text. To illustrate one potential application: Since we know which articles use a given image, it would be possible to bring up images in search results by using the texts from the articles that include a given image as a source of index terms in the search engine. A content-focused next step would be to enhance images with instructions on how to generate the image: this is one place where a large set of examples would be very useful. Some recent thinkers on mathematics education have proposed to expand the typical acronym "STEM" (Science, Technology, Engineering, and Mathematics) to "STEAM" (Science, Technology, Engineering, Arts, and Mathematics) (Robelen, 2011). The current gallery is a modest foray into this space. It is also a prototype for other kinds of "shared" objects, for instance a centralized bibliography that would include citations from across the website in one database.

***Enhance*** Groups are designed to help people organize according to their interests. The notion is that it will be easier to integrate user contributions to smaller domains, with the benefit of support from local experts. The gallery, or subsequent extensions, are analogous insofar as images that are shared between articles become a place to organize further work.

***Obsolesce*** Groups partially obsolesce (or at least, make increasingly redundant) PlanetMath's front page, with its stream of posts from across the site. Relative to most specific goals, activity on a per-group or per-topic level is likely to be more coherent and in that sense, more meaningful.

***Retrieve*** Groups offer the sense of a sub-system that is smaller than the whole, but larger than the individual. The aim with features like this is to retrieve a meaningful sense of relationship or even community.

***Reverse*** If groups become strong in their own right, more than bringing people together, they could instead break up into little balkanized islands.

## 5. Support behavior tracking and semantic modeling

The reader will note that the "goal" and "strategy" data types proposed in Figure 1 were not implemented as specific data types. On the other hand, we've built features that give us the foundation for understanding goals and strategies as they are embodied in groups and collections. Thus, for instance, personal goals could be directly modeled as a collection of "things I'm working on." Paradata begins to convey a sense of progress. Collections can also be used to specify a sharable localized learning project, in the form of a reading list that helps build an understanding of a given topic. Teams and projects, along with an associated division of labor focused will be important if site contributors are going to successfully collaborate to build a rich paragogical learning environment. This point will be developed in more detail in Chapter 9.

At the level of domain modeling, one place to begin is with the Mathematics Subject Classification (MSC) is a taxonomic domain model for mathematics. Since the early days of PlanetMath, it has provided a way to browse the site's content "by subject." Reimplementing PlanetMath's MSC browser was an opportunity to develop and demo an integration between Drupal, LaTeXML, and the Virtuoso triple store (Lange et al., 2012), a first step toward exposing more of PlanetMath as Linked Open Data. This infrastructure is not yet integrated with the site's features for behavior tracking, although it would be desirable to do so. This applies to both collection-level paradata described above, and to site-wide activity tracking that uses the userpoints module.

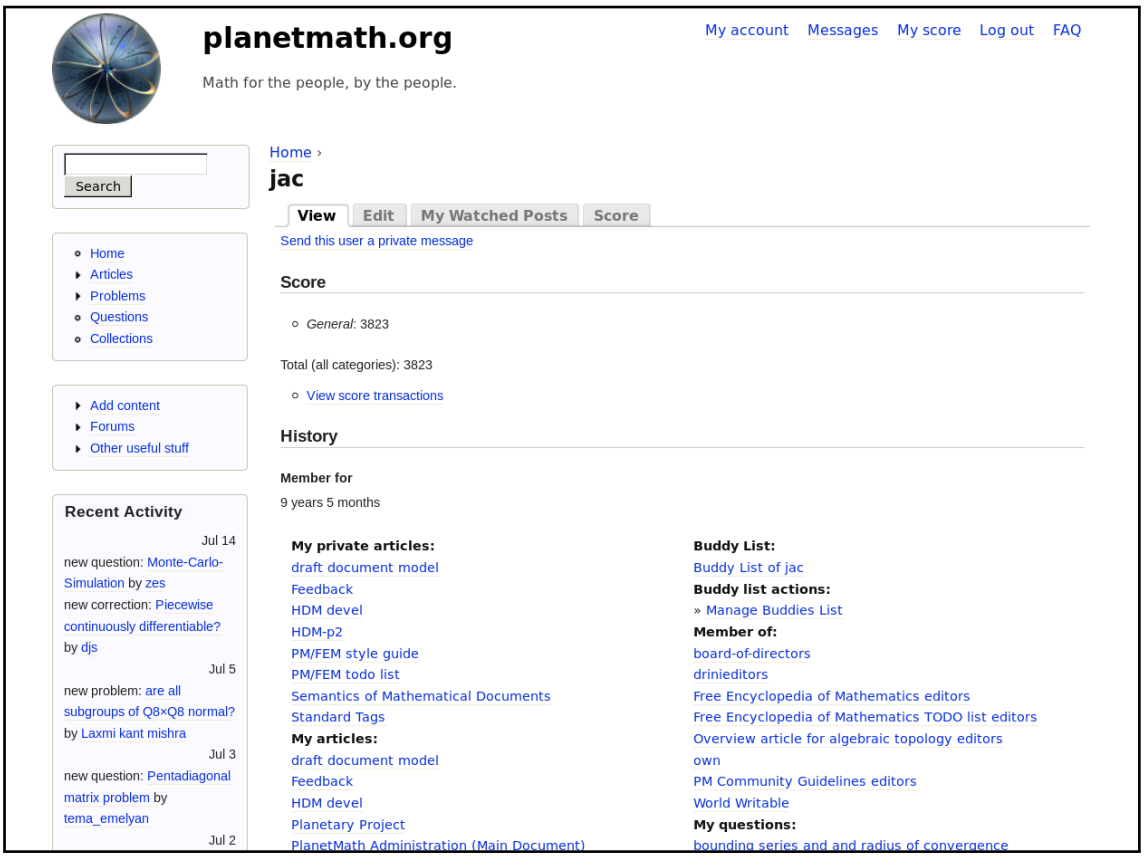

**Figure 25:** *User homepage: showing contributed content and the new buddy list feature*

The user homepage provides a simple listing of the user's contributed content (Figure 25). The user's private articles are only shown if the person viewing the user page is either the user that the page describes or a site admin. Basic biographical information appears at the bottom of the profile page, if the user chooses to supply it.

The user homepage includes links for managing the user's buddy list, as described above. It also includes links for managing watched pages and for sending private messages, which are supplied by the watcher and privatemsg modules, respectively.[*,†] The user's score is managed via the userpoints module; a summary of point-scoring activities is available via the "Score" tab on the user page.[‡] Editing the user page gives the user control over default settings that do not appear in this screenshot, including control over whether or not Planetary will use userpoints to track page reading.

Since some users have contributed hundreds of articles, a more ideal system would include tabs, tags, and other mechanisms for interactively organizing contributed content. This would help users keep track of and manage their contributed material, and help them control how it appears to others.

[*] HTTPS://DRUPAL.ORG/PROJECT/WATCHER
[†] HTTPS://DRUPAL.ORG/PROJECT/PRIVATEMSG
[‡] HTTPS://DRUPAL.ORG/PROJECT/USERPOINTS

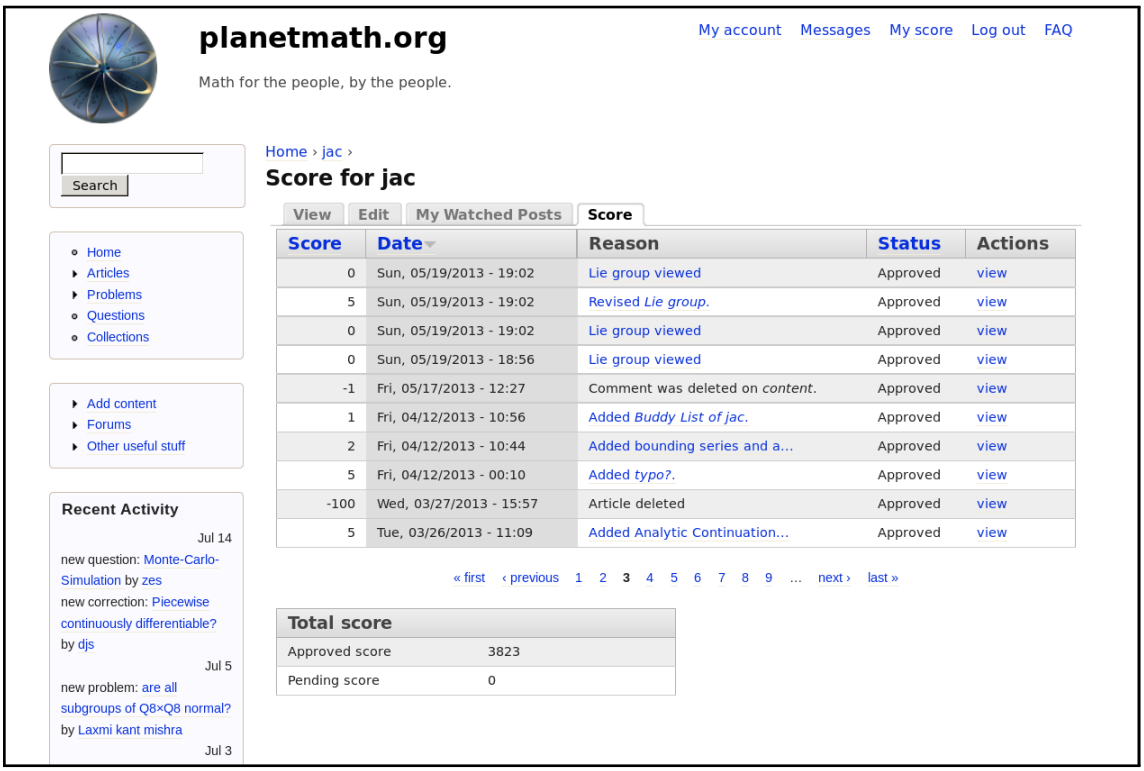

**Figure 26:** *Tracking individual actions with the* userpoints *module*

Figure 26 shows one of the pages from the "Score" tab, which contains a detailed breakdown of the user's contributions to the site. If the user has not opted out of page tracking, page reads will appear in the history with a contributed value of zero. Assigning and adding custom point values that correspond to particular interactions is quite easy with the userpoints module, which provides a function expressly for this purpose (`userpoints_userpointsapi`).

This record includes all of the substantial actions of the users, in some cases going back over a decade (although page reads were not logged in Noösphere). Additional interaction logging provides more data that is amenable to analysis using techniques from Chapter 6. However, to be useful within that framework, the data needs to be separated into vectors specifying the "treatment" and the "effect." This analysis could be made easier if activities were partitioned into meaningful "episodes," rather than simply collected into a large body of potentially unrelated work. Without user intervention, identifying the meaningful episodes and relevant causal factors remains a research topic, although it is one that has been investigated for some time; *cf.* (Faro & Giordano, 1997). One immediately useful idea at the level of user interface would be to display the history of interactions visually, using a module like timeline or views_timelinejs.[*,†]

[*] HTTPS://DRUPAL.ORG/PROJECT/TIMELINE
[†] HTTPS://DRUPAL.ORG/PROJECT/VIEWS_TIMELINEJS

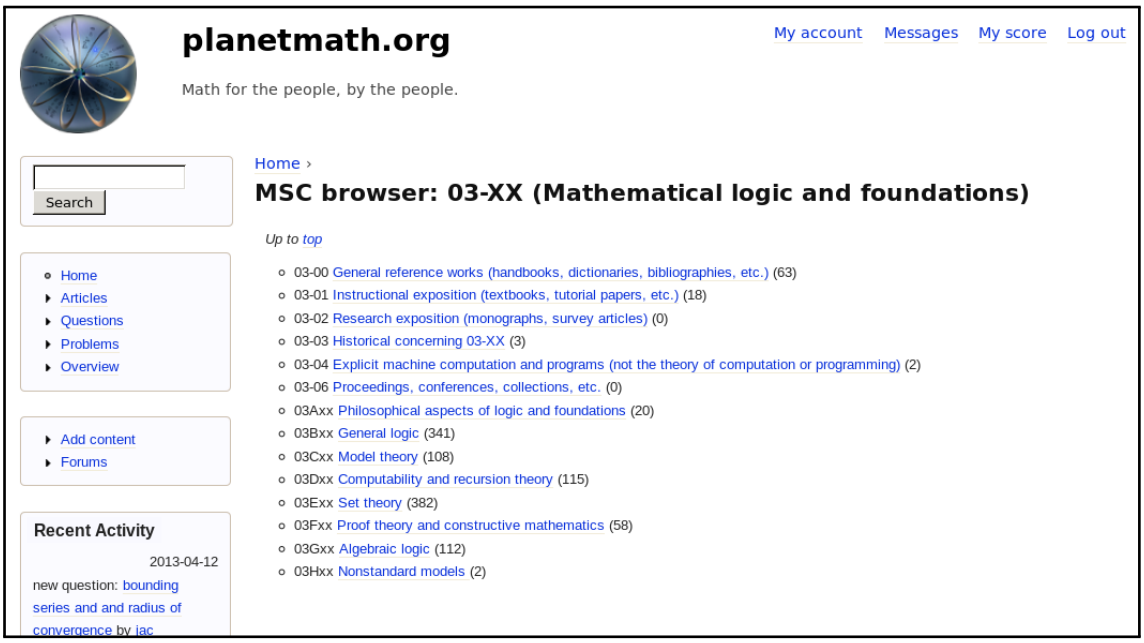

**Figure 27:** *Browsing articles via the Mathematics Subject Classification*

The primary source of top-down structure in PlanetMath/Noösphere was the Mathematics Subject Classification. This system has been replicated in Planetary, but with a new backend that will allow considerable expansion. Figure 27 shows the user browsing the encyclopedia by subject.

For the MSC implementation, we opted not to use Drupal's built-in support for taxonomies,* but instead used the new representation of the MSC as a Simple Knowledge Organization System (SKOS) ontology (Lange et al., 2012), served by an instance of the Virtuoso triple store that we connected to Drupal. Browsing the MSC generates pages and counts articles in various categories using SPARQL queries (Figure 27 shows the category 03-XX and the number of articles in each of its subcategories). The SKOS version of the MSC now includes MathML and multi-lingual category labels. Since the MSC is a core navigation feature, this is an important step towards eventual internationalization of the site.

Drupal serves pages as HTML+RDFa, where the RDFa we're most interested in is generated by LaTeXML from the LaTeX source code, which is further enhanced with links by NNexus. When pages are saved, we run a hook in the new pyrdfa module, which is a wrapper for a local instance of the pyRDFa distiller.† The distilled metadata is then sent to Virtuoso. This allows the system to keep track of which pages link to one another, which articles include which images, which articles are in a given category in the MSC, and to keep track of other provenance-style metadata like author and title.

*https://drupal.org/documentation/modules/taxonomy
†http://www.w3.org/2012/pyRdfa/

Using a triple store opens the way to clever ways to browse and recommend content, for instance, using nearby MSC categories to find related problems. We may also be able to use NNexus to assign MSC classes to otherwise unclassified texts, like forum posts and contributed problems, by clustering the MSC classes of the text's technical keywords. We could then index this content in subject-specific feeds, or attach related forum posts to similar articles or problems as a light-weight recommendation. One of the key issues here is disambiguation of terms with multiple technical definitions; *cf.* (Ratinov, Roth, Downey, & Anderson, 2011).

As mentioned above, currently quite a bit of relational metadata (and paradata) is maintained in Drupal and the underlying MySQL database rather than the triple store. This includes personal history data gathered with the userpoints module, and the hypertextual network of interlinked articles, problems, and solutions. This additional data will eventually be required for inference and recommendation facilities; the approach taken by Mulholland et al. (2013) is similar, and relevant code for moving data to and from the triple store could be reused.[*,†] Once we have a large enough collection of problems with induced MSC categories and depths, we should be able to recommend easier or harder related problems, taking both individual and aggregate paradata into account [§2.3, p. 31]. These models could build on literature related to adaptive testing (van der Linden & Glas, 2000) and the psychology of the "*growth mindset*" (Dweck, 2000).

***Enhance*** More explicit object types together with more data on user interactions adds to our ability to use diagnostic tools, like the one described in Chapter 6. Additional user data around problem solving and peer support could provide the basis for a detailed study of learning-related effects.

***Obsolesce*** Detailed record-keeping on PlanetMath could potentially obsolesce mechanisms like the course transcript or list of publications. As a history of work, the data we can gather resolves to a finer level of detail than either of these.

***Retrieve*** As the system gathers more information about individual contributions, we gain a better picture of who our users are. A user's interaction history should not simply be thought of in terms of pre-determined "badges" or "achievements." It provides something more like the index to a laboratory notebook; *cf.* Bradley (2009).

***Reverse*** If activity on PlanetMath becomes reified as a mechanism for producing value, we may see further effort expended towards mining this value, after the manner of the computations that drive the market for Bitcoins.

## 8.5 Preliminary system evaluation

A user-focused evaluation of the system is detailed in the next chapter; here the focus is on the technical aspects of the system in their own right.

When compared with Noösphere, Planetary is much easier to install, configure, and extend. Drupal's profile subsystem allows Planetary to be set up "out of the box" as a course management tool, or as the home to a larger PlanetMath-like learning community. Drupal's content management features, like the ones that we've used to build the groups, collections, and problem set workflows, help to set Planetary apart from other mathematics-capable tools. In addition to documentation generated by our team, many members of the worldwide Drupal developer community are happy to help new Drupal developers. The features we've developed cast PlanetMath's original mission – to be "*a central repository for mathematical knowledge on the web, with a pedagogical slant*" – in a new light.* Several legacy feature requests have been addressed in the process – and work on others is in progress.†

One could argue that the *combination* of features from other sites (*e.g.* Wikipedia plus StackExchange) could provide a system with the same functionality as PlanetMath. To some approximation, that is certainly true. This begs the question: what benefits do we get from putting various features under one roof, with a purpose-built system? The primary benefit is that integrative functions can be performed more easily. This is demonstrated well with the new collections feature. In the future, it would be attractive to increasingly integrate the platform with what others are doing elsewhere on the internet. For example, NNexus could be used to index mathematics blogs, and provide a topic-specific blogroll attached to each page in PlanetMath's encyclopedia (Ginev & Corneli, 2014): recall that the usual meaning of "planet" on the blogosphere is planet-as-aggregator.

I would cite two particular points of difficulty associated with using Drupal 7 as the basis of the new site:

1. *Drupal is known to have a steep learning curve.* This slowed our progress at the start, and sometimes things that should in theory be simple still ended up not working at all (thus, for example, dynamically changing menu items would work for a while, but then crash the site, so those features had to be turned off).

2. *We had to patch Drupal's core.* This is justifiably "taboo" amongst Drupal programmers, since it makes updating the site difficult, but we needed a new hook (`hook_post_save`) to supply our RDFa extractor with *rendered* HTML+RDFa; we also

*http://planetmath.org/history.html

†https://github.com/holtzermann17/planetmath-docs/issues/62

needed to modify Drupal's database interface to add support for the characters that are needed to display mathematical symbols.

Some of the technical issues will be resolved in Drupal 8 – but the system doesn't show signs of becoming simpler to learn. Luckily, the Planetary developer team has accrued significant wisdom, some of which can be passed along to future contributors. There are some "add-ons" for Drupal that are quite helpful for development work – for example, Drupal is fully scriptable via Drush,* and it can be interacted with using a Read-Eval-Print Loop (REPL), care of Boris.†

As a matter of building a usable system that can also be the basis for future work, the project has been a technical success. There are many places where new features, ranging from format shifting to research on recommenders for learning would be useful. Planetary is interesting partly because of what it makes possible – including the user study presented in the following chapter, which will help evaluate and better understand the paragogical model embodied in PlanetMath/Planetary. Future work on the system will progress subject to demand. As one small example: the activity data we store is similar to the format proposed in the ActivityStreams project, but use-cases for downstream consumption of data about activities on PlanetMath are not yet entirely clear, so we have not yet put effort into serving bona fide Activity Streams.‡ When the use case is there, the system is ready to adapt accordingly.

## 8.6 Summary

The Planetary system is an extensible open source platform for doing mathematics on the web. PlanetMath, which was previously oriented around authoring and editing a mathematical reference work, has been rebuilt using the Planetary platform. The new system hosts online problem solving interactions in a knowledge-rich, wiki-like environment. New features include custom collections, which can be used to build reading lists and interactive problem sets. Planetary records information about problem solving and other interactions, making it a useful tool for learning more about the way people learn mathematics.

While PlanetMath/Noösphere considered logical correctness, encyclopedic coverage, and expository quality to be matters of importance, mathematical problem solving did not receive explicit attention. The implementation work presented in this chapter opens new horizons for the PlanetMath community, with a focus on relevance and usefulness for a broader population of users. The development work has been informed by con-

*http://drush.ws/docs/shellscripts.html

†https://github.com/tobiassjosten/boris-loader

‡http://activitystrea.ms

tact with system users and stakeholders and by the theory of paragogy developed in earlier chapters. As a computer program, Planetary must follow strict rules; if anything, mathematics "*is much less formally complete and precise*" (Thurston, 1994). However, its expressive thickness derives not from the fact that all of the semicolons are in the right place and most if not all of the critical bugs have been eliminated – although this is certainly important – but rather from the fact that it can now be used, critiqued, and improved.

The discussion of screenshots framed using McLuhan's tetrad helps to add media-theoretic depth to the design dimensions and user desiderata discussed earlier in the chapter. The screenshots are, in a way, figurative depictions of typical mathematical contexts, but with a difference. In offline mathematics we are familiar with scratch paper, journals, and blackboards for building, sharing, and discussing mental models; gradebooks, transcripts, and CVs for keeping track of progress; problem sets, textbooks, and monographs for organizing learning materials; and libraries for browsing existing mathematical works. Planetary does not reproduce these technologies flawlessly, but the parallel online context has the advantage of being connected to a robust meta-level discourse and an ongoing process of technological change. This chapter has described the progress from design elements to working code deployed on a public website. The next chapter will explore the system's underlying dynamics in more detail, by examining the user experience.

# 9 User Evaluation

**Qualitative findings from a user study after the public release of the new system demonstrate the feasibility of the paragogical approach, while suggesting a range of improvements to the software that will be needed for the project to successfully scale up – in particular, the further re-structuring of PlanetMath's activities into "sub-projects."**

## 9.1 Research design

Planetary was deployed to PlanetMath.org on February 13, 2013. In April, I began recruiting participants for a 10 day study on PlanetMath. From emails sent to 15 all-time top-scoring and 30 other recently active PlanetMath users, I successfully recruited three persons. I also recruited three postgraduate students in mathematics at The Open University, contacted through their department.* The main question I focused on in the interviews was: would PlanetMath be relevant to the way you study and do mathematics? I also tried to elicit any ideas that might help to improve the site. Participants in the study obliged, with quite a bit of constructive critical feedback about the system. For example, one noted his resistance to creating collections, another talked about difficulties working with LaTeX, a third pointed out that PlanetMath would be more useful if it provided a feature for blog hosting, a fourth suggested new features for navigation. Figures 28 and 29 sum up the research design that helped to give order to this type of feedback, using a visual metaphor. The study aims to describe the relationship of system features to emergent patterns of use, here visualized as "paths in the grass."

*One person also joined in response to an announcement in the *Peeragogy in Action* Google+ community, but he dropped out of the study before completing an interview.

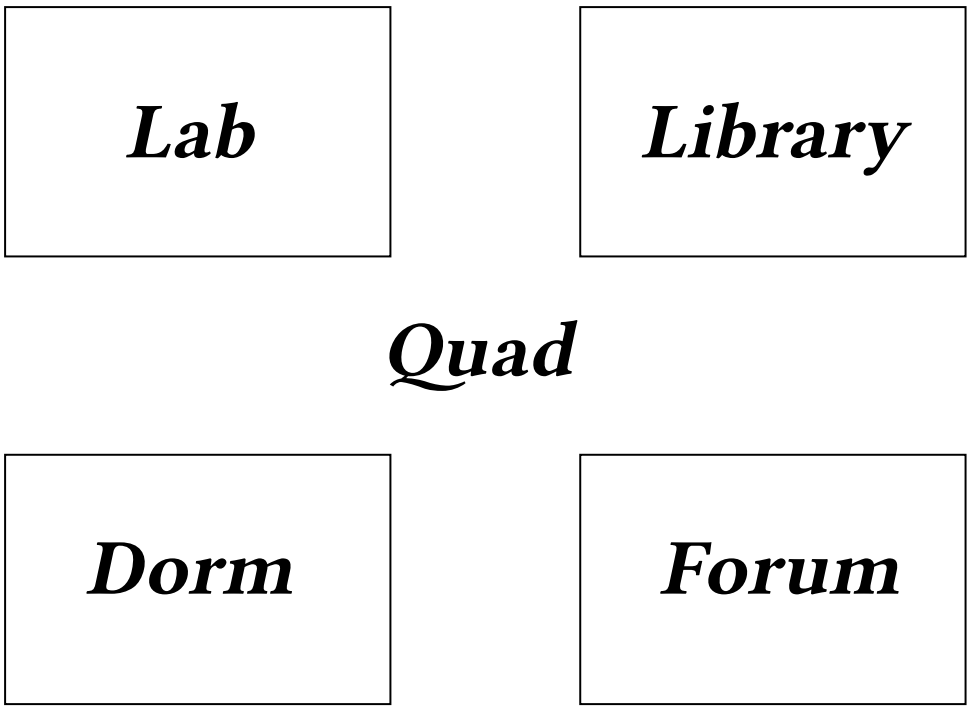

**Figure 28:** *Map of a virtual campus*

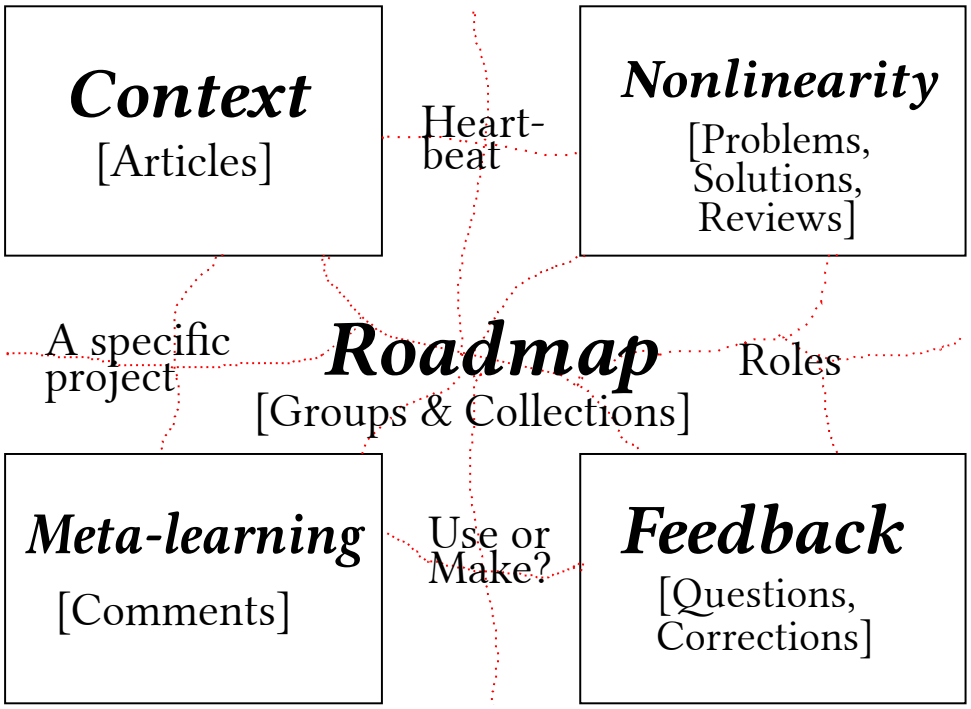

**Figure 29:** *Peeragogy patterns as loci for "paths in the grass"*

The Peeragogy project's catalog of patterns for peer learning (summarized in Table 13 [§5.2, p. 79]), which is used to seed the current study. If actual behavior were as depicted in Figure 29, we would expect to see people moving between "Articles" and "Problems" by way of "*A specific project*", or from "Question" to "Collection" by way of a division of labor among several "*Roles*." At a narrative level, this makes a certain amount of sense. In practice, the emergent structure of use may be more elaborate. More than a collection of hypotheses, Figure 29 represents a "meta-model" that can be used to identify the dynamic patterns of use that emerge within in a socio-technical system.

David Cavallo explained the idea of *emergent design* as a practice of "*probing for skills and knowledge resident in a community and using these as bridges to new content*" (Cavallo, 2000A). The aim here is to find not just new content, but new form – which necessarily involves transformation.

The study's phases are described in Table 19. In the first phase, participants (Table 20) attended a focus group where the study was described in detail, and where participants were asked to describe their mathematical backgrounds and to say what interested them about the study. I also walked them through a sequence of screenshots similar to those in Chapter 8. In the second phase, participants tried the new features of Planetary, on the public PlanetMath.org website. In the third phase, I conducted individual interviews. The participants were recruited in two cadres, so these three phases all ran twice (on May 2, 2013 and May 15, 2013). Participants were awarded a £32 Amazon.co.uk voucher upon completion of the study.

The analysis focuses on material gathered from the interviews; selected quotes appear in Appendix D. The initial analysis connects this feedback to the specific features of Planetary by way of the dimensions of design discussed in Chapter 8. Patterns offer another heuristic method to understand and organize new ideas coming from users. At the outset, several patterns (*Heartbeat*, *Roles*, *Use or make*, *A Specific Project*, and *Roadmap*) that came up particularly frequently in discussions in the Peeragogy project seemed likely to describe the user experience here. During interviews, I used the layout from Figure 29 as a template for visual notetaking.

A pattern-based analysis is rigorous in the sense that either the existing patterns match the topics under discussion, or new patterns should emerge. Design patterns are far from being a "universal" symbolic language in the Leibniz sense: nevertheless they can be used in the spirit of *mathesis universalis* as understood by Deleuze; cf. (Deleuze, 1968, pp. 229–230, 241). Design patterns can help build culture where before there were only constraints, symbols where before there was only a landscape; *cf.* [§1.4, p. 10]. In the course of analysis, the user evaluation of the site was encapsulated in three new design patterns that contribute to a new, emergent, design for the site, including concrete indications of "What's Next".

| | | |
|---|---|---|
| **1** | In an initial focus group, I will present the background of this study. | I will aim to discern what the *Roadmap* for individual participants looks like. |
| **2** | I explain the tasks that I would like people to try over a 10 day period, and explain that I will be available for discussion in the forum or privately by email. | I will aim to discern whether people use the four basic patterns (*Heartbeat*, *Roles*, *Use or make*, *A Specific Project*) as they orient themselves to the new software. |
| **3** | I will meet with each of the participants for an individual debriefing after the 10 days has passed. | I will aim to discern whether people use any other more refined patterns as they used the tools. |

**Table 19:** *Phases of the structured component of the user evaluation*

|---|---|
| **AA** | UK resident, male, chemistry background, currently working in media; hoping to enroll in the Open University's mathematics masters degree (contacted through PlanetMath) |
| **AB** | UK resident, female, current postgraduate student in mathematics (contacted through OU mathememathics department) |
| **AC** | German resident, male, mathematics PhD, staff scientist and programmer, long-time PlanetMath user (contacted through PlanetMath) |
| **RSP** | US resident, male, physics PhD, long-time PlanetMath user and active volunteer (Raymond S. Puzio, requested non-anonymity) |
| **BA** | UK resident, male, engineering background, enrolled in the Open University's mathematics masters program (contacted through OU mathematics department) |
| **BB** | UK resident, female, engineering and software background, enrolled in the Open University's mathematics masters program (contacted through OU mathematics department) |
| **BC** | UK resident, male, teaching and media background (contacted through the "Peeragogy in Action" Google+ community; BC dropped out of the study partway through) |

**Table 20:** *Study participants*

## 9.2 Thematic analysis

Individual interviews offered the most information and are examined in detail in this section. Detailed quotes from the interviews are presented in Appendix D and are referenced here in square brackets.* The analysis also draws on observation of participant interaction with the tool, as well as forum posts and emails exchanged with participants during the study. The most useful way to begin to organize the analysis is under the headings coming from the initial dimensions of the design (Chapter 8), and to think in terms of the concrete system features that instantiated this design (Figure 14 [§8.3, p. 114]). The key ideas are collected into emergent themes.

### 1. A special-purpose tool customized to suit the challenges of learning mathematics

**"Necessary but not sufficient"** In our interview, **AA** – who came to PlanetMath with mostly undergraduate-level questions – said that the site is only as good as the *people* who use it. **AB** – who was thinking about research-level problems – suggested that it is only as useful as the *content* that it provides. Working software is clearly another "necessary but not sufficient" criterion. A model devised by **RSP**, connected with earlier discussions among core volunteers in the PlanetMath project, came up again in our interview [RSP1]. A schematic rendition of this model is presented in Figure 30. *Content* and *Community* features are familiar from other social websites. A *Catalog* is similar to what one finds in libraries: a resource that provides pointers to other available resources. **RSP** is particularly interested in using existing library catalogs to find additional content that can be used on PlanetMath [RSP2]. Inasmuch as the catalog helps to find content, it represents an essential feature. **BB** repeatedly emphasized the importance of functioning search – otherwise we will have "*masses of very good math, masses of very good theorems and results and definitions and so on*" – that are effectively useless because you can't find the one you need [BB1]. Thus, a tool that supports learning mathematics should at least support these three core features. Two additional components, *Code* and *Organization*, provide the basis for the existence and evolution of such a tool, but most users will not interact with these components directly [RSP1].

**Challenges with writing mathematics** At the moment, the most prominently visible mathematics-specific aspects of the system have to do with *content* – and particularly with entering and displaying mathematical *symbols* in textual form – although mathematical *figures* were also discussed. As it stands, even mathematical symbols presented

*Recordings from **AA** and **AB** are missing due to a problem with the recording software; accordingly, data from these interviews is embedded in diagrammatic form in my handwritten notes. **BC** dropped out of the study before completing an interview.

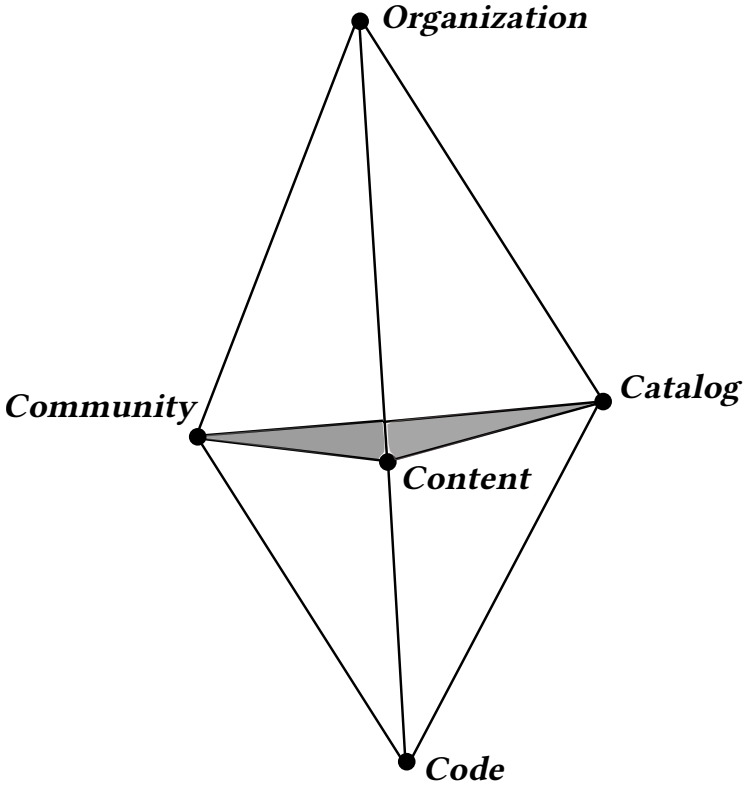

**Figure 30:** *Raymond Puzio's "3C" model, with elaborations from our conversations*

various difficulties for some of the users. **AA**, who was new to LaTeX, emailed me several times during the study asking for typesetting help. **BB** and **BA** were familiar with the "What You See Is What You Get" (WYSIWYG) LaTeX frontend LyX,* having used it to complete their course assignments. They managed with PlanetMath's current web editor, but **BA** indicated that he missed the familiar WYSIWYG workflow. With the current web editor, he felt concerned that the browser might time out, and that he would lose any text that hadn't been saved [BA2].

Currently, LaTeXML "*fatal errors*"† (where no resulting HTML can be generated) aren't reported to the user at all and result in a blank screen, causing a strong sense of uncertainty and doubt when things go wrong – even for an experienced LaTeX user like **AC** [AC1]. On the other hand, **AC** emphasized that having LaTeX itself is quite useful [AC2]. Autosave and auto-preview would not be terribly hard to add to the current PlanetMath editor, particularly since both the editor and the LaTeXML daemon have WebSocket support. Simple point-and-click entry of mathematical formulas would also be an advantage for new users. Novice users might also prefer to use handwritten mathematics (Lo, Edwards, Bokhove, & Davis, 2013). **BA** indicated that scans of handwritten papers can be submitted in Open University courses, which lowers the barrier to participation.

*http://www.lyx.org/

†http://dlmf.nist.gov/LaTeXML/manual/errorcodes/

**"Nice to have"** In the interview with **AB**, we came up with a way in which an improved gallery could be useful for search. She was looking for a paper in graph theory – but wasn't sure what search terms to use, although she knew what the graph she had in mind looked like. Our idea was that if PlanetMath's gallery had more semantic structure, allowing her to find the figure, it could also be used as a way to find the relevant definitions. Currently, however, the gallery needs many basic improvements, and image search does not work at all. **BA** found the workflow of uploading to the gallery difficult and suggested that images wouldn't often be reused and that the global gallery was of limited importance. He suggested to switch to "article-local" interaction with images (as in Noösphere). It should be possible to support intuitive local uploads that integrate with the global gallery. As time goes by, we may see user interest in additional features for remote collaboration, including various mathematics-specific features, like a interactive computer algebra system [RSP3].

## 2. An active and interactive process centered on problem solving

**Progressive problem solving** Several subjects brought up interesting points and questions about the meaning of "problems" and "solutions." This helped to show that the entity relation diagram in Table 10 [§5.2, p. 74] could be made more complete by adding conjectures and partial solutions [AC6]. It seems clear that interactions centered on research problems and textbook problems would be rather different. **BB** outlined an ethical stance on questions about homework problems [BB2] that is very different from **AC**'s orientation towards sharing both questions and partial answers to research problems.

**BB**'s understanding of the right thing to do in the case of *questions about homework problems* was consonant with the design decision to have "answers" be links to encyclopedia articles [BB2], [BB4]. Linking to encyclopedia articles is effectively a hint, indicating relevant and ostenibly common knowledge, which should put the questioner on the right track, but which may still leave them something to work out. However, when it comes to *her own solutions to problems*, like **AC**, **BB** was comfortable with uploading and discussing conjectures and partial solutions as work-in-progress [BB3].

It was also clear that unless users are comfortable sharing incomplete answers, partial, or failed solutions, then this sort of knowledge will be underrepresented – which may represent a missed opportunity for learning (Tsovaltzi et al., 2010). Nevertheless, there is a barrier to overcome. **AB** said she found it nice to be able to help – but she was concerned that if she admitted that she couldn't figure out the answer to a given question, or if she posted an incomplete answer, people would get upset. She reported spending an hour attempting to work out a tricky integration by parts problem that another user had uploaded, before giving up – no trace of this work showed up on the site. Regard-

ing another question having to do with differential equations and interest rates, she said she would have liked to help, but "*I haven't looked at that in years.*" Certain comments from **AB** and **BB** were aligned with an idea that I had previously discussed with the Planetary development team, namely the creation of an Etherpad-like website for mathematics [BB3]. This would be a stand-alone system built using an improved version of the PlanetMath editor for creating ephemeral (potentially anonymous or throw-away) mathematical artifacts, the electronic equivalent to a chalkboard. However, if this collection was (optionally) taggable and searchable, the material could be re-used, and could, furthermore, provide a real-time guide to topics of interest around the site; *cf.* (Corneli, 2010), (Mary, 2013).

**Personal history, constructivism** Planetary currently presents an overview of the user's "History" on the user homepage. It tracks more detailed interactions using the userpoints module, but **AC** found the presentation of this information confusing [AC11]. **BB** pointed out that history is not only important for the user home page, but could be usefully integrated into the browsing experience, using appropriate breadcrumb trails rooted at important topics [BB7]. Meaning making is associated with "constructive" features, and collections represent a light-weight tool for constructive meaning making. Subjects generally agreed that collections provide a useful way to organize material, and also that there were various ways they could be improved, for instance: by adding the ability to "expand all"; by being able to display sub-collections in a nested format; by being able to include links to outside resources; or by adding narrative "glue" between components. For **BB**, who was thinking primarily of reference-related user interactions, PlanetMath's existing narrative *topic articles* that summarize important mathematical topics present a compelling alternative to collections [BB8]. **BA** felt that collections should be managed by someone with a designated "editor" role [BA3].

## 3. Motivate users to contribute problems and discuss solutions

**Regulating learning in a social/mediated context** Although she described herself as "*not very self-motivated*," **BB** seems to be highly motivated in the right context – and she is very interested in understanding how she learns best [BB5]. After our interview, she sent me a description of her own learning patterns [BB6], which seemed to closely match the "*forethought*", "*performance*", and "*self-reflection*" cycle from (Zimmerman, 2002; Zimmerman & Campillo, 2003). As Zimmerman and Campillo (2003) indicate, there are differences between problem solving in "*formal*" and "*informal*" contexts. Although mathematics is a relatively formal domain, PlanetMath can also help people solve a range of "*ill-structured*" informal problems. For example, **AA** was particularly enthusiastic about PlanetMath's potential as a place to network with people with similar interests, but pointed out that there needs to be a "*sense of urgency*" about answering

questions that are uploaded to the site. I mentioned that the StackExchange system seems to have done a good job in that respect. **RSP** also expressed interest in networking [RSP4], but pointed out that simply displaying a log of user activities wouldn't really be sufficient for finding collaborators, since even very prolific contributors "*might not be in the mood to talk about it*" [RSP5]. He suggested that a map of user activity would be more useful if it included more detailed social networking information, beyond just mathematical interests or a state of "co-presence" online [RSP5], [RSP7].

**Comparison with roles in other contexts** People are motivated to use systems that help them achieve their aims. People are relatively *unlikely* to report software bugs if they don't have a sense that the bug reports will be responded to. I encouraged **AC** to point out any software problems he encountered with PlanetMath/Planetary, even though I had to admit that the Planetary development team is not "*available 24/7*," [AC7]. On the software level, if we make it easy to report bugs, if we respond to bug reports, and if we make it easy for others to get involved with the software, then there's a good chance that the software will eventually become satisfying for site users. "Bug reports" and "feature requests" present a useful model, not just for software, but for mathematical content – indeed, this is precisely what *corrections* and *requests* were supposed to accomplish in Noösphere. However it may be time to introduce a new abstraction layer, that helps people discuss and engender more broad-sweeping change (*i.e.*, above the level of individual articles, which is what corrections target). An "open" production model comes with the ability to redesign the platform and content as a work-in-progress. This is quite different from the model used in OU courses, where, for instance, the forum moderator tries to "*dispel any talk*" about the Tutor Marked Assignments [BA6].

## 4. Support mathematical meaning-making

**Readily available feedback** Study participants pointed out in different ways that if there are to be interactions with other people, then people have to show up. **AC**, who had first joined the site around the time of PlanetMath's peak in activity in the mid-2000s (Figure 2 [§2.1, p. 25]) noticed that things were fairly quiet around the site these days [AC3]. He pointed out some questions that the PlanetMath ownership model poses regarding interaction with content once article owners have left the site [AC4]. Relating back to **AA**'s point about a "*sense of urgency*," **AC** noted that it is very important to be able to "watch" a problem, so as to get notifications when its status changes [AC5]. In OU courses, the tutor is available for live help on an individual basis: as **BA** indicated, "*The student can contact them by email, phone – and, um, whatever.*" We can contrast this with the experience in PlanetMath, where, for instance, an active volunteer like **RSP** expresses a somewhat distant hope for time to help newcomers [RSP10].

**Concreteness as a criterion of quality** Concreteness applies at both the system and content levels: people need to know what they can do, and what it means. Some of the study participants found the proliferation of options and types of data on the home page confusing. It seems possible that something like a "start menu" would help people see what they *can do* on PlanetMath – and if someone wants to do something that isn't possible yet, they should be instructed to use the action, *send a message to the developers requesting a new feature.* **BA** described the OU courses he had taken, and told me that he had quit one of them part way through [BA7]. Even though "*some people*" can find their way around functional analysis, his course was presented in a way that made the topic seem "*so abstract*" that he was not able to follow it. **BA**'s experience points to the importance of being able to visualize the topic that is being studied, and understand how it can be applied. Adding concreteness is one "service" that a knowledgeable teacher or mentor can provide – if one is available.

## 5. Support behavior tracking and semantic modeling

**Personalization and localization** **AC** was particularly enthusiastic about the ways in which PlanetMath could, at least in theory, be personalized to the user's interests. In his view, PlanetMath shows more potential in this regard than sites on the StackExchange network [AC8]. This perception is striking particularly because there is still considerable room for improvement in implementing personalization features. Some of these features would be within easy reach, for instance, after the model of dashboard module used on Drupal.org.* **AC**'s perception of personalizability may have to do with PlanetMath's *openness* [AC9] and its subject-specific focus. He also had some specific technical suggestions. One of these was to incorporate blogging tools in PlanetMath user pages [AC10]. **RSP** suggested a similar point, namely, to incorporate familiar social networking tools into user homepages, using a system like Friendica† [RSP6].

One of the ways to localize around specific interests is to "segment" the site, per requests from legacy users, see Figure 13, [§8.2, p. 110]. **BA** suggested that people working at different levels may not need to interact much [BA5]. **BB** made a similar remark that indicated that segmentation would be most useful when combined with a localized, faceted search functionality [BB9]. Connecting this to the theme of personalization, **RSP** pointed out that all of PlanetMath's important features always "localize" to any given user at any given point in time [RSP8], although they may fail to do this gracefully. He noted that individual projects had not been particularly well modeled or well supported in PlanetMath/Noösphere [RSP9].

## 9.3 Pattern analysis

As a secondary level of analysis, the interview data is further analysed in relationship to the Peeragogy pattern catalog (Table 13 [§5.2, p. 79]). The notion of pattern-finding as a process related to, but distinct from abstraction, is described by Richard Gabriel, who emphasizes that the "*patterns and the social process for applying them are designed to produce organic order through piecemeal growth*" (Gabriel, 1996, p. 31). This criterion is here applied to the growth of the pattern language itself. This section draws on the thematic discussion from the previous section, and aligns user feedback with the existing pattern language, in the process of describing three new patterns. A discursive presentation is presented first, followed by a summary using template from Table 11 [§5.2, p. 76] in Tables 21–23, which appear at the end of this section.

### Frontend and Backend

Although mathematics is a relatively formal domain, many of the motivations for using PlanetMath map onto Zimmerman and Campillo's (2003) dimensions of "*informal*" problem solving. Informal problems are "*are personally defined*" and possess "*open-ended boundary conditions*": they are situated within an open world. "Formal" motivations can typically be addressed by a generalized look-up approach: for instance, by reading the manual, or running the algorithm. An acquaintance with the formal features of mathematical problem solving is usually seen as a prerequisite for engaging constructively with the more informal activities of mathematics research, which involves scratch work, serendipity, and various human factors. This dichotomy suggest a new and important pattern, linked to the 3C+2 model developed in conversations with **RSP** (Figure 30). The pattern could be called *Frontend and Backend*. A similar distinction was proposed by Reuben Hersh (1991), after Goffman (1959). Hersh compares the "*front*" of mathematics to the seating area of a restaurant, and the "*back*" with the kitchen. In this metaphor, the suggestion is that the front is misleadingly neat and the back realistically messy. This corresponds with Thurston's perspective on written mathematics [§4.2, p. 49].

However, rather than focusing on degrees of formality, the *Frontend and Backend* pattern is perhaps best understood in relation to the *Newcomer* pattern. Typically one will not expect the user of a system to know how to, or be motivated to, work with backend features until they have mastered at least some of the frontend features. For example, you have to eat before you can cook, and it would be rare to find an auto mechanic who did not know how to drive. David Cavallo (2000B) wrote about an "*engine culture*" in rural Thailand in which structurally open systems brought aspects of what residents of more modernized regions think of as "backend" features into the "frontend". Thai farmers routinely move one engine between different pieces of farm machinery, for

example. In mathematics, textbook problems are stated in terms of a certain vocabulary, but for all but the simplest problems, knowing the definitions of the terms is not enough to solve the problem. One needs to understand how the ideas fit together. The *Frontend and Backend* pattern clearly lends itself to standard service provision, as, for example, in Open University courses. It can also be part of paragogical activity, as in **RSP**'s proposal to focus energy on supporting individual users, by helping them develop a high-quality sub-site on their topic of interest [RSP8], [RSP10]. This would simultaneously inform the development of various replicable backend features, and help raise the profile of the site as a whole. The pattern is in this way associated with *A Specific Project* and with the *Roles* pattern. *Frontend and Backend* also connects with the *instrumental* and *interactional* modes of engagement discussed in Chapter 7 [§7.2, pp. 94-95]. If you only want to know the answer, or if you wish to avail yourself of a service that can be rendered in a transactional manner, then you can usually stay at the level of the frontend. If you want to understand what's really going on – or if the service can only be rendered interactionally – then you may have to take a look at what's happening in the backend.

## Spanning Set

This pattern connects with **BB**'s thoughts about using topic articles as a map to the content. You may be able to get what you need without digging – but if you do need to dig, it would be very good to get some indication about which direction to dig in. **BB**'s proposal is similar to an idea described in a semantic web context by Katerina Tzompanaki and Martin Doerr (Tzompanaki & Doerr, 2012A, 2012B).

> *In order to overcome the problem of effective searching* [...] *we propose a querying system for semantic networks based on a few fundamental categories (FCs) and (binary) relationships (FRs). These categories are "base classes" covering the domain, and the relationships are deductions from complex path expressions of all sorts of deep relationships and documentation alternatives in a much richer and more specialized semantic network*[.] (Tzompanaki & Doerr, 2012A)

**BB**'s proposal and the interpretation above point to another pattern, related to but distinct from *Frontend and Backend* – the *Spanning Set*. This may be made up of media objects, or of people. In a standard course model, there is one central node, the teacher, who is largely responsible for all course communication. In OU mathematics courses, this model is scaled up; as **BA** indicated,

> [E]*veryone's allocated a course tutor, who might take on just a half-dozen students – so, they're not the overall person in charge of the course, by any means.* [BA6]

Given sufficient demand, the model could be extended to courses or learning platforms

that are arbitrarily large. For instance, this can be done via a master/apprentice system, in which every apprentice is supervised by a certified master. In the typical online Q&A context, these roles are made distributed, and are better modeled by power laws than by formal gradations.

There are intermediate modes. Stephen Downes is correct that a *star graph* $S_k$ (with $k$ students and 1 teacher) does not work well for learning purposes as $k$ grows.* This is a problem of *Carrying Capacity*. However, a $(j, k)$*-biregular graph*, in which every one of $j$ teachers has $k$ students does not have the same problems if $j$ grows along with $k$. A given discussion group of 100 persons that is divided according to the so-called 90/9/1 rule,† would have 90 lurkers, 9 contributors, and 1 content creator. This is what one might observe, for example, in a classroom with a lecture format. The system would presumably shift if it was broken up into smaller groups. For example, suppose each of the 9 contributors leads a small discussion group of 10 persons. The worst case scenario for at this scale is a "9/0/1 rule" but it seems reasonable to expect "8/1/1" or better.

David Cavallo wrote that in his research with Logo, the goal "*is not only* [working] *for the benefit of others*" but also "*to help the developers themselves formalize and make robust the knowledge required to accomplish the project*" (Cavallo, 2000B, p. 127) This principle can be applied at every level in paragogical projects. It may be embodied by the members (or elements) of a Spanning Set. For instance, it would be worthwhile to make the PlanetMath encyclopedia into an effective Spanning Set for a wide range of mathematics questions. In some cases, a Spanning Set already exists in a concealed form. For instance, the PlanetMath project has an existing *Heartbeat*, in the form of quarterly board meetings and weekly informal discussions. This functions as a Spanning Set for staying up to date in the project's activities – for those who attend. It should be possible to scale up the informal discussions somewhat simply by advertising them more widely; as **RSP** remarked:

> [T]*hings like restarting the community discussions, for example our having our Thursday things once a month, with more people showing up. None of these really require us to build any new software or do anything too time consuming.* [RSP12]

Similarly, "Previews" of features-in-development would help illustrate existing priorities to people who may want to know what's coming next, and how they can get involved.‡ These examples show how in many cases the idea of a Spanning Set can refine the pattern for *Creating a Guide*. Making it clear what people *can* do will help keep them from having to go too far out of their way when it comes time to decide what *to* do.

## Minimum Viable Project

The Minimum Viable Product approach to software development is about putting something out there to see if the customer bites (Ries, 2011). Another approach, related to the pattern just discussed, is to make it clear what people can do with what's there and see if they engage. We might call this the *Minimum Viable Project*, an adjunct to the *Roadmap* pattern, and a new interpretation of the earlier pattern *A Specific Project*.

What makes a project "viable"? Beer (1981) emphasizes the feature of recursivity: viable systems are typically made up of smaller viable systems. This again suggests that one way to strengthen the PlanetMath project as a whole would be to focus on support for individual projects. The front page of the website could be redesigned so that the top-level view of the site is *project focused*. Instead of collecting all of the posts from across the site – or even all of the threads from across the site – the front page could collect succinct summary information on recently active projects, and list the number of active posts in each, after the model of StackExchange questions or Slashdot stories. For instance, each Mathematics Subject Classification could be designated as a "sub-project" and there could be many other cross-cutting or smaller-scale projects. This points to an important syntactic modification to Table 10 [§5.2, p. 74] – introducing the *project* as a container for other productions. Rather than having all of the chains show up in one container, each project would present a distinct context for constructions. Using the grammatical metaphor, relationships between projects would be similar to anaphora as a relationship between sentences.

A viable system is always "*organized with respect to what it is not*" (Deacon, 2014). In other words, each project will have a *Frontend and Backend*. This suggests that projects model their outcomes to some degree of fidelity, and that they are made viable by features that connect to the motivations and ambitions of potential participants. In addition to the basic feature of recursivity, Beer's (1981) dimensions of viable systems (which can be applied to study any project – or pattern) are:

1. **The elements that produce the system.**
2. **Information channels for communication between the elements.**
3. **Internal control/regulation systems.**
4. **Sensors and regulators along the outer boundary.**
5. **Policy decisions governing the system as a whole.**

***Frontend and Backend: A separation of concerns***

**Definition**: The part of the system users see is often connected to a "backend" that they don't interact with as much. Working with the frontend is more formal and rulebound, while working with the backend is relatively informal.

**Problem**: The idea of Frontend and Backend is related to the *Newcomer* pattern: typically one will not expect the user of a system to know how to, or to be motivated to, work with any of the backend features of a system until they have mastered at many of the frontend features. "Users" tend to expect a level of service provision – and *new* users often require some hand-holding.

**Solution**: The pattern of Frontend and Backend lends itself to standard service provision and transactional models of exchange. However, it can also be part of commons based peer production, if people are willing to put in the work. Sophisticated oldtimers can focus energy on supporting individual newcomers by helping them develop a high-quality suite of content and tools focused on their topic of interest. Reflection on this process can inform the development of the system backend. In addition, the new content can help to raise the profile of the site as a whole. This pattern is associated with focusing on *A Specific Project* (following the interests of the newcomers) and with the *Roles* pattern, since it requires a committed and knowledgeable mentor who learn from working with newcomers.

**Challenges**: Simultaneously mentoring newcomers and working on system features constitutes a major commitment. If this work can be spread out among several volunteers – or possibly paid staff – this could have some advantages. Depending on the nature of the process, providing a single point of contact for the user may still be the most straightforward.

**Example**: David Cavallo wrote about an *engine culture* in rural Thailand, in which structurally open systems made tinkering with the "backend" features of internal combustion engines a part of daily life. Cavallo observed that people who were familiar with tinkering with engines tended to be able to learn how to tinker with software, suggesting that there are some common underlying informal reasoning skills.

**What's Next**: At PlanetMath, we have an *open engine*, but not yet an *open engine culture*. Along with continued work to serve and understand specific users by focusing on specific and concrete use cases, we will want to build pathways for meaningful user involvement in work with the software system.

**Table 21:** *The* Frontend and Backend *pattern*

***Spanning Set: Follow the paths in the grass***

**Definition**: With a well-constructed information access system, you may be able to get what you need without digging. If you do need to dig, it is very good to get some indication about which direction to dig in. At the level of content, this may be achieved by using high-level "topic articles" as a narrative map to the content. In general, the Spanning Set may include people as well as less dynamic media objects. A spanning set is comprised of a set of fundamental actions (e.g. asking a question) and fundamental relationships between resources.

**Problem**: People need to know what can be done with a given resource, and this isn't always obvious. Relying on a single knowledgeable guru figure isn't always possible.

**Solution**: A system's features, categories, and relations can be comprised of many different kinds of components, and it needs to be organized in appropriate ways. For example, a "start menu" or pop-up window showing keyboard shortcuts can show what can be done with a given tool; a schedule of office hours can show people when and where they can find help; and topic-level narrative guides to content can show people where to read more.

**Examples**: *Creating a Guide* and *Heartbeat* both produce spanning sets. In a standard course model, there is one central node, the teacher, who is responsible for all teaching and course communication and answering student questions. In large courses, this model is sometimes scaled up through tutors and TAs. In a large MOOC, a "spanning set" of peer tutors could help give everyone personal attention. In Q&A sites, these roles are disaggregated and distributed.

**Challenges**: From the perspective of *Frontend and Backend*, principles and features are visible as part of a system's "frontend" – but the spanning set of relevant behaviors tends to be emergent. If any individual tries to span too much, they will get spread too thin; see *Carrying Capacity*.

**What's Next**: As a project with an encyclopedic component, PlanetMath can be used to span and organize a significantly larger body of existing material. The high-level idea is that of a "cross-index" to the mathematics literature. Initial prototypes should be built for smaller domains (for example, Calculus or Mathematical Biology).

**Table 22:** *The* Spanning Set *pattern*

***Minimum Viable Project: Hard work for no pay? Where do I sign up?***

**Definition**: The Minimum Viable Product approach to software development is about putting something out there to see if the customer bites. Another approach, building on the notion of a *Spanning Set*, is to make it clear to *Newcomers* what they can do with what's there, and see if they engage. Whereas a *Roadmap* lays out a plan for *A Specific Project* that could go nowhere, a Minimum Viable Project is one that people will actually engage with.

**Problem**: Minimum Viable Projects may have a some features in common, and these patterns could be studied using the features of viable systems in general. However, the proof is in the pudding, so we especially need a methodology for trying things out.

**Solution**: The proposal is to take a project-oriented view on everything. Understand actions and artifacts as being embedded within projects, modeling projects in terms of user experience and system features (per *Frontend and Backend*). Where possible, project updates can be modeled with a language of fundamental actions (per *Spanning Set*). Projects themselves model their outcomes to some degree of fidelity, and they are most likely to be viable if they have features that connect to the motivations and ambitions of potential participants. The practical side of this proposed solution will be to build systems that can express all of these aspects of projects, and study what works in practice.

**Challenges**: There are many different kinds of projects, operating at different scales, and with different kinds of actors involved. Each project will have its own *Frontend and Backend*, which will define interfaces to other projects, and this could get complicated.

**What's Next**: The front page of the website could be redesigned so that the top-level view of the site is project focused. That is, instead of collecting all of the posts from across the site – or even all of the threads from across the site – the front page would collect succinct summary information on recently active projects.

**Table 23:** *The* Minimum Viable Project *pattern*

## 9.4 Translating to a pattern-based design

The design dimensions that guided implementation in Chapter 8 can be reassessed in light of this study. Further work on the project can be translated into to a pattern-based design, centered on the three patterns summarized in Tables 21, 22, and 23, where connections to other patterns from Rheingold et al. (2014) are indicated.

Rather than describing the implementation project in terms of (1) *a special-purpose tool customized to suit the challenges of learning mathematics* that would support (2) *an active and interactive process centered on problem solving*, these ideas could instead be described using the idea of a *Spanning Set*. The tool is special purpose just insofar as it makes the actions that are relevant to learning mathematics sufficiently clear. For instance, the notion of a *Spanning Set* could be deployed to progressively clarify the complex notion of problem solving by focusing on the fundamental categories and relationships that make the search for solutions effective. At the heuristic level, a pattern catalog could be used for this purpose, and applied to reassess the implementation.

Rather than focusing on the issue of (3) *motivating users to contribute problems and discuss solutions*, we could instead focus on how users become involved in *A Specific Project*, thinking of these as typically *Minimum Viable Projects*. Minimal, first, in sense that they are often based on relatively small-scale, one-off experiments that will not need to be repeated once the project has run to completion. And second, in the basically microeconomic sense that users will only be attracted to projects which are seen to convey benefits in marginal utility. The issues of "trust" and "credit" that were highlighted in the initial focus group are two small but important facets of what might make a project viable. Users also need examples to follow that show how they can get involved. Question-answering – which comprised a key set of features that were intended to motivate users to contribute problems – addresses primarily informational needs. This sort of feature does little to address interactional needs, which robust support projects would accomplish. Groups on their own do not seem to provide sufficient structure. All of the dimensions of viable systems (Beer, 1981) should be given due consideration in further design and implementation work.

Finally, individual projects – including the software implementation project – can (4) *support mathematical meaning making* – but the details of just how this is supported would be made more clear using the *Frontend and Backend* pattern. In particular, *Frontend and Backend* is directly associated with (5) *support for behavior tracking and semantic modeling*. If PlanetMath users were more easily able to cross between the mathematical and computational ways of thinking, including work with data and analytics (as in Chapter 6), we would be well on our way to building an "open engine culture."

## 9.5 Summary

The layout of Figure 29 is reminiscent of the model of group informatics (Figure 5 [§4.3, p. 55]) from Goggins et al. (2013), but it adds more flexibility to describe the emergent category these earlier authors called "*contextualized interactions*." The approach provides a "meta-model" that looks for emergent order relative to given boundary conditions. As new structure forms, it becomes part of the boundary conditions for future iterations.

Figure 29 explicitly suggests an "open world" model in the sense that projects can be hooked together. The design pattern methodology offers a practical form for a theory of peer learning and peer production in distributed projects. Caroline Wagner (2008) highlights "*emergence*" as one of the key features behind the rise of a "*new invisible college*" among globally networked scientists. The approach seems to be a general and replicable method for doing ongoing emergent design in a peer produced peer learning context.

In the current setting, three design patterns, *Frontend and Backend*, *Spanning Set*, and *Minimum Viable Project* summarize the key take-away from user engagement with PlanetMath/Planetary. In particular, the "What's Next" sections of these patterns suggest practical steps that directly address the main research question [§1.2, p. 5]:

- At PlanetMath, we have an *open engine*, but not yet an *open engine culture*. Along with continued work to serve and understand specific users by focusing on specific and concrete use cases, we will want to build pathways for meaningful user involvement in work with the software system.
- As a project with an encyclopedic component, PlanetMath can be used to span and organize a significantly larger body of existing material. The high-level idea is that of a "cross-index" to the mathematics literature. Initial prototypes should be built for smaller domains (for example, Calculus or Mathematical Biology).
- The front page of the website could be redesigned so that the top-level view of the site is project focused. That is, instead of collecting all of the posts from across the site – or even all of the threads from across the site – the front page would collect succinct summary information on recently active projects.

# 10 Discussion

## 10.1 Recapitulation

I have argued that mathematics is a socially shared, symbolically – and technologically – mediated cultural activity. In light of this, I asked: Could learning mathematics become more like the learning that happens in the course of developing free/open source software? While theories of pedagogy can help us understand conditioning practices, they fail to model the productive, explicating, way in which learning unfolds in online peer production communities, which is described here with a theory of *paragogy*. The paragogy framework I introduced suggested a way to organize and survey prior work in adjacent fields, and formed an organizational tool useful across several scales throughout the work. The core research methodology aimed to build a "thick description" of mathematical social life in the form of a working system for peer produced peer learning. The first study focused on understanding the effects of peer support on learning in the course of encyclopedia authoring activities and forum discussions on the original PlanetMath, documenting the catalysis of learning outcomes. The second study employed qualitative methods to build a richer picture of the stakeholders in a peer learning environment for mathematics, using the paragogy framework to derive directions for change. Informed by this work, PlanetMath's software system was rebuilt along the lines specified by the paragogy model, augmenting the collaborative authoring environment with tools for peer supported problem solving. Qualitative findings from a user study after the public release of the new system demonstrate the feasibility of the paragogical approach, while suggesting a range of improvements to the software that will be needed for the project to successfully scale up – in particular, the further re-structuring of PlanetMath's activities into "sub-projects."

| Context | Feedback | Quality | Structure | Heuristic |
|---|---|---|---|---|
| $A \leftarrow A$<br>$A \overset{\ell}{\leftarrow} A$<br>$X \hookrightarrow \mathbb{X}$ | $X \leftarrow T$<br>$S \leftarrow R$<br>$\mathbb{X} \rightarrow \mathbb{X}^\sharp$ | $X \leftarrow Q$<br>$A \leftarrow C$<br>$X \rightarrow X'$<br>$\mathbb{X} \vDash \mathbb{X}^\star$ | $A \leftarrow P \leftarrow \mathbb{J} \leftarrow S$<br>$L \leftarrow A, P$<br>$M \leftarrow A$<br>$Q \leftarrow A$ | $G \hookleftarrow U$<br>$S \hookleftarrow H$<br>$Q, T \rightharpoonup C, W, P$<br>$G \hookrightarrow \mathbb{E}$ |
| $A$ article<br>$\ell$ link<br>$X$ object | $T$ post<br>$S$ solution<br>$R$ review | $Q$ question<br>$C$ correction | $P$ problem<br>$L$ collection<br>$M$ classification | $G$ group<br>$U$ user<br>$W$ request<br>$H$ heuristic |
| $\mathbb{X}$ project | $\sharp$ update | $'$ fork<br>$\star$ outcome | $\mathbb{J}$ conjecture | $\mathbb{E}$ ephemera |

**Table 24:** *Entity relation diagram for PlanetMath 3.0*

## 10.2 PlanetMath 3.0

Table 24 presents a revised version of Table 10 [§5.2, p. 74], which now includes the insights gained in the user evaluation of PlanetMath/Planetary discussed in Chapter 9. Any object, or activity, that takes place within the system should be thought of as being part of some project. This carries over to the "micro" level, so that individual proof steps or computations are to be thought of as small projects. In particular, one important class of "project" is a conjectural solution to a problem, which can generally be thought of as a (fallible) process for arriving at a solution. In the process of working on problems, groups would like to be able to form on an *ad hoc* basis and create ephemeral content, the online equivalent of a chalkboard that can be wiped clean. Articles – and presumably other forms of project-embedded content – should be forkable. Projects should be updatable, with revised goals or with concrete indications of progress.

Projects can be modeled both in terms of user experience and computational features. Project updates can be modeled with a language of fundamental actions. Projects themselves model their outcomes to some degree of fidelity, and such models provide an interface for other projects and for potential participants. Projects are made "viable" by features that connect to the motivations and ambitions of participants.

Chapter 6 showed results from instrumenting the corrections and forum posts and analysis aggregated data from PlanetMath's contributing population over a decade. It would be useful to instrument the entire system in order to be able to offer real-time feedback on learning relevance of interactions across the system. For example, a sufficiently instrumented system might be able to generate charts of progress on solving specific problems on the fly; *cf.* (Schoenfeld, 1987).

## 10.3 Channels for communication between the strata

As per Hill (2011a), it may be most convincing to market the rebooted PlanetMath project as an effort to build a familiar kind of resource in a new way: for example, to create a free/open clone of a familiar set of textbooks, like the Schuams outline series or the Springer Graduate Texts in Mathematics series, by assembling them out of smaller pieces. Another familiar mode of engagement is the mathematics course. Traditional courses could be run in 1-to-1 (or many-to-1) correspondence with the textbook series mentioned above. One can compare the earlier experiment conducted by Robert Milson, in which he used a local instance of Noösphere to run a graduate-level mathematics course (Milson & Krowne, 2005). However, it would be even more propitious if a course adopted PlanetMath itself as an interdisciplinary "learning project." How might this work? For comparison, consider William Thurston's reflections on "Mathematical education" (Thurston, 1990) and Frank Quinn's perspectives on "A science-of-learning approach to mathematics education" (Quinn, 2011).

For Thurston, an ideal teaching environment was a course on "*Geometry and the Imagination*" that was "*taught as a team, shunning lectures and emphasizing group discussions among students*," culminating in a "*geometry fair*." Quinn's ideal instructional context is "*over a thousand hours of one-on-one diagnostic work with students in the Math Emporium at Virginia Tech*", covering material "*designed so that pre-existing learning errors will cause serious difficulty*," with the intention "*to expose these errors so they can be diagnosed and repaired.*"

Appreciating one of these perspectives need not lead us to abandon the other. After all, "*understanding comes on many different levels*" (Jaffe & Quinn, 1994). PlanetMath may find new purpose in fulfilling the request voiced by Thurston (1990) for "*the creation of channels for communication between the strata*." Surely methods that work – and both Quinn and Thurston have strong points here – should be precisely what is shared and developed through such channels.

One of the participants in the initial focus group I ran at The Open University felt that PlanetMath would be more successful if it was more limited in scope.

> *I think that the planetmath project needs to be sharpened in terms of what it is trying to achieve. That may be done by narrowing down the range of users that it is directed to. Considering the fact that lots of financial resources are spent from formal institutions (like the OU) to develop online platforms for delivering their services, it might be quite hard for planetmath to compete with such platforms.*
>
> Anonymous study participant, excerpt from questionnaire response

It would be useful to sharpen the focus of the PlanetMath project, but not by limiting the range of users it serves, topics it covers, or features it offers.

Rather, PlanetMath needs to maintain a sharp focus on the goal of global mathematical literacy if it is to be successful in establishing effective communication between state school and Ivy League; between first and third world; between researchers, teachers, and students at all levels; and between many individual peer learning projects with a specific local scope. The project as a whole may meet with ambivalence from some parties with deeply embedded institutional commitments; *cf.* (Nietzsche, 1878, pp. 51–52). Even so: "[T]*he emergence of novelty requires that objects be at once both in the old system and in that which arises with the new*" (Mead, 1932).

## 10.4 Teaching mathematics the commons-based peer production way

> *To teach is to honor our commitments by repaying what we owe the world for our formation. In short, teaching (and not ethnographic writing) is the other side of participant observation: there cannot be one without the other, and both are indispensable to the practice of anthropology as an art of inquiry.* ***To teach anthropology is to practise anthropology; to practise anthropology is to teach it****.*
>
> (Ingold, 2013, p. 13), original emphasis

One of the outcomes of the Peeragogy project was a general-purpose framework for building peer learning projects (Corneli, Keune, Lyons, & Danoff, 2013). The Peeragogy project is currently using this syllabus as the basis of a new mutual-aid effort for free/open/peer produced projects called the Peeragogy Accelerator.* This framework can also be instantiated as a syllabus for participation in PlanetMath, as a design for "*active learning*"; *cf.* (Freeman et al., 2014). The idea would be to study mathematics and mathematical anthropology together, and in the process, build and share resources with others. Rather than a classroom culture [§1.3, p. 9], teachers and students who look at mathematics this way would find themselves part of a global culture – but it is one "*without any central committee that would have to, or even could, tell the active what their next operations should be*" (Sloterdijk, 2013, p. 402). This underscores a key refinement to the notion of paragogy introduced in Chapter 3 that has been emphasized in the design coming from Chapter 9, namely the need to focus on individual projects. The model in paragogy is not simply one of unbounded productive emergence, but always an emergence with limits. In regard to productivity, its paradigm is the "*thermodynamic work cycle*" (Kauffman, 2001). This is not made sufficiently clear by the five paragogy principles, which rely on the word "context" and the idea of realized motivation to indicate a sense of scope. The quote from Ingold points to a "*cyclic revolution of continuity*" (Baudrillard, 1976, p. 155). Not only do we now have "*a word for teaching and learning at the same time*" (Kelly, 1994, Chapter 5), but a corresponding set of practices.

*http://commonsabundance.net/groups/peeragogy/

**1. Setting the initial challenge and building a framework for accountability among participants.** Identify a challenge that mathematics or computing could help you solve. How have people approached this sort of problem in the past? What role do technology and media play in previous approaches to this sort of problem? What's at stake now? Share your intention and refine it in discussion with others. Be prepared to go through several rounds of revision as you convert the initial idea into a manageable project. Again, you'll want to consider the way other related projects have been organized.

**2. Other people can support you in achieving your goal and make the work more fun too.** Create a project on PlanetMath and find join a few adjacent or related projects. One place to find of related projects is the list of previews of new features in PlanetMath's issue tracker.* Individual MSC classes can also be considered to be content-related projects. Look around on the internet for other relevant projects. What other problems are people working on that are related to the problem you have identified? Can you collaborate with them? What do you need to learn in order to be helpful in these projects? What help are you likely to need?

**3. Solidifying your work plan and learning strategy together with concrete measures for 'success' can move the project forward significantly.** Find or develop collections or sub-projects that specify the reading material, exercises, and prototypes that will help you move toward your goal. Arrange these into a project roadmap, and revise it as you go. Is anyone interested in your intermediate steps? If you run into difficulties with content or software communicate them to the relevant people. Figure out how you can get take part in resolving the difficulties. If you get stuck, write down and share an antipattern describing the problem, and look for a suitable work-around.

**4. Wrap up the project with a critical assessment of progress and directions for future work.** What did you learn? What roadblocks or bottlenecks did you have to overcome? How will you change your approach when you tackle the next problem? Be sure to upload a project summary with pointers to any new code or content. Assessment is easier if it's ongoing: each of the subprojects you've created should be assessed, and some of them should be wrapped up before the main project is complete. Once you've finished a sufficiently large project, give yourself some time off before you start again on something new.

## 10.5 Limitations

This thesis has been restricted to developing the following three claims.

- A theory of peer produced peer learning was developed, which was given the name paragogy.
- A working model of a paragogical approach to mathematics learning has been developed and deployed as PlanetMath/Planetary.
- A user evaluation of the deployed system has been conducted using principles of emergent design, which has resulted in refinements to both model and theory.

Apart from this clearly circumscribed focus, there are other limitations.

The clearest limitation of this work is that it does not include a classroom study or any other longitudinal analysis of learning under the paragogical model. Accordingly, we cannot say: "prior to the introduction of PlanetMath/Planetary and the paragogical approach, student achievement on such-and-such standardized test was at this level, and now it has shifted on average by Y%." Uptake of the new tools on PlanetMath (Figure 1 [§1.5, p. 12]) has not been sufficient to warrant a study of learning using the methods of Chapter 6. From the point of view of studies of this nature, the work presented here is a necessary preliminary.

Planetary is already used as a course support tool – but evaluating the paragogical model in a mathematics learning context rather than a design context would mean running a course like the one outlined in Section 10.4, and for that, more quite a bit more groundwork is needed. Some form of longitudinal evaluation would be important for developing any policy considerations that might follow from the idea of paragogy.

Although conducting a classroom based evaluation seemed, at times, to be almost within reach, simulation work artificial agents has remained entirely out of scope. Many of the ideas discussed in the thesis may be germane to such studies, but this claim has been in no way tested. This means that even though the thesis points toward a computational model of mathematical collaboration, the usefulness of this model remains conjectural; and its empirical validity stands, for now, only on its own apparent self-consistency.

Inviting PlanetMath users to become familiar with the pattern catalog and write new patterns would have been an interesting opportunity to more fully involve participants in co-design, and to learn more about whether design patterns are indeed suitable for use in the mathematics domain. However, when the studies ran, the pattern catalog was still in a relatively formative state, and would not have been as easy to share or

explain as it is now. My methods evolved along with the research project; *cf.* (Tom, 1996). The Peeragogy community provided a "*structurally parallel situation*" (Cavallo, 2000B, p. 141) in which to develop many of the design ideas. However, the engagement between Peeragogy and PlanetMath and has so far remained mostly "virtual" – and as yet there has been no formal study *evaluating* the pattern methods as employed in either setting.

Spending time working on the Peeragogy project and, earlier, running courses at P2PU, gives a range of experiences to compare with, and, accordingly, helps to make the work theoretically robust. However, exploration comes with costs, and in particular, empirical work trades off against hours spent programming. There were certainly many hours spent on the programming effort, along with many trips to meet with collaborators at Jacobs University. Nevertheless, my initial hope to build actionable semantic domain and user models, as represented by the use case in Figure 3 [§2.3, p. 31] was not realized. Much of the relevant *basic* infrastructure now exists, but recommendations and automatic tutoring have to be left for future work.

Regarding recommendations and diagnostics, the model employed in Chapter 6 has yet to be extensively tested in limiting cases, for example, to ascertain how well it works on small data sets. The model does not yet include confidence intervals. The method would have to be modified further to work in real time as part of a recommendation system. Work with simulated learners would be one route to testing and improving the model, *e.g.* informed by (McCalla & Champaign, 2013).

To ground paragogy as a scientific theory and not just an "approach," it will be necessary to make it falsifiable. This may be most easily achieved by working with a collection of paragogical "micro-theories" presumably based on collections of design patterns (Corneli, 2014), but the precise method for doing the testing is left for future work. Without further development at this level, and without further empirical studies of problem solving, the idea that the work discussed here could add insights into social problem solving beyond those developed, for example, in (Pease & Martin, 2012), remains conjectural – although it does offer a new approach.

To summarize: the primary methods employed in this thesis were statistical analysis of historical data, qualitative field work, implementation of a software system for collaboration, and emergent design. As applied, each of these has certain limitations which might be addressed through further work. However, the greatest limitations of the work might be addressed with methods that were not employed in the thesis, in particular methods coming from artificial intelligence. These were explicitly set aside in order to pursue what I see as groundwork. I genuinely hope that the ideas will be taken forward by others. I outline my own planned contributions below.

## 10.6 Future work

**In computer science:** In order to build a computational study following from this work, one would need: a reasonably large computer-accessible body of mathematical content (perhaps along the lines of my earlier work in mathematical knowledge representation [§2.1, p. 22]), along with computational agents that are able to navigate the relevant mathematical structures (as outlined Table 24), able to apply "standard" (Table 4 [§4.2, p. 53]) and "social" problem solving heuristics (Table 13 [§5.2, p. 79]), sufficiently metacognitively aware [§1.2, p. 9] as to be able to set and solve problems by generating and applying new heuristics in the form of design patterns (Table 11 [§5.2, p. 76]) – and ideally able to annotate, reflect on, diagnose, and extend the overall process (see Appendix F). Appendix B contains two examples that have been worked out in a preliminary manner – but more work is needed in order to fully describe a mathematical proof or exposition as a social-computational processes. To further develop examples of this nature, it would be useful to thoroughly reassess the five dimensions of change described in Chapter 3 – for example, are they really the right ones for dealing with mathematics at the micro level? – and to develop a catalog of design patterns expressly devoted to proofs, problem solving (Posamentier & Schulz, 1996), and problem posing (Brown & Walter, 2004). In particular, the notion of problem posing gets at the essence of pattern-making: we will need patterns about patterns in order to obtain the kind of closure alluded to in the introductory comments on the pattern analysis in Chapter 9 [§9.3, p. 149]. The plan would then be to implement a system that can work with these patterns using a society-of-mind style architecture (Minsky, 1988). Related work using artificial agents in a narrative reasoning context was discussed in (Singh & Minsky, 2005), with a detailed development in (Singh, 2005), drawing on the earlier notion a computational critic (Sussman, 1973). This work emphasized reflexive aspects of mentation and multiple ways to think about problems (Minsky, 2007).

**In humanistic computing:** PlanetMath should at least provide a more satisfactory learning platform for beginning mathematics students than Wikipedia. The idea that peer supported online learning might also be "better" than standard classroom participation, in the sense of Bloom's 2-sigma problem,* does not require a great stretch of the imagination. What it does require is the opportunity to carry out the necessary research.† David Smith (2002) writes that "*learning mathematics is, first of all, learning,*

*Students tutored one-to-one were observed to perform *two standard deviations better* than students who received conventional instruction; Bloom (1984) asks if there are methods of group instruction that can be as effective as individual tutoring.

†As motivation, one can compare results from studies of the JUMP math project from Mary Jane Moreau, and Tracy Solomon et al. (forthcoming); see (Mighton, 2014) and the overview in "A Better Way to Teach Math", David Bornstein, April 18, 2011, The New York Times, HTTP://OPINIONATOR.BLOGS.NYTIMES.COM/2011/04/18/A-BETTER-WAY-TO-TEACH-MATH/

*and only secondarily about mathematics*." It is not necessary to wait for the results of further studies of learning on PlanetMath to pursue related work in other sectors (Corneli et al., 2014).

**Focusing on content:** PlanetMath now hosts, on a demonstration basis, a copy of a recently published free/open textbook on Homotopy Type Theory (Univalent Foundations Program, 2013), and a retrodigitized 20th century calculus book (Davis & Brenke, 1912) both of which have been assembled using interconnected collections.* The sections of these book are discussable, the problems from the book are available to be solved, and some solutions have been added. The contents are presented in MathML, which brings with it the possibility of deep linking and expression-level annotations. The reader's interface could certainly be improved, and integration with Git should be added – after the manner of the deployment of Planetary on MathHub.info (Iancu et al., 2014) and as preferred by the original authors of the HoTT textbook.† And, of course, more books should added as well. Digital libraries are an active area of interest for the mathematics community (National Research Council, 2014). Planetary may prove to be quite useful in this distributed effort, since the system can be straightforwardly adapted to support disparate use cases. Naturally, the recent National Research Council report focuses on research-level applications, but as outlined in Section 10.3, PlanetMath can work on making this effort relevant to stakeholders and constituencies they see as secondary, including "*students below the advanced graduate student level*" and "*researchers outside of mathematics*" (National Research Council, 2014). The National Research Council report expresses disinterest in the large-scale retrodigitization of public domain materials – but, even so, considerable progress could can be made with off-the-shelf OCR tools and small amounts of funding to support a crowdsourcing approach. David Cavallo's focus on finding "*bridges to new content*" (Cavallo, 2000a) is particularly interesting at large scales. Rather than viewing Wikipedia, math.stackexchange.com, and MathOverflow as competitors, they could seen as potential collaborators and contributors to the same commons resource (they all use the same CC-By-SA license as PlanetMath). Perhaps PlanetMath's best application at the moment is not to generate new content, but to focus on organizing and integrating content from these sources and from the public domain.‡

**Hacking the good hack:** Having laid considerable groundwork for the use case outlined in Figure 3 [§2.3, p. 31] both in this thesis and in related work (Mulholland et al., 2013), it is worthwhile to finish the job and add a suitable recommender system to PlanetMath, particularly in connection with the content-focused work outlined above.

# A DIY Math: Course description and post mortem

**COURSE TITLE:**

DIY Math

**COURSE TWEET (200 CHARACTERS OR LESS):**

This course is designed to build independent study and peer-support skills for mathematics learners at all levels. It will require both self-directedness and active participation.

**FACILITATOR:**

Joe Corneli (Board Member at PlanetMath.org; PhD student at the Knowledge Media Institute, The Open University, UK; `HTTP://METAMESO.ORG/~JOE`)

**COURSE DESCRIPTION (NO MORE THAN 500 WORDS):**

This is a mathematics course open to all topics and levels (unless participants come up with a compelling reason to focus during the course). The main "pedagogical" reasons for such radical openness are:

(1) To give people one extra reason to take initiative in their own learning. One might say "I've always wanted to learn about *P* vs *NP*", another might say "I've always wanted to learn precalculus" – both are overcoming a mental and emotional hurdle. I'm not suggesting that it's the *same* hurdle, but there are probably some similarities. In the same way that a writer's workshop can serve writers with different interests, this "DIY Math" workshop can serve mathematics learners with different interests by providing a place to talk about their challenges and successes.

(2) To help people develop skills at co- or peer-to-peer teaching. Ultimately people have to do their own homework exercises and so on, but one can also learn a lot in mathemat-

ics by helping others. My "teaching philosophy" is that there are no stupid questions, even if there are a lot of dumb answers. Let's see if we can get better at answering questions together.

There is no official text book, but participants may want to take a look at "How to solve it" (or other books) by George Polya. Participants will get access to a new "beta" grade libre software platform being developed to support mathematical communication; we'll also have a mailing list available as a fall-back mechanism (and if you're interested in the course, please sign up for the list now to talk about your ideas or any questions you have about the course).

**PREREQUISITES:**

The willingness to learn. Also, you'll need to come up with some realistic goals for a 6-week mathematics course!

**AUDIENCE:**

I hope the participants will want to both *ask* and *answer* questions. Collectively I hope that they will have varied backgrounds and aspirations.

**EXPERIENCE:**

I have a bachelor's degree in mathematics from New College of Florida (2002), and I did a couple years of math grad school before switching to a more "DIY" approach. My current PhD project has to do with "Crowdsourcing a Personal Learning Environment for Mathematics" and this course can be considered to be an informal dry run.

**POST MORTEM:**

Dear DIY Math participants:

I feel like this course is effectively over (and maybe was even "over before it began," though I think none of us saw that). Rather than trying to squeeze more out of the course than it has to offer, I'd like to share my reflections on "what went wrong."

This mailing list, of course, continues to be a place to discuss "DIY Math" in general, and perhaps the course will rise again sometime. I'd like that, and I am not discouraged by what I've learned so far. Further, I wish to salute all of you for your efforts to be self-directed learners. But I think we need a different approach.

The following is my own post-mortem analysis of the course. If you would like to add to it please do. If you feel like the course is not actually over, now would be a good time to speak up about that, too.

My assessment of the course was that participants knew *more or less* what they wanted to focus on, but they didn't exactly know "how" to start, and they didn't particularly want to discuss questions about "how to do things."

Unfortunately, "how questions" were supposed to be the central focus of this *discussion-based* "DIY" course.

At this point, I can see several profound shortcomings in the way I designed the course, not the least being that the implied tension between "doing it yourself" and "discussing it with others" was not given enough attention up front. I had hoped this would be a productive tension or "dialectic," but it doesn't seem to have turned out that way. There is a certain degree of commitment required to work with(in) such a dialectic, and no one who signed up for the course seemed particularly interested in that. Rather, applicants for the most part "just wanted to learn math." I did not do a very good job explaining why I think working with the diy/p2p dialectic is *how* to learn. Moreover, my personal philosophies aside, I simply didn't do enough to get people talking in the course, partly because I rather blindly assumed that the desire to discuss would be shared by all participants. Or, more precisely, I assumed that those who wanted to discuss the most would carry the conversation forward.

Aside from these issues, which I take responsibility for, some of the shortcomings of the course itself point to design considerations that would best apply at a higher level; something like "P2PU best practices." One could say that course-level and P2PU-level issues have some degree of "trade-off" between them.

As one very simple example: If P2PU was taking an ongoing survey of the "wished for" course topics (to be tagged and voted up or down by site visitors), I would presumably have been able to create a mathematics course tailored to the interests of pre-self-selected participants, instead of fashioning a course that was supposed to serve all mathematical interests simultaneously.

As it turned out, I learned at the beginning of the DIY Math course that the interests of the applicants were approximately equally distributed between (1) General interest, e.g. learning how to learn mathematics; (2) Technical interest, e.g mathematics for computer programming; (3) Mainstream mathematics, e.g. precalculus and calculus; and (4) Advanced mathematics, e.g. probability and statistics.

One obvious thing to do "next time" would be to simply run a "standard" mathematics course for each of these four segments. This would be a lot of work to set up, but by no means impossible: perhaps I could find some other people who would want to co-facilitate these courses. My guess is that with significant work and a design that draws on P2PU's collective experience of how to teach (and how *not* to teach) "academic subjects" in a peer-to-peer setting, these courses would all be reasonably successful.

I'll also note that it would be possible to focus on "how questions" in any of these courses (perhaps especially obvious in the case of the first group, since one could copy an existing course on mathematical foundations). Nevertheless, I think the course would most likely need *a lot* more structure in one form or another. There are undoubtedly several different ways to go about structuring something like this, but my guess is that *either* we'd need a more step-by-step curriculum crafted to ease people into thinking about "how they learn," *or else* we'd need to know in advance that participants were really committed to asking and answering "how" questions.

Regarding this issue of "commitment" – which in fact seems quite important independent of the course's "peertagogic" style – in the latest P2PU community call, Alison Jean Cole again reminded me about the idea of setting up a *social contract* for the course.

I said to her that this seemed like another issue that could potentially benefit from support coming from a level above individual courses, e.g. by involving an "course mentor" who would help facilitate the creation of a social contract for the course. This could be someone who had previously run a "successful" course.

Such an idea might go along with re-thinking and nurturing the "social contracts" implicit to the P2PU structure itself (*i.e.* we would ask ourselves what we share as a broader learning community). Some other grassroots organizing styles are very strong on this aspect, both those that are "radicalized" and others that are more politically moderate.

To sum up: I think a course built around "how to learn mathematics" is a great idea. Trying to involve mathematics learners at all levels in discussing this question is also probably a good idea, but a course may not be the best way to have such a discussion. Certainly people need to know what they are getting into in any case.

To conclude: Hopefully we can find the "right" group to make progress on these issues in the future. This course has brought up some of the core problems that apply to peertagogy. We should cut ourselves some slack, because this field is so new that I had to come up with a neologism here and now to describe it! If that's to be a lasting positive outcome of the course, I suppose we should offer a more formal version, "paragogy" (not to be too heavily confused with the etymologically related "paragoge"). Whatever we decide to call it, the key point of DIY Math as a genre is to do away with the artificial distinction between pedagogues and learners. This is a power struggle par excellence, easy enough to mock perhaps, but one I think we should not ignore.

Thank you for your attention,
Joe

# B A paragogy-inspired coding for two mathematical proofs

This appendix applies the paragogy framework to a few short mathematical texts, to help show how the ideas about peer learning developed in the early sections of this thesis relate to the mathematics domain.

As example texts, I've chosen two mathematical proofs where "the obvious thing works", as presented by Timothy Gowers in a recent talk on *Modelling the mathematical discovery process* (Gowers & Ganesalingam, 2012). The detailed small steps presented in this talk give concrete examples of Gowers's notion of the "quantum of progress" as described in Chapter 4. The individual steps are coded as (1), (2), (3), (4), or (5), by matching into this scheme:

| | *Nowak* | *Paragogy* | *Lakatos* | *Peirce* |
|---|---|---|---|---|
| (1) | kin selection | context | concepts | – |
| (2) | direct reciprocity | feedback | examples | induction |
| (3) | indirect reciprocity | quality | conjectures | abduction |
| (4) | spatial selection | structure | proof | deduction |
| (5) | group selection | heuristic | other | – |
| | "social theories" | | "logical theories" | |

This discussion can be connected to the Minskian heuristics for problem solving and the design patterns that were introduced in Chapter 4 and Chapter 5. This leads to the short outline of heuristics for social problem solving, which appears at the end of the appendix. This can be taken as a very preliminary sketch of potential "implementation details" for an agent-based system that would use design patterns to do proofs or tutoring in mathematics.

**To prove: A compact subset of a Hausdorff topological space is closed.**

*First: maybe it isn't so important to know the meaning of the terms.*

[(5) - This is an off-handed remark that is almost certainly not true, but it does suggest an important heuristic: restricting the unknown to whatever it is that we *do* know.]

*Second: This is not true in non-Hausdorff topological spaces.*

[(1) - This looks like an aside, or potentially an extra lemma to prove; however, the purpose it serves in this context is to ensure that we have the *concepts* right.]

*The first step is slightly non-obvious. We'll try to prove that $A^C$ is open.*

[(1), (4) - This is an equivalent definition of the problem statement, however, it's "slightly non-obvious" why this is being used as a proof step. Later in the proof, we'll see why – for an expert who has a feel for the structure of proofs like this, this choice of phrasing is relatively obvious.]

*So, given a point $y \notin A$, we need an $\epsilon$-ball around $y$ that doesn't intersect $A$.*

[(3) - The idea will be to map this hypothetical $y$ to some conjectural but concrete feature, the open ball that doesn't intersect $A$.]

*Take a cue. You have a library of things that can be used in the proof. Use an equivalent statement.*

[(5) - Again, we're reminded to restrict the unknown to what we know.]

*Let $y \notin A$.*

[(2) - This introduces the example we need to operationalize our main conjecture so far.]

*Now expand something else. Because of* **compactness**, *every open cover of A has a finite subcover.*

[(1) - Mechanical expansion of the definition.]

*Finding an* **open cover** *of A would mean finding a collection of sets $\cup$ such that $\forall x \in A \Rightarrow \exists U(x) \in \cup : x \in U(x)$, and U open.*

[(1) - Mechanical expansion of the definition.]

*Because of the* **Hausdorff property**, *$\forall u \neq v$ are such that there are disjoint open sets U and V such that $u \in U$, $v \in V$.*

[(1) - Mechanical expansion of the definition.]

*We now know that "$U(x, y)$" containing $x$ and not $y$ exists because of the Hausdorff property (and because $x \neq y$). Symmetrically for $V(x, y)$. Let $\cup$ be the smallest set of*

$\{U(x,y) \mid x \in A\}$. *Similarly, let* $\mathbb{V} = \{V(x,y) \mid x \in A\}$.

[(3), (2) - We're mapping the hypothetical $y$ to some additional constructs, $\mathbb{U}$ and $\mathbb{V}$, building a more complete model of the space. As part of this complex gesture, the placeholder $x \in A$ is introduced as a example.]

*Let* $\mathbb{F} = \{U(x_1,y), \ldots, U(x_n,y)\}$ *be a finite subcover of* $\mathbb{U}$.

[(4) - We now apply the definition we expanded earlier.]

$w \in A$ *implies* $w \in U(x_i,y)$ *and* $w \notin V(x_i,y)$.

[(4), (2) - Applying previous definitions to move around the unknowns.]

$y \in V \subset \bigcap_{i=1}^{N} V(x_i,y)$. *This would be pulled out of the library.*

[(1), (4) - The fact that finite intersections of open sets are open is a key "concept" that can be applied. We have now positioned the unknown $y$ in an open set that does not intersect $A$. There is also a bit of deduction implied.]

*(All the way through, everything we did was extremely routine.)*

[(5) - This certifies the proof.]

**A 'Magic Leap' problem: compute the 500th digit of** $(\sqrt{2}+\sqrt{3})^{2012}$**.**

*What is the* $500^{th}$ *digit of* $(\sqrt{2}+\sqrt{3})^{2012}$*?*

[(1) - This is just the statement of the problem.]

*Even this, eventually, a computer will be able to solve.*

[(5) - This is an aside, but it points out that there is something here that is non-obvious – *i.e.* an "unknown".]

*For now, notice that total stuckness can make you do desperate things. Furthermore, knowing the origin of the problem suggests good things to try. The fact that it is set as a problem is a huge clue.*

[(3), (1) - We initially guess that we're "totally stuck", but then think more about the context, trying to move beyond the page to see what might be implied. Note that the *social* context is referred to, rather than the *semantic* context.]

*Can we do this for* $(x+y)$*? For e? Rationals with small denominator?*

[(5) - We have now made a critical step, moving from a "known" blob of text to a statement with a useful unknown in it. We can then fill in things that we have some hope of doing calculations about in place of this unknown – for instance, $(1/2)^{2012}$ or $(1/10)^{2012}$.]

*And how about small perturbations of these? Maybe it is close to a rational?*

[(3) - We now begin to form a conjecture.]

*$m^{th}$ digit of $(\sqrt{2}+\sqrt{3})^n$?*

[(2) - Introduce variables as a generalization of the problem statement. (We can't deal with the conjecture directly, so we'll explore.)]

$(\sqrt{2}+\sqrt{3})^2$*?*

[(2) - Try a particular example. We're now exploring the generalization of the problem.]

$(2+2\sqrt{2}\sqrt{3}+3)$

[(4) - Just computation.]

$(\sqrt{2}+\sqrt{3})^2+(\sqrt{3}-\sqrt{2})^2=10$

[(2), (3) - A somewhat clever idea: we've built an example that we can understand. However, this step is also abductive – we may have found a class of expressions that we can understand in a similar way.]

$(\sqrt{2}+\sqrt{3})^{2012}+(\sqrt{3}-\sqrt{2})^{2012}$ *is an integer!*

[(4) - All the terms with odd powers in the second product also have odd exponents on the factor −1, so they cancel with corresponding terms from the first product.]

*And* $(\sqrt{3}-\sqrt{2})^{2012}$ *is a very small number. Maybe the final answer is "9"?*

[(3) - We refine our earlier conjecture.]

*We need to check whether it's small enough.* $(\sqrt{3}-\sqrt{2})^{2012}<(\frac{1}{2})^{2012}=((\frac{1}{2})^4)^{503}=(\frac{1}{16})^{503}<.1^{503}$*, so we're in luck...*

[(4) - This is important to check! (In fact, we could show that $(\sqrt{3}-\sqrt{2})^{2012}$ is still smaller, but it is not infinitely small.)]

*The answer is indeed 9.*

[(5) - We've confirmed that $(\sqrt{2}+\sqrt{3})^{2012}$ is very close to, but just less than, an integer (by the right about)].

The following page collects the key ideas developed above and connects them with Table 4 [§4.2, p. 53] and Table 13 [§5.2, p. 79]. One can also compare the system design overview from Chapter 8 [§8.2, p. 113], which offers a very different but complementary interpretation of what are at their root the same five dimensions.

(1) One of the things that "*experts do*" is *expand the definition.* Experts also have the ability to appropriately "scope" the problem, to explain why it is feasible or important, and to convey some sense of purpose to others. An expert can find the relevant related concepts, establishing the context of the problem. In some cases, technical definitions can simply be "*pulled out of the library*" – but an expert knows which portion of the library to search in.

(2) "*Polling for ideas*" can help generate a set of examples. If you don't know quite what to do, you can try an example to generate ideas by considering a special case or a particular instance of the problem. In this way, in exchange for modest effort, examples offer feedback on the problem solving process. Pacing oneself and cultivating appropriate diversity among instances comprise an important class of heuristics related to example selection. Within a proof, variables can be introduced as examples, which can have either "global" or "local" significance. In some cases, finding even one relatively comprehensible example can suggest a theory that leads to the solution.

(3) Conjecture has to do with outlining a plan, sighting a path, or "*creating a guide.*" Concerning textbook problems, as "*The fact that it is set as a problem is a huge clue.*" Constructions provide analogies, and tentative explanations provide models. These models can subsequently be evaluated on their fitness-for-purpose. Such evaluations allow a problem solver to progressively build and refine an argument. Helpful conjectures are "rewarded" with further attention – non-helpful conjectures (e.g. "*total stuckness*") are abandoned.

(4) "*Changing the description*" of a construct – by symbol swapping and by using suitable definitions – can help shed to light on a problem. A new definition provides a concise "*wrapper*" for an idea or method. Deductions or proof steps are typically meant to be straightforward applications of the definitions. Although the structure of a proof reads "linearly", the way a problem solver finds the right proof steps is often nonlinear.

(5) A "*roadmap*" is a shared strategic plan that is allowed to change. It often comes with rules about the group of agents who are, in fact, allowed to change it. When formulating a proof, we often begin by restricting ourselves to the parts that we know – leaving little archipelagos of the unknown on our map, which can then be divided up and examined. The relevant operations in proofs are not simply about systematically breaking down the unknown, but also include the skillful introduction of unknowns.

# C Selected quotes from initial fieldwork with stakeholders

Sections C1–C5 contain portions of dialog from the initial focus group with computing post-graduates that is described in Chapter 7. Discussants were **M1**, **M2**, and **M3** (self-identified as "more mathematical") and **L1**, **L2**, and **L3** ("less mathematical"). Sections C6–C15 briefly summarize the key features (setting, speaker, etc.) of comments by professionals that inform the later sections of Chapter 7. Primary discussants were Murdoch James Gabbay (**MJG**) and Alison Pease (**AP**). These discussions were not recorded; brief samples from my notes are presented in Appendix E.

## C1 Dialog: Would you find this sort of tool suitable for use in your work or studies?

**M2.** *OK, so, yeah, the first thing that comes to mind is why would somebody would look for something like that? Especially if you assume they're not aware of this PlanetMath website, right. So this should be an ideal first place for someone to go, online, and look for some help. So, in my case, I'm studying, part time, a degree in maths here, at the Open University, and this – it's an online distance lecture thing – and therefor they provide the platform, you can have some kind of interaction with other students and stuff. So, like, the first point of reference, I would, like, go, in case I encounter problems – so, I'm working through the book, I'm trying to understand a method in Calculus, I have a problem, and I don't understand this – so I go to the forum to see if someone else had the very same problem and see if there's an explanation about that problem, and that would be the first thing I do. And if I don't get an answer there, I'll try to post something on that forum, which is already there. So, all I'm trying to say is that the way I open up is also related to the things I know. So, I wouldn't, you know, go online to look for a forum that I don't know, it might take some*

*time also to familiarize myself also with the whole structure and how it works. and, you know, you need, like, when you concentrate, you're trying to understand something, you need to be, like, on a roll.*

**M1.** *But there's one extra point, because if you're having, say, a problem with Calculus, would you trust the forum? So, do the users have a rating in terms of experience?*

**M2.** *Well, you have the – how do you call, it not regulators.*

**L3.** *Moderators.*

**M2.** *Moderators, yeah.*

**M1.** *But, we didn't mention anything about moderators or central control. Because, say, in Wikipedia or in other wikis you have some sort of moderators and central control just to ensure some sort of quality. Or can they just go and define something and then wait for others to say, well, this is wrong?*

**L1.** *Like, I think the discussion about, like, a course forum versus a more general PlanetMath type forum is an interesting thing to think about, um, because what I would think about, again, not from a math background, is kind of, instructor buy in, I think, like, the benefit of you going to your course forum is that your instructor is there, and your classmates are there, and you're using the same texts. And, again, I'm not knowledgeable about math, but, say if I were to plug in something about long division, there are different ways of teaching and learning long division, so I guess – the "pro" of going to something within the course is that you'll be taught, and you'll know, you'll have similar parameters or similar methodology. And whereas with PlanetMath, I think if I were going there as someone who is a total math newbie, it would almost overwhelming to parse the type of information.*

## C2 Dialog: Describe your learning style

**L3.** *If I approach this thing from, I want to increase my mathematics skills, I don't exactly know where I am, because I stopped doing school courses 10 years ago, so I've gained some and I've lost some. I'm interested in this, and that, and generally very interested, maybe not in this, but this – but I don't search specifically for a topic, but just something that will get me further. And getting me further sort of implies that it's at my skill level, so that I can understand the text. So that requires a little bit of searching around, probably looking at different things. What really would would help me is trust, again, trust in the fact that if I don't understand something, or I'm stuck, it's my own fault, it's not due to an error in the problem or article. So that's where I would start, and then, presumably it would be nice to have something like a map or a histogram or a list or a chart of the area – the charted area, or the uncharted.* [...]

**L3.** *What is it like, you get a question, the square root of 3 for example, and then you answer it – if the question's more complex, what does the answering look like, do you sort of go away, and do your scribblings on some paper, and you find the answer and you post it in, or is it more like, is the problem solving, progressive, in steps?* [...]

**L3.** *So I think that for people like* **L2** *and me who like to do prototyping, and do iterative solutions, and approximate a solution* [...]

## C3 Dialog: How do you currently solve problems?

**M3.** *It's not practical for logic, but when you do some programming, you have to parse some text, you would look if someone else had solved it and use their solution, just to save some time.*

**M2.** *I think what's important is the immediacy of trying to solve it. You're there, you're concentrating. You don't want to lose this concentration, get familiar with a website, that would totally destroy my concentration. The first thing I would do is stick with it.* [...] *And it could be, like, an exercise that you are trying to solve for the assignment that you have to submit, and you wake up with the solution in your mind. So that's one way of solving the problem. Then, you might need to go to the forum and see if someone else had the same problem and – sometimes there are students who have the same problem, and there are a lot of students and they reply and they get it right. Or maybe the moderator comes in the end and says this is how it works and maybe you want to look at that.*

**M1.** *It depends on what you're using the forum for – I use both strategies depending on the problem. Sometimes you just get a generic error message and it's not really clear and you just have the message on that. So you go to Google and you find dozens of posts on forums that will give you the solution almost instantly. But sometimes if you're trying to develop something that's a bit complex, that's not the problem, you're just developing it and it takes time. And you need to just work at it.*

**L1.** *To me it depends a little bit on where I am on in my own lifecycle of research. Like, when I'm starting out, and I'm doing more general thinking like – again, this is not a math example, but say like which theorists I need and are kind of essential for foundational knowledge – I think what I would do to solve that problem is different from what would do when I'm deep into my topic, and I then I do more, kind of, introspective problem solving, or I'll email a former trusted adviser, who I know kind of shares my orientation – I think I refer more to personal sources when I'm more deep in it, versus when I'm doing more general, then I'll turn to forums or do Google search. I think it depends a little on stage of problem solving. Or, maybe, also the kind of sophistication of problem solving.*

**L2.** *Yeah, I also think that it depends on the topic.* [...] *Motivation is important. Looking*

*at examples – then again, it depends on the person, it's quite general.*

**L1.** *It always depends on the type of problem that you run into – is it a boring problem that I just want to get out of the way, is it a personally interesting one, and you want to play with it.* [...] *Do I expect to get something out of it, or do I just want to get it out of the way?* [...] *There are also formulated problems that come to you in a formulated way, like an error message for example, or problems that you have to first formulate. And also, old problems that people have had before, or new problems that nobody has had before.*

## C4 Dialog: Describe your learning style (continued)

**L2.** *To me, with the learning style, I like the learning by doing, and I have to say, with maths, usually there is this problem, that usually they teach without getting hands on, and for people who learn by doing, sometimes that's kind of an issue.*

**L3.** *How important would you say immediate feedback is?*

**L2.** *Yeah, visualizations, or...*

**M3.** *Can I just say one thing about learning styles? I think it's not just important for you to know everything, but it's very important to know how to find things when you need – I think that's more important, rather than trying to understand everything. I mean, in general. I think the skill would be nice – you cannot kind of capture, understand everything in all domains, it's too ambitious.*

**L2.** *The platform, also, in this case can play a role, right, of making it easy for you to find problems.* [...]

**L3.** [When compared with workbook style problems] *that's a way more interesting problem, of how do you scaffold complex problem solving. I mean, one easy approach would be "making aware of possible approaches" – can you break the problem down into subproblems, can you do a sort of root-cause analysis (I don't know if that's used in maths, but other areas certainly). Just probing the... prompting the user with different ways to think about the problem, if it's not trivial.* [...] *Can you use substitution? Made me think about, can you build an ontology of problems, make an estimate of the size of problems in terms of the number of steps usually required.*

## C5 Dialog: How do you deal with people whose viewpoints are very different from yours?

**M2.** *I was thinking about the learning styles – yeah – what kind of learning? You have opportunities to learn different things in different situations, right. And normally you learn something after you have defined certain aims. So in my case, I want to understand the*

*mathematical theory behind the computational model I'm using, and therefor I decided I have to build the mathematical background. And how am I going to do that? I'm going to build it from from scratch. So, you know, I defined my aim, how am I going to learn something. And that's one way to do it, I'm going to follow it, I'm just doing it there. You have other aims, like, sometimes, you realize, oh my god, you're having a conversation, and you realize... like, this guy learns this way, and I'm not really doing this. Like, for example with* **L3** *yesterday, he was – we were having a discussion, and he was telling me, you interact with other people and this is how you learn. And if I think of myself, and me doing the PhD, over the past how many, 3 years, I haven't really done this to, um, a similar extent that* **L3** *does it, I mean,* **L3** *does this as a practice – I mean, I'm interacting with my supervisors, and I have this kind of thing, but you have much more opportunities to get out there to see how people learn, and bla bla bla. So, that also gets at the other thing, which is, how do you deal with people whose viewpoints are very different from yours? So, I think the different viewpoints has to do with the aims that people have in mind. They, basically, they use a certain kind of learning that they have identified as a proper one, in terms of getting somewhere, that, there is an aim behind it. And therefor, you see, OK, these people have different aims and different learning styles for achieving these aims...*

**M1**. *Yeah, sorry, it might also be a misconception so, hence, sometimes it's a different viewpoint because it's just a different point...*

**M2**. *OK, yeah, yeah, how, with regard to a particular...*

**M1**. *Problem let's say, and they would like to solve the problem this way, but they've got to conform to the standards.*

## C6 Comments on online mathematics

"*It would be useful to have better systems for giving and receiving feedback.*"

**MJG**, comments after my talk presented to the Mathematical Reasoning Group at the University of Edinburgh, and reemphasized in our interview at Heriot-Watt. **MJG** told a story about how he had tried to learn about ultrafilters from various sources around the web, some that were very incomplete, and some that included outright mistakes. Generally, these sources do not come with easy ways to comment.

## C7 Comments on encyclopedia articles

"*Highly-abstracted and non-expository articles are hard to understand: they suffer of impenetrable quasi-formality.*"

**MJG**, discussing ultrafilters (Figure 11 [§7.3, p. 97]), *etc.*, in our interview.

## C8 Comments on student attitudes toward peer learning

"*Students are not comfortable sharing their work with other students. They are only somewhat comfortable showing it to their professor, whom they regard as one might a medical doctor.*"

**MJG**, commenting on his experiences with "peer pedagogies" in our interview.

## C9 Comments on computational tools for mathematicians

"*Formalisms are only useful when the model can't be held in your head.*"

**MJG**, in the discussion following my talk at University of Edinburgh.

## C10 Comparison of PlanetMath and Wikipedia as reference resources

"*Wikipedia seems to have better coverage, better exposition, and a nicer-looking interface.*"

**MJG**, discussion in our interview, based on a side-by-side comparison of the two websites.

## C11 Alison's description of her approach to research

"*Empirical studies of mathematical discourse are a key research focus.*"

**AP**, first interview, describing her approach to research. Further details appear in Table 15 [§7.4, p. 100].

## C12 Alison's description of her approach to research (continued)

"*How does experience build towards understanding?*"

**AP**, first interview, discussing themes in her research.

## C13 Tools that could be useful for studying mathematical discourse

"*It would be useful to be able to detect the first use of a word within a given episode of discourse, and to measure it's impact.*"

**AP**, second interview, looking at how PlanetMath could be directly helpful in her research.

## C14 Comments on computational tools for mathematicians

"*Can we build more detailed models of mathematical discourse?*"

Informal discussion with Mohan Ganesalingam and Sir Timothy Gowers, of Cambridge University, visitors to the Mathematical Reasoning Group at University of Edinburgh, who spoke with me about linguistic modeling of the mathematics domain, and interactive software.

## C15 Comments on artificial intelligence for mathematics

"*Even if computer mathematics did a good job of simulating human mathematics, it won't do things the same way humans do.*"

**AP**, first interview, reflecting on the joint work of Gowers and Ganesalingam (Gowers & Ganesalingam, 2012).

# D Selected quotes from interviews with participants in the user evaluation

This appendix presents a selection of illustrative quotes from interviews with participants in the field trial described in Chapter 9. These quotes are referred in brackets in the main text: for instance, [AC3] references the third quote from subject **AC**. Table 20 [§9.1, p. 142] presented a brief description of the interview subjects; the key data is repeated below. Recordings from **AA** and **AB** are missing due to a problem with the recording software; accordingly, data from these interviews is embedded in diagrammatic form in my handwritten notes, and not included below. **BC** dropped out of the study before completing an interview.

## AC Selected quotes

German resident, male, mathematics PhD, staff scientist and programmer, long-time PlanetMath user (contacted through PlanetMath).

1. *But these are escape things, is there any documentation. . . because they're not necessarily LaTeX stuffs.*

2. *Yeah, that's great, when you can use everything that's available in LaTeX with PlanetMath, I think that's really positive, because you can't do that with other places, with Wikipedia, you can't build such things.* [. . . ] *Because, I'm thinking, if I'm blogging Wordpress, and if I'm doing it, I have to convert everything I've written in LaTeX in Wordpress, and that's a lot of work.*

3. *And, recently you know, I was looking at the activity in PlanetMath, in the past 5 days, since I posted something new, there wasn't much activity in PlanetMath itself.*

4. *But, the funny thing is, I mean, assuming that somebody wrote an article like 10 years ago, what would happen then? He's, like, not anymore active in PlanetMath.*

5. *Another question is – regarding the problems – if I post a problem, can I watch on it? Because I haven't seen this possibility. Let me try again, I cannot remember, but that was one of the issues that was lingering in my mind. Alright, yeah I'm not able to watch* [...] *Oh, no no, I am - "you're not watching this" - so, I'm able to watch, so maybe that's my mistake.*

6. *Well, I was really seriously thinking of putting some really you know... but these are articles, I do not know the validity of them or something... so I can put them in articles... I can put them... I'm not sure if I should put them in problems or so, so I was just a bit confused – I'm not sure where they should land.* [...] *Well, I mean, they are, like you say, open problems... you can put it in problems, right – but suppose you are working on an open problem, and you have certain theories, and you're not really sure if these theories are at all correct. And you just want to put stuffs.*

7. *Every time I have some such issues, I won't hesitate, I'll just bombard you with screen-shots or questions. I know you're quite busy with these things, but it might help. Do you have a bug tracker?* (I tell him that the project is developed on Github, and we use the integrated bug tracker there.) *Oh really! Is it, I mean, do people look at it, I mean, some bug trackers they're just...*

8. *I think what StackOverflow, or, I mean I think it's called MathOverflow, there's also this Math-StackOverflow something, it's fine, but it's not too personalized. With PlanetMath, you can log in, and then you can, maybe you can, it's easier to find, or to categorize or to organize your problems there than in StackOverflow.*

9. *Yeah, I think it's more user friendly when it comes to users having problems with their homework or asking question. For instance, there's this MathOverflow, they filter out, they only entertain people who are a bit of, above graduate level, but in PlanetMath you don't have this problem, I mean this you don't have this kind of...*

10. *Well, you know, for instance I'm doing some private research, mathematical research, purely mathematical, that has no application at all, you know, it just interests me. I was thinking, you know, I could write a blog on it, because I'm not really interested in having publications, because, the problem I see with publications, is that you have to wait for... almost a decade until all the reviewers suddenly say, OK, this is fine and then you can publish it. I mean, I've had experience with it in my Ph. D. years, that you know you'll have to wait a long time because the reviewers don't really have time for it; and then after that, you will have to do the changes that the reviewer asks you, and then after that, it's published. But I would prefer to have it already online,*

*I'm really not interested in having my work officially published, because in the end, the people who are getting benefit from are actually the press, and it's not really the scientists who are involved, because in the end, people have to buy my articles, which is not interesting for me. So I was interested in writing blogs about this thing. But now that PlanetMath comes to... you know, I was thinking of, maybe it would be possible to do such, write my researches in PlanetMath.*

11. *I think the problem is PlanetMath lacks some of the most trivial things, like, for instance, if I posted something, like about Lie algebra or something, then after one month, I do not see it in my history. Unless it's an article. If I post it in, like as a question, or in a problem set or something... I never see it in my history and if I search for it, it's a catastrophe. You cannot – you're not able to search it.* (I show him the "Score" tab.) *... but this includes also the things that I've viewed.*[*]

## BA Selected quotes

UK resident, male, engineering background, enrolled in the Open University's mathematics masters program (contacted through OU mathematics department).

1. *Um, right, I started out with an article* [...] *I did find, however, that when I was typing into it, I was pressing "preview" to see what it looked like, but it would have been really convenient to see what it looked like in some ways, as I went along. But, it wasn't clear – I ended up doing a lot of "save" operations and then carrying on, because I wasn't clear as to whether the thing was going to time out on me, and then all the data would be wiped – because, it's quite a slow process, obviously – if I had left it a few hours, and then went back, and wanted to make some amendments to it, because I couldn't actually see the article, you know, you had to sort of go in, make your amendment, do a preview...*

2. *Um, yeah, because there are so many categories, I found it a bit confusing. Yeah, so, something like "collection", I would think that ought to be something where you would have an editor, who would move articles around, into collections, say, rather than a writer choosing which collection to be in.*

3. *Yes, it's a – it's a different approach really. So, I mean, something – probably something like a collection – it would probably be good if an editor could at least move something, collect articles together, perhaps place some blank articles there – you know, to try to get someone to actually write one.*

[*]More detail was added to user pages after this interview.

4. *Yeah, I mean, that's another thing – you might have a collection, where you have something at, say, at school level, and another one at, I don't know, postgraduate level. And there really isn't going to be any overlap at all.*

5. [E]*veryone's allocated a course tutor, who might take on just a half-dozen students – so, they're not the overall person in charge of the course, by any means.* [...] *It is called Elluminate, spelt with an E, I think it's some Canadian organization; it's got lots of Java in it, but um, it's essentially a whiteboard, with very limited ways in which people can talk, apart from the tutor.* [...] *In OU terms, the forums, essentially, there's a moderator, and they try to dispel any talk about these Tutor Assignments, at all, on these forums.* [...] *Well, you – either* [solve the problems] *yourself – or if you're in difficulty, you should contact your tutor. Well, they're quite helpful, in that they'll give you a hint to set you off in the right direction. And, obviously, if all else fails, these questions are normally in parts, so if you can't do one part, you can just move on to the next. So that is not, if you like, exclude you because you've sort of... failed to get enough marks on your assignment.*

6. *This one, I dropped before the end, and that was Functional Analysis, it was just too, if you like, abstract for me.* [...] *I think that Functional Analysis is just, if you like, it's really something that is so abstract – that, it would be very d... – I think there are some people who can find their way around that, but, for some people, you reach a certain level of abstractness, and they're just lost.* [...] *Well, as it turns out, my current course - does use a few of the ideas of functional analysis, in the sense that you get finite dimensional linear spaces, rather than infinite dimensional spaces... which you can't really visualize, you can't draw pictures, really... so, I mean, I find that quite straightforward; I mean, it's really just ordinary vector spaces, things like that, which is sort of undergraduate stuff.*

## BB Selected quotes

UK resident, female, engineering and software background, enrolled in the Open University's mathematics masters program (contacted through OU mathematics department).

1. *Because, I mean, what we've got on PlanetMath is masses of very good math, masses of very good theorems and results and definitions and so on; I just found it a bit difficult to find the one I wanted.*

2. *But is a problem – are you thinking of a problem as something that a teacher has provided for a student to look at, and he has the answer that the student can then go and look at, when he's tackled the problem?* [...] *Because if I was in there thinking*

*about answering someone else's question, I want to know, whether that's just a person who wants to know how to do something that I can easily tell them, or whether the tutor has put up something for them to do, and we're not supposed to be answering it, they're supposed to be finding it out for themselves.*

3. *I think it would also be nice to have a place to talk with mathematicians, without thinking that you might be making a permanent copy on the website, that ought to be correct and validated and so on, so that you can say, how about this for an answer... where you might be guessing just as much as the other person... but the forums don't seem to be very much used.* [...] *I don't have any problem with them being public, it's that I want it to be quite clear that I'm just speculating, and not giving a definitive proof or theorem or whatever, because most of the site is definitive material.*

4. *So, you would expect if somebody asked a question, that the person answering it wouldn't answer the question, they would just point them in the direction of how to think about it.*

5. *Well, I certainly go into all the OU forums. I certainly ask questions and answer questions. And actually, answering questions is just as much learning as asking them. Because you have to spot how the person who's asking it is looking at something from a funny angle, or upside down, and then explain the way you should be looking at it.* [...] *But don't you just find it interesting, the way other people approach problems? It gives you a whole new view on the world, to see some other, other, um, attitude to the same question that you've just taken for granted – suddenly you get a new perspective.*

6. *I read a section of my maths text, sometimes trying to understand the proofs of the theorems, but more often just reading and trusting that they really work. Then I try to work through some examples or exercises. This often brings up questions about the original material. For example, I ask myself, "Why does the closed contour theorem talk about a function having a primitive while Cauchy's theorem requires an analytic function? What is the significance of this difference?" I think that it is only when I begin to join up bits of the theory in this way that I am really learning.*

7. *I think it's more, the problem is, that when you go out to look at a particular theorem or whatever, you can't very easy get back, you might do your back button, but you might have to do 10, 12 presses to get back to where you started from – whereas if you could have a collection or a topic article or something in your breadcrumbs at the top, then when you'd been wandering around following leads, you could then jump back to where you were.* [...] *I don't think it would need the whole history, I think it would just need the thing that was the topic, whether that's a collection or a topic*

*article, a sort of high level thing, that when you went into one, it would remember that until you went into a different one at the high level. It would be a bit difficult to have everything listed where you'd been, all the way, like a history, it would be too complex.*

8. *I think they're just a bit difficult to find, which is why I was just suggesting that maybe topics should be brought up to a higher level, and listed separately from articles. So that you can easily find a whole topic, and then like you say that topic gives you the introduction into all the bits that belong to it – probably work better than collections, because being basically an article, you can have all the links, and you can have the words in-between.*

9. *Yeah, also, maybe we could have these sections in smaller steps. You might be able say, I'm looking for a theorem, or I'm looking for a definition, or I'm looking for a method.*

## RSP Selected quotes

US resident, male, physics PhD, long-time PlanetMath user and active volunteer (Raymond S. Puzio, requested non-anonymity).

1. *I should mention, with the 3C's and your elaborations – I figured last night that I should explain to you what I meant, because there's been some confusion. So, you are absolutely right about the importance of the code and the organization, however, I guess the way I'm thinking of it is that those two are more, sort of, in the background, they're what's supporting it. Whereas, what I'm thinking is that the content, the catalog, and the community is what the typical user will be interacting with.* [...] *So, that's what I meant, so the idea is, if they're interacting with the 3, hopefully some of them will get interested in looking in the background.*

2. *Also, as I found when I was rummaging through the Library of Congress catalog last week, there's oodles and oodles of elementary math books of problems out there in the public domain – I'm sure we have... we might even have a million problems if we managed to get all of those in.*

3. *Some people might find the shared document and email enough, others might want a voice channel, others might want something else, maybe they want, let's say some algebra program that's running, and a common place to save files.*

4. [A]*s for other uses I'd like, interacting with people on PlanetMath – a lot of that is going to depend on building the user community, for example if I have an interest*

*in a research-level topic, there's someone with a similar interest to talk about it with there.*

5. *Personally, ok, that information would be good to display, but you also have to involve people, because let's say they posted a lot, but they might be too busy, or might not be in the mood to talk about it – so I would say that improving the interaction along with that would be important.*

6. *So I guess one way of thinking of it is as a replacement of our bio – I mean our user home pages. My idea would be to replace those home pages with some such more robust thing.*

7. *Not just make it easier to respond at your own pace, but also to put that information in a useful form, like here's people's interests, here's the ones who already know you and are contacting you, and ones you might want to contact, etc.*

8. *One thing about content could making it specific. Let's say, we look at* [elided]. *OK, then the community might be, currently the community might be* [**AB**] *and myself and one or two other people. Content, OK, we've got her catalog – her collection – of* [elided]. *Catalog end, I could just extract from the Library of Congress all the books pertinent to that subject. Even if we don't have time to build everything up. So, even if we don't have time to build everything up, at least we could build up that one sub-project really nicely.*

9. *Well, let me tell you* [...] *two specific instances. One thing I did was, we had this project with Matte and Cameron, where we had this project, where the there of us were looking at the counter-examples in topology, and just making sure they were all on PlanetMath. Another one was when – that you probably know – was when Matte tried to do his thing with the real number project, which was basically such a role, the problem was that at that time, it seems he didn't have resources or the support he needed, and he got frustrated.*

10. *So, what I'm thinking is* [...] *I'm not so worried about automating. In the past, I've served that purpose of bridging users together. And I could see myself doing it again, it's just that, for doing that, I should free enough time to make sure I actually have time to interact with people.* (Pause) *So you know, for example, in the past, I've started things like this project we had with topology, and other things, and you know, brought people in. So, one hope I've had is that I'd have an hour or two a day to working on the community side and exactly helping people with such things.*

11. *OK, let's say, Internet Archive, sooner or later, they're going to have them all uploaded as graphics images, if we have the OCR running, then, yeah they could all become*

*TEX files, but it might be that only a handful of those ever gets human edited into proper editions, because only they get enough attention.*

12. [T]*hings like restarting the community discussions, for example our having our Thursday things once a month, with more people showing up. None of these really require us to build any new software or do anything too time consuming.*

# E Illustrative excerpts from field notes

**(Day 2 of field work) Did any of your hypotheses get corroborated as a result of your data analysis? If so, which, why and how strongly?** I got some good insight into "peer supported problem solving" from the point of view of a mathematics researcher and instructor. With his "instructor hat" on – what he wants is for his 100 students to *talk* with each other. But he wants this because he wants them to turn in better papers. He doesn't care if they work together or whatever! He just wants them to learn the stuff better. He seems, in this regard, to be a really amazing instructor. So, we came up with a model that might work. ("Paper mock up" - I'll have to think more about whether I could implement the thing he needs in software.) With his "research hat" on, we saw that expository text is very different from what might be called "quasi-formal" mathematics – and PlanetMath has a lot of the latter. With things like this, you don't see what the point is. One definition points you to another. I used to write a lot like that. It's interesting to think about how this could be improved (either on PlanetMath or Wikipedia, which, on average, is better in this regard already).

**(Day 3 of field work) Did any of your hypotheses get corroborated as a result of your data analysis? If so, which, why and how strongly?** "How could PlanetMath help with that?" was an ongoing question. In some cases the answer was very "hypothetical" but in general there tended to be an answer. For instance, looking at some of the rather "bad" (in Jamie's view) articles through the linguistics of mathematics view of Mohan, I can see how PlanetMath might integrate a tool that could *show* how "formal" a given article is, and help lead authors to present their work with suitable expository details. Some of this I could likely do even more cheaply, without waiting for Mohan's work to be completed.

# F A critical apparatus, applied to developer discussions

> [I]*t is by headlong flight that things progress and signs proliferate.*
>
> (Deleuze & Guattari, 1980, p. 73)

Table 25 collects the themes from Chapter 9 [§9.2, pp. 143-148], and expands them using key points from the literature review conducted in Chapter 4 (Figure 6 [§4.8, p. 66]). The issues identified in Chapter 7 (summarized as α–ο in Table 16 [§7.5, p. 104]) appear as further annotations. This shows that many of ideas from the initial work with potential stakeholders were still points for discussion in the user evaluation, underscoring their importance, while showing that the underlying issues are not fully resolved.

The mapping here confirms the relevance, for PlanetMath users, of some of the notions coming from the literature. For example, in Chapter 7, it was observed that (λ) "*Users want to be able to make adaptations that leave traces, and simple customizations that don't.*" This is connected to McCalla's idea of "*gradual localized accumulation of information.*" Observing that (ο) "*Computer understanding and formal theories of quality and effective social heuristics are good long-term goals*" connects with McCalla's idea about "*supporting purpose-based use*" illustrates that there is quite a bit of work needed to understand the pragmatic purposes that are involved in mathematical activities.

Chapter 7 gathered ideas about user feedback (β) and involving users in technical work (κ) that had not been encountered in the literature review. There is of course a healthy literature on end-user programming and contributions to free/open source software. This material is relevant to a paragogical approach, but it is easy to see why it did not come up in Chapter 4, given the aims stated there [§4.1, p. 48]. This does suggest the need for caution in applications of the paragogy framework.

To be successful, system developers must find ways to mesh what happens on the site with participants' phenomenal experiences of mathematics.

- human language
- sensory perception
- logic and deduction
- intuition, association, and metaphor
- stimulus/response
- process and time
- socialization [ν]
- content
- community [η]
- catalog [η]
- organization
- software [ι]

There will be a boost in participation and learning-relevant measures if users can express their ideas easily in written language.

Improved graphics and interactive features will also boost participation and learning-relevant measures. [μ]

"Projects" should be modeled as progressive problem solving. [δ]

- personal attention
- public statements
- argumentation and rationale
- shared understanding
- collaborative knowledge
- cultural artifacts
- personal comprehension

The process of progressive, informal, problem solving maps onto the history of interactions and curatorial activities. [γ, ζ]

Roles can regulate behavior in the project, but most roles are ephemeral. Collections based on use tracking can help users create more concrete roles.

- gradual localized accumulation of information [λ]
- focused on the end user
- supporting purpose-based use [ο]

When compared with "closed" production, "open" production comes with a host of new problems to solve.

relevance quality [α] scalability consistency motivation [α]

Users need feedback and follow through: consistency is important in social interactions, not just for expository content. [β, κ]

Concrete applications are an indicator of quality. [ε, ξ]

People will be willing to put in effort if it helps them build "literacies" that they can use to reliably achieve their informal goals.

- getting information
- giving information
- reputation building
- relationship development [θ]
- recreation
- self-discovery
- constructive feedback

**Table 25:** *A critical apparatus, with mnemonics*

The idea is not that the heuristic concepts in Table 25 should be "*corrected and improved until at last they are worthy of a place in the list of fundamentals*" (Bateson, 1972, p. 5). Rather, much in the same way in which the "grammar" in Table 24 [§10.2, p. 160] could be used to parse mathematical activities, Table 25 can be used as part of a working language that describes the "para-mathematical" activities that are involved in building and improving PlanetMath. Something like this seems necessary if mathematics is to once again be seen as "*a living science*."* In principle, this apparatus can be applied to connect the problems that still exist in the working prototype with the research literature, and the research and development programme. Like the Peeragogy pattern language, this apparatus should be used as a distributed *Roadmap*, or rather, a set of roadsigns. As with the *Roadmap* pattern, it should be regularly revised.

 A similar lexicon should be developed to code the expository features of mathematical text. The "dangerous bend" sign from Bourbaki is a prototype.

**Application: coding developer discussions** This apparatus is applied here to code eleven outstanding but high-priority issues selected from the Planetary Github tracker. This coding seems particularly suitable for application at the per-ticket level, although it could potentially be used at fine-grained levels to directly annotate text. This helps to connect the theoretical work developed in the thesis with the everyday concerns of developers, and helps to check the completeness of the apparatus.

The dynamics of developer interactions were not studied in detail in the thesis, but the data is online for curious readers, for example: Issue #87 is a prime example of social problem solving. Issue #106 is managed by one person, with updates posted in a blog-like manner. After an initial information-gathering phase, Issue #351 is still open, although preliminary work, on Issue #68, is completed in a branch.† These tickets also help to illustrate my role within the Planetary project, as both "designer" and "software integrator" (I *opened* 332 out of 383, or 87%, of the total issues) as well as programmer (I closed 162, or 78%, of the *closed* issues). The full set of tickets is online,‡ along with additional summary information on developer participation in the Planetary project.§

*Early volumes in Springer's Graduate Texts in Mathematics series include this note in the backmatter: "*A student approaching mathematical research is often discouraged by the sheer volume of the literature and the long history of the subject, even when the actual problems are readily understandable. Graduate Texts in Mathematics, is intended to bridge the gap between passive study and creative understanding; it offers introductions on a suitably advanced level to areas of current research. These introductions are neither complete surveys, nor brief accounts of the latest results only. They are textbooks carefully designed as teaching aids; the purpose of the authors is, in every case, to highlight the characteristic features of the theory. Graduate Texts in Mathematics can serve as the basis for advanced courses. They can either be the main or subsidiary sources for seminars, and they can be used for private study. Their guiding principle is to convince the student that mathematics is a living science.*"

†https://github.com/m-iancu/planetary

‡https://github.com/KWARC/planetary/issues

§https://github.com/KWARC/planetary/contributors

#407 editor needs to be supplemented with a “cheat sheet”

The editor could be made much easier to use, with a cheat sheet and more buttons.

#381 SQLite instead of MySQL

It would be good if contributing developers could get started with an instant deployment, and SQLite would be one way to help with this.

#354 Planetary should do better error reporting for LaTeXML fatal errors (was: silent failure of DruTeXML/LaTeXML for posts containing an unescaped “# symbol”)

It’s very confusing for usrs if they don’t get feedback on errors in source code they submit. Other services, like ShareLaTeX, do a relatively nice job with this, with line-level markup to indicate errors.

#351 killer feature: use git to facilitate instant revisions

With suitable integration, Git could be used within Planetary in order to get the best of both Noösphere-style ownership and wiki-style editing. The work done on the MathHub frontend does not support this sort of feature yet.

#328 Meta-ticket for module cleaning process

To help future developers, the source code needs a lot of refactoring. Drupal has a “submodule” feature that can be used to organize things.

#288 make the user experience faster for contributing authors

Currently, users have to wait for processing which would be better to do in the background.

#88 developer docs

Documentation that will help people who are interested in development work have a good experience may help to bring in more volunteers.

#73 deal with subpath for image conversions (was: send in basepath as LaTeXML flag)

Links/Backlinks between gallery pages and the documents that use the images are not currently available.

#68 SVN/git integration

Even without fancy UI features and awareness of the ownership model, Git could be used directly for storing revisions. This is done in the MathHub branch of Planetary.

#67 build system

🗐, 💾 If LaTeXML changes or if there is some other reason we need to rebuild all of the content, we currently do this with a script, but this does not give feedback on which articles or macros are breaking. There is a separate LaTeXML build system, but this is not integrated with Planetary.

#46 integrate JOBAD into planetary

🔎, 🐞 JOBAD is a Javascript package that has been used on a demonstration basis to build intuitive point-and-click in-document interactions (like per-line corrections and comments).

**Abstract**

A preliminary treatment of a social creativity is presented that aims to be "mechanism independent" in the sense that it could equally well describe the behavior of simulated societies of computational agents or the embodied behavior of humans engaging in commons-based peer production. The idea of project-embedded problem solving is used as a connection between these two domains. Mathematical thinking provides an inspiring example, and the methodology that is proposed is an interpretation of the highly heterodox interdisciplinary theory of design patterns.

# 1 Introduction

From the perspective of creativity, licenses are a blunt instrument. Copyleft licenses (CC-By-SA, GNU GPL, etc.), non-copyleft licenses (CC-By, MIT, etc.), copyright waivers (CC-Zero), and the public domain support a vibrant culture of creative reappropriation. However, if the taxonomy of licenses is understood as our native theory of "free culture," then it seems we are collectively turning a blind eye to the all-important *creativity* that makes it all work. One thing that's not made particularly clear in the legal approach is that creative work has a lifecycle: at minimum, a beginning, middle, and an end. We need to pay more attention to understanding the intricacies of the "middle bit." In short, despite their important role as protectionary measures, licenses are not of great help in explaining or directly facilitating the genesis of cultural works.

Similarly, (general) economic behaviors, like gift exchange, potlach, or division of labor, can contribute incentives, norms, or boosts to efficiency, but they are typically second-order phenomena, since they assume that there is something there to exchange or destroy, or that there is a process to subdivide and enact. Of course, creativity very often develops at the social, symbolic, or economic level, but this is all the more reason not to take these phenomena as fundamental *explicata* for creative culture. In addition, as Shaw and Hill [20] make clear, the particular economic form known as commons-based peer production is in no way a political or social panacea. On the one hand, "*many successful peer production projects exhibit strong inequalities of participation and deeply entrenched leadership*" – on the other, many free/open software projects never attract collaborators at all. As researcher and free software activist B. Mako Hill argued earlier, "*The benefits of collaboration become something to understand, support, and work towards, rather than something to take for granted*" [11].

This paper approaches that challenge by trying to understand creativity in a mechanism independent way. The hypothesis that computers can simulate humans is not directly useful for building a theoretical model of creativity. What is more interesting is a social-computational perspective that says that certain combinations of humans and computers can simulate relatively advanced computer systems. For example, from the point of view of any given user, a peer produced website might be said to roughly approximate an artificial intelligence with an agent-based architecture. Similarly, the history of mathematics might be thought of "as if" it were an analogous long-running computational process, carried out mostly on paper. The fact that mathematics actually developed in the minds of humans is, clearly, not to be neglected. Nevertheless, the complementary fact that mathematics can be communicated between humans means that it can exist, to some extent, *in charta* or *in silica*. Mathematical creativity can accordingly be thought about in a way which sets aside the question of whether it is carried out by humans, societies, or computers, and which focuses, instead, on the fundamental features of mathematical form. These typically include definitions, theorems, and proofs along with explanations, remarks, questions, and so forth. Mathematics is by no means the only domain that can be studied in this way. Mathematics is, rather, an inspiring and well-studied example, and one can point to practical advances in fields like automated theorem proving that are associated with a computational approach. This example helps to motivate the mechanism independent study of the social-computational dynamics that are involved in the creation of software and other cultural works.

## 2 Building a mechanism independent model of creativity

**Embodiment and sociality are the antidote to "as if" thinking for humans and computers.** Tim Ingold [12] makes a distinction between "as if" thinking conducted, for example, by expert systems, and in-the-world thinking carried out by humans. In addition to their crafty minds, one thing that individual humans definitely have, which computers generally do not, is a robust embodiment. Ingold classifies writing in the same "as if" category as expert systems, since written expression tends to be equally disembodied. Manual DeLanda [7] (from whom I've borrowed the idea of "mechanism independence") talks about a potential antidote to "as if" thinking in computer systems: if we can give the computer even a limited embodiment, putting it in touch with a virtual world – then it doesn't have to have everything worked out in advance. In the case of mathematical thinking, individual humans are in contact with a rich phenomenal world, in which they find themselves capable of drawing lines in sand or on slate, discourse with other humans, and visualization or embodied feeling-ones-way through complex mental projections. A minimum mechanism independent model of creativity should include *agents* and *phenomena*. In particular, agents exist simultaneously as part of one another's phenomenal world, and this is referred to as *sociality*.

**Agents relate around works and acts.** Works, skills, acts, and agents themselves can all be created. Property and ownership are some of the rules that govern the relationship of agents to works, and these rules can become arbitrarily complex. Thus, for example, CC-By-SA-NC says "You can do (almost) whatever you would like with this work – as long as you give me credit, share any derivative works under the same license – and don't sell them." However, one ought not assume that creativity itself takes place exclusively in the context of one big commons, for instance, a given license "pool" like that defined by CC-By-SA-NC. Rather, creativity takes place within working groups, families, homesteads, etc., and it may be understood to evolve within nested contexts at several scales. For instance, creative work done within a given kin group might be comprehensible by other members of their linguistic community, and may be shared at the level of expression within a cultural commons, even if the work itself remains the property of its creators [13]. Even works that are shared more broadly tend to be created, enjoyed, and reproduced in smaller local contexts. In his public talks, Creative Commons cofounder Lawrence Lessig often quotes the composer John Phillip Sousa: "*When I was a boy... in front of every house in the summer evenings you would find young people together singing the songs of the day or the old songs.*"

**Mathematical thinking: decompose processes into theories and problem solving projects.** Quite a bit of background knowledge typically goes into stating, formulating, understanding or proving any given theorem. To speak metaphorically, the relevant definitions and lemmas are something like a neural substrate, in which the new theorem is expressed as a thought. Individual proofs can be broken down into subtrees and formal proof steps, but mathematical insight is better studied from the informal perspective of problem solving heuristics. One classic heuristic is to look for simpler versions of a hard problem and to try to solve those. Relevant social heuristics include asking for help. At any given point in a mathematical thought process, there may be many problem solving projects taking place on different levels: for example, one may be simultaneously carrying a digit, factoring a polynomial, finding a root, and designing a mechanical structure. A given mathematical theory or culture will suggest relevant approaches. In general there can be multiple agents, goals, and approaches at work.

**The more general case: emergent design patterns.** If mathematics is the formal theory of patterns, it can be quite useful to compare it to a relatively *informal* heterodox theory of patterns coming from the field of design. First introduced by the architect Christopher Alexander [1, 3], the design pattern methodology spread from architecture to software [9], and later, to other fields, including public affairs [19] and education [4]. Alexander's patterns are presented in a tree-like structure called a *pattern language*, ordered in a top-down manner from large-scale to small-scale levels of application, with each pattern presented in terms of a *picture*, a *context* (including links to relevant larger patterns), the *problem* that the pattern addresses, the *solution*, a *diagram*, and *links to smaller patterns* [3, pp. x-xi]. A relatively convincing implementation of Alexander's idea of patterns as a "*living language*" [3, p. xvii] was realized with one of the earliest applications of wiki software developed by Ward Cunningham: the Portland Pattern Repository.[1] Taking the idea of a pattern language as a point of departure, the *Peeragogy Handbook* [18] includes a catalog of patterns for peer production and peer learning that the authors discovered while working on the book. The patterns are presented using a template that is closely aligned to the

[1] `http://c2.com/ppr/`

structure coming from Alexander (Table 1). Each pattern is essentially a short textual abstract, describing an active dimension of the Peeragogy project. This emphasis on the active aspect is made particularly clear through the "What's Next" facet, which concretely links the patterns in the *Handbook* to the current activities being conducted within the aegis of the Peeragogy project. Connecting the patterns to the project in this way helps to convey their "living" nature, and the pattern catalog evolves together with the project. The notion of pattern-finding as a process related to, but distinct from abstraction, is described by Richard Gabriel, who emphasizes that the "*patterns and the social process for applying them are designed to produce organic order through piecemeal growth*" [9, p. 31]. In its original form, this statement describes the generative use of patterns to create artifacts (buildings, object oriented programs, etc.). However, this criterion is applied here to the growth and development the pattern language itself.

**Title**: Encapsulate the idea – possibly include a subtitle.

**Definition**: Explain the idea and the context in which it is meaningful.

**Problem**: Explain why there's some issue to address here.

**Solution**: Talk about an idea about how to address the issue.

**Challenges**: Talk about what can go wrong.

**What's Next**: Talk about specific next steps.

*Illustrations, and the following, are optional:*

[**Objectives**: Explain the purpose(s) of the proposed solution's functioning, if not fully specified by the description of the solution itself.]

[**Examples**: Present example(s) that have been encountered, if this aids comprehension.]

[**References**: Citations, if relevant.]

Table 1: Pattern template from the *Peeragogy Handbook*

**Example: emergent design for peer learning.** Patterns offer a heuristic but nonetheless relatively rigorous way to do ongoing "emergent" design. Some of the central patterns described in the *Peeragogy Handbook* indicate that peer learning projects often organize around a temporal *Heartbeat* of meetings, divide the work among several *Roles*, and have to decide what, and whether, to *Use or make* (often remixing earlier works). We've observed that even with a high-level *Roadmap* in mind, participants tend to drift until they pick *A Specific Project* and get down to work. With these and other patterns in mind, the analyst has a simple language for talking about what works and what doesn't work in the online peer learning context. The process of analysis is rigorous in the sense that either an existing pattern matches the topics under discussion, or new patterns should emerge. For example, in [6], the Peeragogy pattern language was applied to study user feedback about a new system that was developed for the mathematics website PlanetMath.org, resulting in three new patterns (*Minimum Viable Project*, *Frontend and Backend*, and *Spanning Set*) that expanded on or clarified earlier patterns. Each of these has its own "What's Next" within the context of a specific project.[2] The *Peeragogy Handbook* collects a dozen patterns and a half-dozen antipatterns (using the same template but emphasizing "Challenges") composed after the fashion described here. As an initial set of patterns describing peer production and peer learning, this catalog forms a candidate description of a creativity commons (Table 2, with details at `http://peeragogy.org/practice`). There are hundreds of other patterns that have been written over the years, but generally without the project-embedded focus adopted here – which puts this work in comparatively direct contact with phenomenal experience.

[2]For illustrative purposes, the *Spanning Set* pattern is reproduced in Table 3 in the Annex to this article.

*Patterns*

**Wrapper** – Front end appearance to participants. Consolidate and summarize.

**Discerning a pattern** – Found a pattern? Give it a title and record an example. (Woah, meta!)

**Polling for ideas** – Invite brainstorming, collecting ideas, questions, and solutions.

**Creating a guide** – Overviews expose the lay of the land. Collecting content and stories.

**Newcomer** – Welcoming "beginner's mind."

**Roadmap** – Plans for future work, direction towards a goal, dynamic.

**Roles** – Specialize and mix it up. Play to participants strengths and skills.

**A Specific Project** – Lightbulb moment: Most specific projects involve learning!

**Carrying capacity** – Know your limits, find ways to get other people involved.

**Heartbeat** – The "heartbeat" of the group keeps energy flowing.

**Moderation** – When leaders step back, dynamics can improve; moderator serves as champion and editor.

**Use or make?** – Repurposing, tinkering, or creating from scratch?

*Anti-patterns*

**Isolation** - A tale of silos, holes, and not-invented-here.

**Magical thinking** – "One meeting will (not) change everything!"

**Messy with Lurkers** – What happens when joining is low-cost and completion is low-benefit.

**Misunderstanding Power** – The workload is almost never evenly distributed.

**Navel Gazing** – "I have this really great idea…"

**Stasis** – What drives collaborative projects? (Whatever it is, it doesn't always work.)

**Stuck at the level of weak ties** – Can we deepen the connection?

Table 2: Catalog of patterns from the *Peeragogy Handbook*

## 3 Outlook and next steps

**Heuristic methods.** As Alexander [2] indicates, it will be a challenge for software developers, architects, and others – educators and researchers for example – who are inspired by the design pattern methodology to work together to transform the lived environment. An especial challenge is to find a way to work across different fields and different levels of analysis, "*integrating different types of theories and concepts in such a way that one can formulate meaningful propositions embodying findings now sequestered in separate fields of study*" [10, p. 44]. Although it makes certain epistemological and ontological assumptions that may not be appropriate in every conceivable case (regarding, in particular, the possibility of a "problematic" understanding of reality) – the adapted design pattern methodology described here should nevertheless be widely applicable as an informal dialectical method; cf. [8, p. 203]. The Peeragogy project will continue to develop its catalog of design patterns in practice based on active participation, with a new quarterly peer produced development course beginning in June, 2014, featuring rolling enrollment.[3] Participants will be invited to develop new candidate patterns starting from a simple reporting protocol (adapted from [23]):

> *(1) Review what was supposed to happen. (2) Establish what is happening. (3) Determine what's right and wrong with what we are doing. (4) What did we learn or change? (5) What else should we change going forward?*

**Computational methods.** Keeping in mind the core aim of mechanism independence, a parallel research agenda involves implementing a computational system that can work with design patterns using a society-of-mind style architecture [14]. Although design patterns have been used extensively to guide programming, there are still many challenges associated with moving from an informal heuristic modeling approach to a formal computational model. Related work using artificial agents in a narrative reasoning context was discussed in [22], with a detailed development in [21]. This work emphasized reflexive aspects of mentation and multiple ways to think about problems [15]. The orientation described here suggests a more cultural and less psychological tack. For instance, microtheories may be useful for describing local cultural contexts, and this resonates with the Ostrom-inspired view on the commons [17]. Another key question to examine is the way different local contexts link together. Nowak takes an evolutionary game theory approach to this question [16]. Here, one would rather consider hybrid cultures and blended theories: and the prospect for referring this work to ongoing research on *computational blending* looks good. Mathematics continues to be a motivating example, and the first order of business will be to develop an extension of the pattern catalog oriented to *mathematical* creativity.

## 4 Conclusion

As a collection of design patterns focused on peer learning and peer production projects, the Peeragogy pattern catalog can begin to be used right now as a heuristic theory of social creativity. It is simultaneously rigorous and anti-fragile: individual patterns need to be negotiated and reasoned through relative to the existing catalog, while the catalog as a whole will improve with discussion and debate. As a system connected to practice within the Peeragogy project, the pattern catalog is very much subject to change and further development. The individual "What's Next" steps serve as a distributed *Roadmap* for the Peeragogy project – and as the work done in the context of PlanetMath shows, they may be useful as a "living language" spread across several peer production sites. Although the computational system described above remains projected and conjectural, the design sketch usefully expands on an earlier discussion of multi-agent architectures for computational creativity, hinted at in [5]. This earlier article focused on critical assessments of creative progress. Here, creative progress is viewed as connected to formulating and working on problems, or, rather more profoundly, asking how a society "*is able to pose the problems set within it and to it by the differential relations it incarnates*" [8, p. 235]. The problem posed here, in a necessarily preliminary manner, asks how we can understand peer production in a computational way.

## 5 Acknowledgements

This work has been supported through EC funding for the project COINVENT 611553 by FP7. I would like to thank Helene Finidori for helpful conversations.

# Annex

***Spanning Set: Follow the paths in the grass***

**Definition**: With a well-constructed information access system, you may be able to get what you need without digging. If you do need to dig, it is very good to get some indication about which direction to dig in. At the level of content, this may be achieved by using high-level "topic articles" as a narrative map to the content. In general, the Spanning Set may include people as well as less dynamic media objects. In general, a spanning set is comprised of a set of fundamental actions (e.g. asking a question) and fundamental relationships between resources. In the case of media objects, it may reduce to the pattern *Creating a Guide*, but the guide may need to be updated regularly to remain relevant.

**Problem**: People need to know what can be done with a given resource, and this isn't always obvious. Relying on a single knowledgeable guru figure isn't always possible.

**Solution**: A spanning set of a system's features, categories, and relations can be comprised of many different kinds of components: for example, a "start menu" or pop-up window showing keyboard shortcuts that shows what can be done with a given tool; a schedule of office hours so that people know how to find help; and topic-level narrative guides to content.

**Examples**: One social version of a Spanning Set is the classical master/apprentice system, in which every apprentice is supervised by a certified master. In a standard course model, there is one central node, the teacher, who is responsible for all teaching and course communication and answering student questions. In large courses, this model is sometimes scaled up through tutors and TAs. In a large MOOC, a "spanning set" of peer tutors could help give everyone personal attention. In Q&A sites, these roles are fully disaggregated and distributed.

**Challenges**: From the perspective of *Frontend and Backend*, principles and features are visible as part of a system's "frontend" – but the actual spanning set of relevant behaviors tends to be emergent. If any individual tries to span too much, they will get spread too thin; see *Carrying Capacity*.

**What's Next**: As a project with an encyclopedic component, PlanetMath can be used to span and organize a significantly larger body of existing material. We have come up with a high-level design for a "cross-index" to the mathematics literature. We're working on a prototype for Calculus.

Table 3: The *Spanning Set* pattern

# PEERAGOGY IN ACTION

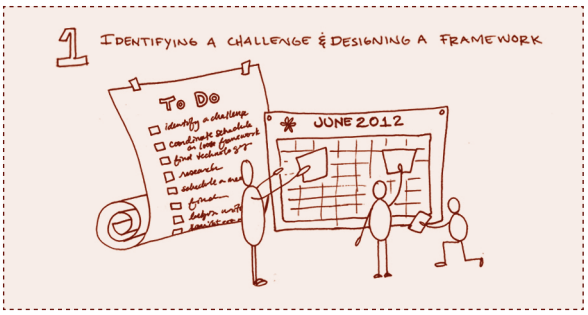
by *Joseph Corneli, Charles Danoff, Anna Keune*
and *Amanda Lyons*

*Peer-produced Learning*

We have been writing the missing manual for peer-produced peer learning: the "Peeragogy Handbook" (peeragogy.org). Throughout this work we have asked and aimed to address questions like these: What would a motivated group of self-learners need to know to agree on a subject or skill to learn, find and qualify the best learning resources about that topic, then select and use appropriate communication media to learn it together? What would these people need to know about learning to put together a successful learning programme?

*It is clear to us that the techniques of 'peer production' that have built and continue to improve Wikipedia and GNU/Linux have yet to fully demonstrate their power in education.* We believe that the Peeragogy Handbook can help change that by building a distributed community of peer learners/educators, and a strongly vetted collection of best practices. Our project complements others' work on sites like Wikiversity and P2PU, and builds upon understandings that have developed informally in distributed communities of hobbyists and professionals, as well as in (and beyond) the classrooms of generations of passionate educators.

Here, we present Peeragogy in Action, a project guide in 4 parts. Each part relates to one or more sections of our handbook, and suggests activities to try while you explore peer learning. These activities are designed for flexible use by distributed groups, collaborating via a light-weight infrastructure. Participants may be educators, community organisers, designers, hackers, students, seasoned peeragogues, or first timers. The guide should be useful for groups who want to build a strong collaboration, as well as to facilitators or theorists who want to hone their approach. Together, we will use our various talents to build effective methods and models for peer produced peer learning. Let's get started!



**Part 1: Identifying a Challenge and Designing a Framework**

Setting the initial challenge and building a framework for accountability among participants is an important starting point.

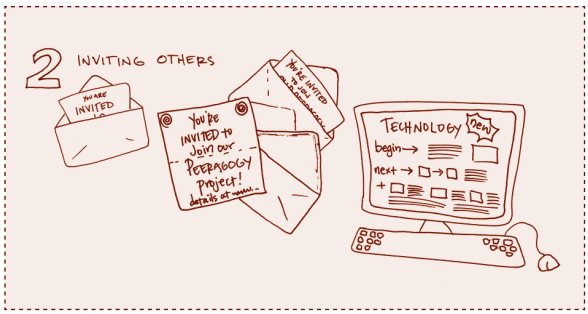
- Activity—Come up with a plan for your work and a 'contract' for your group. You can use the suggestions in this guide as a starting point, but your first task is to revise the plan to suit your needs. Helpful questions can be: what are you interested in learning? What will your main outcome be? What problem do you hope to solve? What steps do you need to take to accomplish this? How collaborative does your project need to be? What sort of support do you anticipate needing personally? What problems won't you solve?
- Technology—Familiarise yourself with the collaboration tools you intend to use (e.g. Wordpress, Git and LaTeX, YouTube, GIMP, a public wiki, a private forum, or something else) and create a first post, edit, or video introducing yourself and your project(s) to others in the worldwide peeragogy community.
- Suggested resources—The Peeragogy Handbook, parts I ('Introduction') and II ('Peer Learning'). You may also want to work through a short lesson called 'Implementing Paragogy', from the early days before the Peeragogy project was convened (https://en.wikiversity.org/wiki/User:Arided/ImplementingParagogy). For a succinct theoretical treatment, please refer to our literature review, which we have adapted into a Wikipedia page (http://en.wikipedia.org/wiki/Peer_learning).

-----➤ Further reading—Boud, D. and Lee, A. (2005). 'Peer learning' as pedagogic discourse for research education. Studies in Higher Education, 30(5):501-516.

-----➤ Observations from the Peeragogy project—We had a fairly weak structure at the outset, which yielded mixed results. One participant said: "I definitely think I do better when presented with a framework or scaffold to use for participation or content development." Yet the same person wrote with enthusiasm about models of entrepreneurship: "freed of the requirement or need for an entrepreneurial visionary." In short, there are trade-offs to be made—hopefully in an informed fashion.

**Part 2: Inviting Others**

Other people can support you in achieving your goal and make the work more fun too.



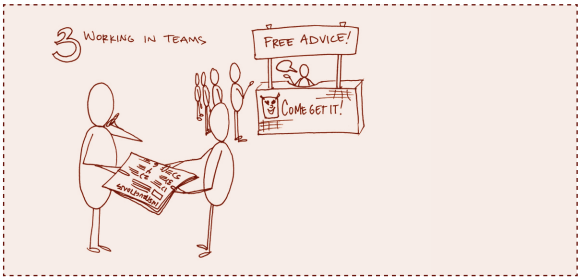
-----➤ Activity—Write an invitation to someone who can help with your project. Clarify what you hope to learn from them and what your project has to offer. Helpful questions to consider: What resources are available or missing? What do you already have that you can build on? How will you find the necessary resources? Who else is interested in these kinds of challenges?

-----➤ Technology—Pick a tool that's new to you and could potentially be useful during the project. Start learning how to use it. Locate some people around the world who share similar interests.

-----➤ Suggested resources—The Peeragogy Handbook, parts III

('Convening a Group') and IV ('Organizing a Learning Context').

- Recommended reading—Schmidt, J. Philipp. (2009). Commons-Based Peer Production and education. Free Culture Research Workshop Harvard University, 23 October 2009.
- Observations from the Peeragogy project—We used a strategy of 'open enrolment': new people were welcome to join the project at any time. We also encouraged people to either stay involved or leave—several times over the past year, we required people to explicitly reaffirm interest in order to stay registered in the forum and mailing list. This choice cut down on 'dead weight'. Nevertheless, the project continued to accumulate content, which gave newcomers the discouraging feeling that there was a lot to catch up on. We've aimed to sum up the high points in the handbook!

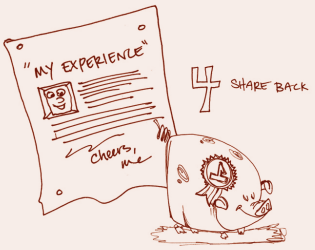


**Part 3: Working in Teams**

Solidifying your work plan and learning strategy together with concrete measures for 'success' can move the project forward significantly. Working in teams and sharing information with others will help you to develop your project.

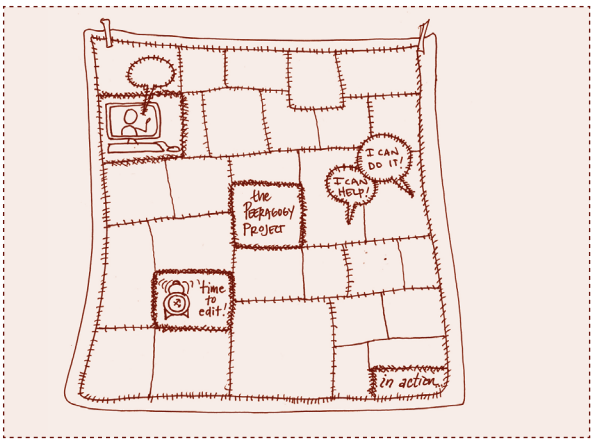
- Activity—Concretise your ideas by, for example, writing an essay, making visual sketches, or creating a short video to communicate the unique plans for organisation and evaluation that your group will use. Then, edit the pages of the Peeragogy Handbook boldly: by this time you should have identified at

least one section that needs to be improved. Make the necessary revisions.



- Technology—Take time to mentor others or be mentored by someone, meeting up in person or online. Pair up with someone else and share knowledge together about one or more tools. You can discuss some of the difficulties that you've encountered, or teach a beginner some tricks.
- Suggested resources—The Peeragogy Handbook, parts V ('Co-Facilitation and Co-Working'), VI ('Assessment'), and part VII ('Patterns, Use cases, and Examples').
- Recommended reading—Argyris, Chris. "Teaching smart people how to learn." Harvard Business Review 69.3 (1991); and, Gersick, Connie J.G. "Time and transition in work teams: Toward a new model of group development." Academy of Management Journal 31.1 (1988): 9-41.
- Observations from the Peeragogy project—Perhaps one of the most important roles in the Peeragogy project was the role of the 'Wrapper', who prepared and circulated weekly summaries of forum activity. This helped people stay informed about what was happening in the project even if they didn't have time to read the forums. We've also found that small groups of people who arrange their own meetings are often the most productive.

**Part 4: Share Back**



Wrap up the project with a critical assessment of progress and directions for future work. Share any changes to this syllabus that you think would be useful for future peeragogues!

- Activity—Identify the main obstacles you encountered. What are some goals you were not able to accomplish yet? Did you foresee these challenges at the outset? How did this project resemble or differ from others you've worked on? How would you do things differently in future projects? What would you like to tackle next?
- Writing—Communicate your reflection case. Prepare a short written (or video, or photo, ...) essay, dealing with your experiences in this course. Share the results by posting it where others in the broader Peeragogy project can find it.
- 'Extra credit'—Contribute back to one of the other organisations or projects that helped you on this peeragogical journey. Think about what you have to offer. Is it a bug fix, a constructive critique, pictures, translation help, PR, wiki-gnoming or making a cake? Make it something special, and people will remember you and thank you for it.
- Suggested resources—The Peeragogy Handbook, parts VIII ('Technologies, Services, and Platforms') and IX ('Resources').
- Recommended reading—Stallman, Richard. "Why software should be free." http://www.gnu.org/philosophy/shouldbefree.html (1992).
- Observations from the Peeragogy project—When we were deciding how to license our work, various Creative Commons licences were proposed (CC Zero, CC By-SA and CC By-SA-NC). After a brief discussion, no one was in favour of restricting downstream users, so we decided to use CC0. In connection with this discussion, we agreed that we would work on ways to explicitly build 'reusability' into the handbook content.

**Micro-Case Study: The Peeragogy Project, Year 1**

Since its conception in early 2012, the Peeragogy Project has collected over 3700 comments in our discussion forum, and over 200 pages of expository text in the handbook. It has given contributors a new way of thinking about things together. However, the project has not had the levels of engagement that should be possible, given the technology available and the global interest in improving education. We hope that the handbook and this accompanying syllabus will provide a seed for a new phase of learning, with many new contributors and new ideas drawn from real-life applications.

## Abstract
Wiki-like or crowdsourcing models of collaboration can provide a number of benefits to academic work. These techniques may engage expertise from different disciplines, and potentially increase productivity. This paper presents a model of massively distributed collaborative authorship of academic papers. This model, developed by a collective of thirty authors, identifies key tools and techniques that would be necessary or useful to the writing process. The process of collaboratively writing this paper was used to discover, negotiate, and document issues in massively authored scholarship. Our work provides the first extensive discussion of the experiential aspects of large-scale collaborative research.

## Author Keywords
Collaboration, writing, crowdsourcing, scholarship.

## ACM Classification Keywords
H5.m. Information interfaces and presentation (e.g., HCI): Miscellaneous.

## General Terms
Human Factors, Management.

## Introduction
The way people collaborate continues to evolve rapidly with technology [21]. Many of the challenges that researchers in fields such as HCI face require

interdisciplinary input and collaboration [12]. In this paper, we argue that wiki-like and crowdsourced [7] models of collaboration can provide currently unrealized value to academic writing and research. We propose that such a model of engaging many people from different disciplines through short-time-scale cycles of collaboration can enable research and provide insights that go beyond what is feasible with the small-group model that is prevalent today.

Many massively multi-authored academic papers already exist, both as targeted experiments, such as the Polymath Project [9], and as the result of large-scale collaborations in particular disciplines, such as Venter et al.'s "The Sequence of the Human Genome" [23] (with contributions from approximately 2900 co-authors). However, these papers do not discuss the experiential aspects of such collaborations.

The current paper was written in a distributed fashion by thirty authors, with approximately ten additional people contributing in some way but ultimately opting not to be listed as authors. At the onset, the only aspects of the paper that were specified were the topic of the paper, the target venue (with format and deadline constraints), and a few principles about collaboration. Writing the paper provided the research context, and the final paper emerged as a research artifact. We have sought to engage in a conscious reflection on the authorial process, and to identify possibilities and challenges that arise at the juncture of academic research, distributed authorship, and digital technology.

The goals of this paper are twofold. The first goal is to discuss the methodology and tools that enable an *ad hoc* group of academic researchers and other interested individuals to gather, work together and produce a scientific paper collaboratively. Working together with a large number of authors, we must take into account the preferences and ideas of a broad cross-section of researchers, a process known to be challenging [10, 19]. The second goal is to experiment with this type of collaboration, including empirically identifying and validating best practices, and present reflections on the process.

Our work provides the first extensive discussion of the *experiential* aspects of large-scale collaborative research. Our findings were established via a research-through-writing approach in line with earlier discussions of research-through-design [26]. This work is of value to CHI practitioners seeking to design tools and environments for large-scale collaboration on scientific research and writing, by revealing the opportunities and complexities of this process.

## Related work

Collaborative writing has been around since well before digital computation, but contemporary projects such as Wikipedia and Crowdforge [13], have demonstrated that crowdsourcing could be used to create written content of broad scope and high quality.

Although work on the social aspects of *coordination in collaborative writing* in the Wikipedia context [24] particularly informed the analysis we give in this paper, we see many differences between writing for a general audience without deadlines, and writing a peer-reviewed submission with deadlines. These differences suggest different interaction designs. The closest empirical paper of which we are aware examined the

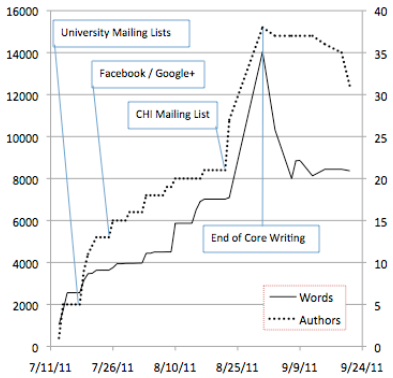

**Figure 1:** The change in word count and number of authors over time. Significant events in the recruiting of authors are noted in callout boxes.

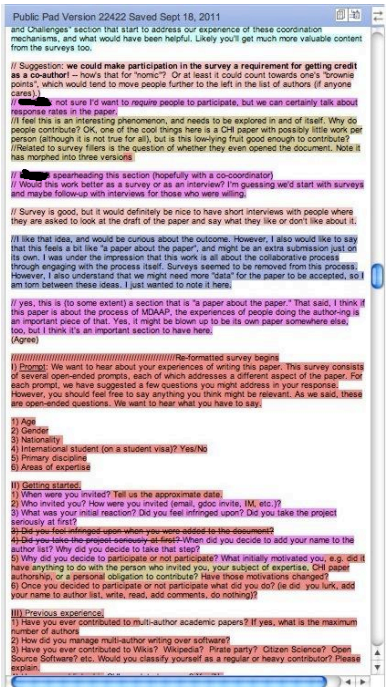
use of a collaborative online tool [3], but for an artificial writing task instead of a research publication. By contrast, we found it most convenient to gather data on collaborative writing in a research context by devising a real research situation in which we could make observations.

*Coordination Mechanisms*

In current academic practice, significant grants are often awarded to multi-institution and multi-discipline groups. In these projects, which can span years, there are often group meetings or phone calls to set an initial direction, with each institution taking a specific aspect of the work and developing it largely independently. Small teams can work more closely, but this takes significant effort (in terms of availability, direction, and roles). These examples suggest different models of coordination, as Van de Ven and others [22] have distinguished: e.g., pooled, sequential, reciprocal, and team modes.

With complex work such as authoring an academic paper, coordination is key to producing coherent and high-quality output. Different circumstances may have different coordination mechanisms that are suitable, for example: markets (first come first served), hierarchical management (project leaders), standardization (pre-defined templates), communication (discussion pages and talk between authors), and shared mental models (initial structure provided by type of community or template) [6, 14, 15]. This project used a mix of coordination mechanisms, as described below.

## Process



To provide a scaffold for the writing of this paper, a draft of an abstract and a few basic collaboration policies were established by the initial corresponding author (ICA) of the project, and specified in a non-editable web page: http://www.ics.uci.edu/~wmt/CHI2012CollaborativePaper.html.

The initial goal was to write a CHI 2012 full paper. After asking several colleagues for feedback on the core principles, the ICA began recruiting other authors through posts to mailing lists and existing social networks (recruiting in a "snowball" fashion) (see Figure 1).

During the first several weeks of the writing, we the authors collaborated using a Google Doc (viewable at http://goo.gl/RIUwC). However, with an influx of new authors responding to a post to the CHI mailing list, the Google Doc encountered an apparently unfixable error, perhaps having to do with the large number of authors (>25) attached to the project. The production was therefore moved to Etherpad, specifically, to the public installation hosted on PiratePad.net. EtherPad allowed us to finish a complete draft of the paper. Unfortunately, PiratePad.net produced an error that prevented the team from viewing the history of the document.

In the final weeks, an author survey was conducted and integrated into the paper. The paper was formatted and shortened to conform to the page limit, with abundant additional written content, notes, references, etc. remaining available in the online versions of the paper (viewable at http://piratepad.net/Massively-Distributed-Authorship-of-Academic-Papers).

The final edits were completed via an online, shared, and synchronized folder (Dropbox), in which

Public Pad Version 22422 Saved Sept 18, 2011
and Challenges' section that start to address our experience of these coordination mechanisms, and what would have been helpful. Likely you'll get much more valuable content from the surveys too.
// Suggestion: we could make participation in the survey a requirement for getting credit as a co-author! -- how's that for "nomic"? Or at least it could count towards one's "brownie points", which would tend to move people further to the left in the list of authors (if anyone cares!) ;)
// [redacted] not sure I'd want to require people to participate, but we can certainly talk about response rates in the paper.
//I feel this is an interesting phenomenon, and needs to be explored in and of itself. Why do people contribute? OK, one of the cool things here is a CHI paper with possibly little work per person (although it is not true for all), but is this low-lying fruit good enough to contribute?
//Related to survey fillers is the question of whether they even opened the document. Note it has morphed into three versions
// [redacted] spearheading this section (hopefully with a co-coordinator)
// Would this work better as a survey or as an interview? I'm guessing we'd start with surveys and maybe follow-up with interviews for those who were willing.
// Survey is good, but it would definitely be nice to have short interviews with people where they are asked to look at the draft of the paper and say what they like or don't like about it.
//I like that idea, and would be curious about the outcome. However, I also would like to say that this feels a bit like "a paper about the paper", and might be an extra submission just on its own. I was under the impression that this work is all about the collaborative process through engaging with the process itself. Surveys seemed to be removed from this process. However, I also understand that we might need more "data" for the paper to be accepted, so I am torn between these ideas. I just wanted to note it here.
// yes, this is (to some extent) a section that is "a paper about the paper." That said, I think if this paper is about the process of MDAAP, the experiences of people doing the author-ing is an important piece of that. Yes, it might be blown up to be its own paper somewhere else, too, but I think it's an important section to have here.
(Agree)
//////////////

whose names appear on the final paper unanimously responded that they would like to participate in distributed, collaborative online writing in the future.

Some problems arose due to the "recursive" nature of this paper, which confused some co-authors (and reviewers). The writing process resembled a game of Nomic [20], where the game is about changing the rules of the game itself. For example, arguments in one section of the paper might use quotes from another section as evidence. One author suggested that the outcome did a "poor job [of] collectively replicating Malcolm Ashmore's Reflective Thesis" [2]. The self-reflective nature of the papers led one of the CHI reviewers to describe the paper as "Seinfeldish".

### Distributed Authorship, Distributed Authority

Along with the relatively low levels of parallel communication about the paper (most discussion happened in the paper itself, with limited backchannel discussions), authors also felt a lack of any centralized control directing the paper. Contrasting it with other multi-author efforts in which he was involved, one author said that "with this paper, no one's in charge." Not having a centralized voice of authority became problematic in that the central thesis of the paper was not always clear.

Some appreciated this: one author enthusiastically compared the writing process to participation in a seminar. Others pointed to the concerns about editorial authority associated with removing content and finding consensus in multiple voices. In the words of one author, "I think it is quite chaotic to find a common structure and it is sometimes unclear: 3 authors comment and who decides finally? The main author?" These responses suggest an implicit assertion that it is necessary for the author(s) working on each section to understand how that section fits into the larger structure of the paper. The intermittent sense of confusion about the paper's aims reflects a certain assumption that many of the authors on this paper have about the academic writing process: that in order to be effective, all authors must have a clear understanding of the larger argument to which they are contributing.

### Medium of Collaboration

In writing this paper, the authors discussed a number of potential tools —existing and hypothetical— that could support the distributed authorship of academic papers. The most common type of tool considered were systems that support (simultaneous) multi-editing (cf. [17]). Some authors also suggested using a system like Scribtex (scribtex.com), though this would require working knowledge of LaTeX and so could have added a barrier to entry for participating in the collaboration. Other systems such as the CoWord plug-in for Microsoft Word could also have enabled simultaneous writing and editing.

However, it is possible that for the number of authors on the scale of this particular paper, viewing live simultaneous edits may be less important than simply having on-demand access and being able to track contributed text (who wrote what). For this, version control systems, such as Assembla (assembla.com) or Git might have been more effective.

Other tools can be integrated into the writing process to support particular sub-tasks. For example, the authors used Zotero (zotero.org) to collaboratively

build a reference library: https://www.zotero.org/groups/mdaap.

Although online tools appear to be a natural solution to the problem of working across time zones, they are, in their current state, lacking in support for multiple authors and voices. Authors supplemented the messiness of multi-authorship through other tools, such as EtherPad's built-in chat and e-mail. One author told us, "The chat was really nice—it was better than commenting in the paper directly since it didn't add additional 'noise'."

The technology, together with our governance choices, led to an emergent text that only weakly permits tracing of individual contributions. It was not obvious if a particular piece of text came from a graduate student, a researcher in industry, or a professor (which could be seen as a good thing). Figure 2 above illustrates how individual contributions were marked in EtherPad.

## Challenges of Integrating with Existing Practices and Publishing Infrastructures

This experiment helped emphasize how existing practices and infrastructures for the scientific publication process in our discipline are designed with relatively low numbers of co-authors in mind, and generally do not effectively support this kind of writing. For example:

### Online Submission Systems

Manually entering author data for a paper with thousands, hundreds, or even tens of authors can be a tedious process (if managed by one author), as supported by the current submission systems.

### Peer-review Practices

Many journals and conferences require anonymized submissions; however this type of article is difficult to make anonymous because a large number of researchers have been aware of the research effort (e.g. the author recruitment process involves broadcasting to a large community). Reviewer assignment is also challenging; many qualified reviewers may have been involved in the process or may have conflicts of interest with at least one of the co-authors. This issue can become problematic for program committee meetings as well, where members of the committee who have a conflict of interest in evaluating a paper must not participate in the discussion of the paper.

### Impact Measurement Practices

Some current practices for assessing the productivity and impact of researchers do not consider their relative contributions to papers. Two standard indices for measuring the impact of researchers, H-Index and G-Index, do not take into account the differences in the levels of contributions of co-authors. Thus, the growth of this form of scholarship may make these indices less useful as an estimate for academic impact.

The author list is not blank, nor replaced with a collective pseudonym (like *Bourbaki or D.H.J Polymath*), because the authors wished to acknowledge and take credit for their contributions, and agreed to be scientifically accountable for the content as a whole. We agreed that the author list should be ordered by placement "bids" from authors, with the ICA's judgment used to resolve ties.

DIGITAL LIBRARIES AND PUBLICATION FORMAT

Reference formats are also designed for small numbers of co-authors. For example, the APA and the Vancouver convention [11] limit the number of authors. This can demotivate authors who will not be among the top listed authors of a paper. Large author lists take up valuable space in the original publication, but will almost certainly not appear in future citations due to the annotation effort and/or space required. Moreover, even when browsing through papers in digital libraries or indexing systems that provide full metadata of papers, it may be of little benefit to browse through a long list of authors, not knowing how each of them has contributed to the paper.

## Discussion

We will now take a look at various strategies that can be used to mitigate the risks associated with our approach of wiki-like massively distributed authoring of papers. We begin by summarizing the main challenges.

*1. More authors means more content, but also more words thrown away.* Many of the words written by authors were deleted during the ongoing editing process. The sheer mass of deleted words might raise the question of whether authoring a paper in such a massively distributed fashion is efficient.

*2. Technology provides inadequate support for distributed authoring.* During the time we have been working on this project, we have tried, discovered, or created various tools for collaboration, but none of them appeared to be a silver bullet for all our needs.

*3. Task and domain differences.* There is a distinction between "collaboration on research" and "collaboration on writing". Although one normally follows the other, certain models of widespread collaboration might focus on, say, outsourcing experimentation (e.g., ScienceExchange.com), or ask for expert hands/eyes on certain parts of a paper (e.g., literature review, data analysis).

*Strategy 1: Know Thy Collaborator (and Granular Contributions)*

This project had many contributors, most of whom did not know one another. Additionally, several were from outside of HCI, and at least one from outside academia. The nature of the project meant that most participants added miscellaneous comments or perhaps took ownership of a section. At the end of the process, a small set of authors did significant restructuring and rewriting. Traditional collaborators often know and trust one another, with clearly designated leaders or first authors. Future collaborations should further explore the role of management (and associated functions such as task decomposition and assignment), relative to measures such as quality, coverage, coherence, and creativity.

*Strategy 2: Improved Tool Design*

From our experience it is clear that a system for writing massively distributed academic papers needs some way of maintaining and explicating the current state of the paper. At a high level, incoming authors need to understand what "phase" the paper is in (e.g., planning, writing, editing). Future tool design might look to decision support system literature [18] for mechanisms to aid the collaborative process. Sections that are "complete" may also need to be safeguarded, and potential editors pointed towards areas that still need further work. Having a strong sense of structure

could better enable such collaboration—although this paper began with a rough (section-level) outline, the structure became harder to follow as more sections were added and comments were written in-line. We attempted to maintain an up-to-date high-level outline of the paper as time went by, but a more sophisticated tool could have automated this process. More broadly, there is currently no simple way to curate or challenge a portion of the text, elicit responses from the authors, and apply changes that agree with a majority opinion or the opinion of more senior contributors that the authoring community might wish to empower.

*Strategy 3: Develop Suitable Coordination Mechanisms*
In writing this paper, it seems that communication between co-authors happened mostly in the context of the document itself. However, we also found that when authors come and go in the online environment, previous discussions are often brought up that had already been resolved, making the process repetitive at times. It has been a common practice in collaborative authoring tools to provide various forms of annotations to support the coordination of the authoring process [4]. Here, the primary method of coordinating activities was free-form annotations in the document. No annotation schema or rules were defined in advance, and the participants used various methods for distinguishing notes from content, such as using font styles (italic, bold, all-capitals), programming conventions (e.g., starting with //) or changing font color. For higher-level coordination needs, towards the end of the writing process, the ICA began using email to send out alerts and keep writers-up-to-date on process. This switch from the initial "hands-off" approach provided the structure we needed in order to meet deadlines. Further thought about how to best shape and signpost the project (both from a "writing" and a "research" standpoint) would help in future efforts.

## Future work

We have sought to identify challenges and opportunities in massively distributed authorship of academic papers, as well as reflections on the process and considerations for future researchers. Further experiments and repetition are required both to validate the analysis suggested here and to explore the relationship between this form of collaboration and different forms of research. For example, what research disciplines are best supported by this method of collaboration? What forms of research (e.g., user studies, design visions)? Future efforts along these lines might try some alternate methodologies (e.g., discourse analysis [25]).

Future work is also needed to develop the tools that can enable massively distributed authorship. For example, a website to act as a clearing-house for in-progress papers, ideas, or initial findings, would give authors a central location in which to contribute, as well as find new collaborators or stumble across relevant ideas, potentially aiding serendipity, insight, and discovery (as in [1]). Building an authorship community interested in shared process and/or content may help address the indifferent feelings many authors experienced about participation in this experimental effort.

Finally, this form of collaboration could also be extended to other parts of the academic publication process. For example, additional features could be integrated with WikiCFP (wikicfp.com) so that authors

can collectively determine what papers are being written for a given conference. Conferences and workshops could also produce post-event position papers written by the participants collectively, or include it in their proceedings a collaboratively written summary of the event.

## Conclusion

Massively collaborative crowdsourced projects, such as Wikipedia and Linux, affect aspects of many people's everyday lives. Open Data is a related emerging practice in the hard and computational sciences. The corresponding practices for "human sciences" are at present somewhat less clear.

In this paper, we consider one aspect of massively collaborative research that has potential to alter the way we work and discover: authoring. We identify challenges in: participation models for crowdsourced authorship; tool design and coordination mechanisms for supporting stages of a research and authoring process; and piecemeal contribution versus ownership and engagement. There are philosophical and practical questions with regard to contribution and authorship that we have only begun to discuss.

Academia itself is a massively collaborative undertaking, but massively multi-author writing of the kind described in this paper is relatively new. Nevertheless, with the spread of communication tools that facilitate various aspects of the process, and the exploration of new techniques for working together on large scales, this form of scholarship may begin to play an increasingly salient role in the pursuit of knowledge. When deployed well, collaboration can help our community become even more effective in its efforts to "contribute to society and human well-being" [5]. Research funds should be targeted towards developing more effective and rapid means to solve a range of research problems. Without sufficient investment in this domain, we will be bypassing some of the great advantages of living in a networked world.

## Acknowledgments

Many more people contributed to this paper than those currently on the author list. At times, the paper had as many as 38 people on the author list, and many others read drafts and propagated information about the project. The CHI reviewers provided helpful insights as well, and some of their ideas are in this version of the paper (although since they were anonymous, we were not able to invite them to be on the author list.) The authors thank the numerous institutions and other entities that have provided support for their respective participation in this research.

**Abstract.** This paper presents our work in progress on the Planetary system, along with a critical evaluation of the project relative to its stated goals and the goals of one of its main "clients", PlanetMath.org.

**Keywords:** mathematics, learning environments, encyclopedias, Drupal

## 1 Introduction

The metaphor or analogy implied by the title of this paper is that PlanetMath[3] is like an operating system for mathematics, and Planetary[4] is like a kernel for this system (think GNU/Linux). This analogy is both apt and sloppy.

In particular, PlanetMath is not a complete mathematics "userland". Indeed, it is best known for its mathematics *encyclopedia* which contains over 9000 entries, and defines around 16000 concepts (see [1]). Another key feature of PlanetMath is that every entry is *discussable* via its own attached, threaded, forum. PlanetMath has a variety of other features (like mathematics rendering, a term autolinker, and a workflow and authority model suitable to distributed encyclopedia authoring), most of which were developed in a custom system based on Perl and XSLT (called "Noösphere"), which was written up in Aaron Krowne's 2003 Master's thesis [2]. While this feature set has provided a (mostly) stable and functional basis for a popular community mathematics website for over a decade, the custom nature of the software made extensions and adaptations relatively scarce.

In 2010, the present first author was beginning a Ph. D. project on "Semantic Adaptivity and Social Networking in Personal Learning Environments" that aimed to extend PlanetMath so that encyclopedia entries were "connected to exercises and applications, preliminary materials, and resources for further learning", and to develop software that would track individual performance and provide personalized advice based on aggregated data.

Due to the extensive (and intensive) nature of software modifications that would be required to do this well, he welcomed the possibility to collaborate with Michael Kohlhase and his team at KWARC[5] on a complete re-build of Noösphere, using contemporary web frameworks, and integrating the "KWARC

[3] PlanetMath.org (2001-ongoing), http://planetmath.org
[4] The Planetary System (2010-ongoing), http://trac.mathweb.org/planetary
[5] http://kwarc.info

stack" of semantic technologies into PlanetMath. This led to an early prototype of the Planetary system being named a finalist in Elsevier's Executable Papers Challenge [3], but it was not until this year that an end to the PlanetMath rebuild appeared to be within sight.

The rest of this paper will descibe our technical achievements to date, discuss the immediate road ahead, and reflect on Planetary's potential, particularly from the point of view of its use on PlanetMath. (The reader is referred to [4] for a contemporary high-level overview of Planetary as a whole.)

## 2 A new "kernel" for math on the web

As indicated above, one of our main goals behind rebuilding PlanetMath's software was to be able to more easily bring new developers into the project. Another was to integrate new technologies.

After our first round of prototyping, Drupal 7 emerged as a good candidate solution for both of these issues. It is a popular system, with a wide variety of contributed modules – and it also supports a healthy marketplace for professional services. So far, the Planetary team has 14 contributors (most of them computer science students at Jacobs University, Bremen), with the current second author focusing on developing Drupal support for features and workflow similar to those found on PlanetMath.

We have found that there are some modules that can be installed and used directly, with minimal configuration (e.g. *privatemsg*, for the exchange of private messages between users) – others needed to be custom-built (e.g. support for *corrections*, essentially a custom form of bug report used to maintain accuracy and quality in PlanetMath's encyclopedia). Some others, like the *userpoints* module can be installed and used with minor tweaks. All in all, we depend on around 25 existing contributed modules, and have written a comparable number of custom modules. For a few legacy features, we took things in a new direction:

1. For mathematics rendering, we are using LaTeXML[6]. Full support for MathML lays the foundation for many other future services. (For example, our Executable Paper demo integrated JOBAD, a Javascript tool for interacting with mathematical documents while reading.)
2. In place of, or alongside, the legacy autolinking service, we have a new interactive ("semi-automated") autolinker, which should provide greater precision for links – and, again, open the door to a range of new interactive services during the document-authoring/editing process [5]. In addition, this feature is made possible by building on top of a real-time collaborative editor Etherpad, so we will get real-time collaboration on mathematics documents "for free".
3. For access to the encyclopedia by Mathematics Subject Classification (MSC), we used a new Linked Open Data (SKOS) implementation of the classification system [6]. This was motivating partly because it allowed us to develop

[6] http://dlmf.nist.gov/LaTeXML/

and demo an integration between Drupal, LaTeXML, and the Virtuoso triple store, which, again, will be useful in a range of future applications (e.g. we will be able to generate RDFa that can then be used to maintain backlinks, for example from an image to all of the articles that include that image).

There are some other features that have been developed for Planetary that are in use in other installation environments (namely, Michael Kohlhase's Computer Science courses), that are not yet integrated into our work on PlanetMath: specifically, an integration with SVN via TNTBase[7], which provides the ability to edit math on the web without ever opening a web browser, and a new books module, which provides support for lengthy documents. These features may eventually make their way into PlanetMath, but they can already serve to illustrate part of our goal in Planetary: to make a system that is useful in many different math-on-the-web contexts, with various features available in the various environments that need them.

One of our core aims in this regard is to make Planetary install "out of the box"; we are currently in the process of using Drupal's *profile* project to package up our work and support this. In future, this should be very helpful both for users and developers.

## 3 The road ahead

As we can seen in Figure 1, the latest version of Planetary captures many of the same interactions as the legacy version of the site, although the two sites are certainly not identical.

In the short months leading up to CICM in July, we aim to finalize the handful of features that remain unimplemented or partly implemented, and be ready to enter a "beta" with the new platform (i.e., ready to make it the software you see when you browse to PlanetMath.org). From a project management point of view, we have passed our last "milestone" and can now focus on feature-driven development. Our path to deployment on planetmath.org looks like this:

- May 4th: final module tweaking and building for features like requests, private messages, scoring, notices, and the object orphanage.
- May 11th: any final "alpha" features (e.g. finish integrating Etherpad), and a first round of optimizations.
- May 18th: A public "alpha" launch.
- June: Add any "beta" features that we need, in consultation with the PlanetMath user community.
- July: Final improvements readying the site for a switch over to the "beta".

[7] http://tntbase.org/

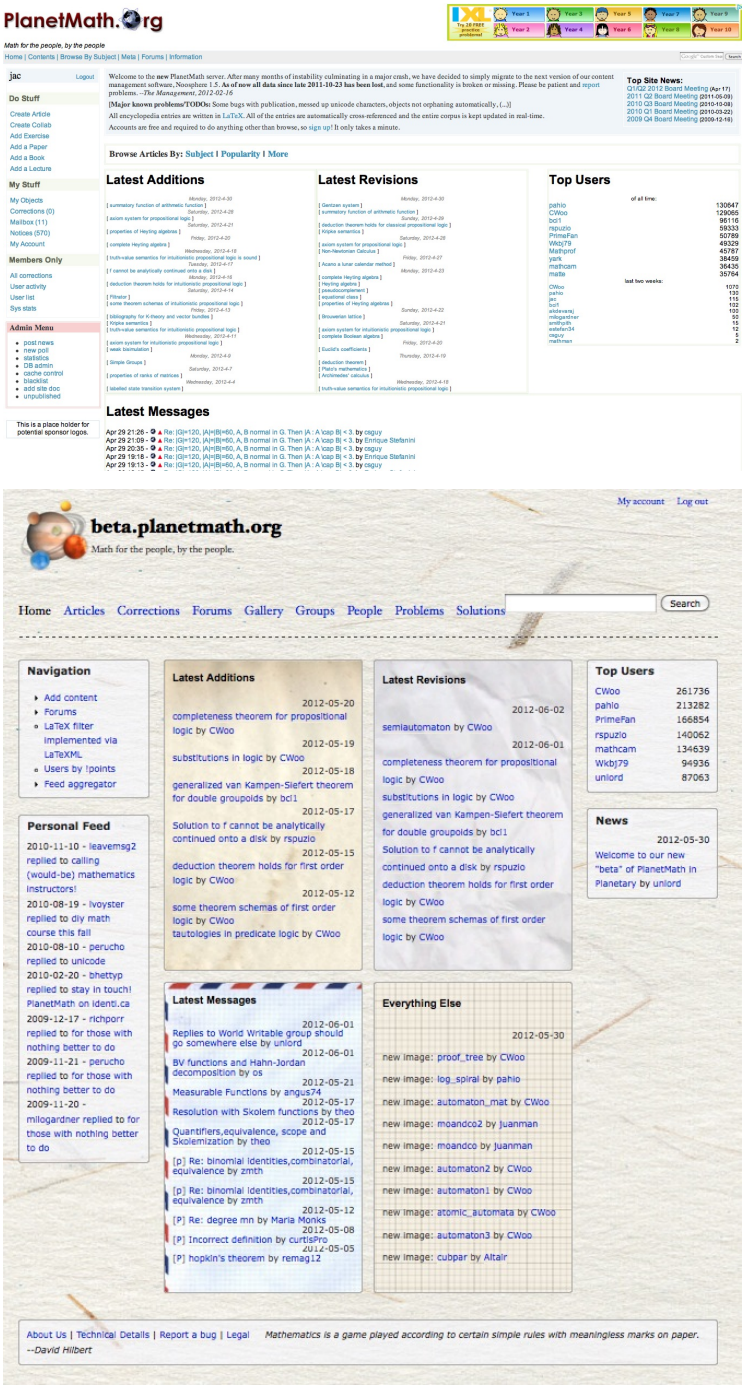

**Fig. 1.** The current PlanetMath webpage under Noösphere 1.5, and the new "beta" version.

## 4 A critical evaluation

The question we take up in this section is: is the Planetary system meeting the aims of its developers, and the needs of its user community? What could it do to improve?

Clearly, releasing the system on PlanetMath, and providing links the code[8] and installation instructions[9] should improve things dramatically. The new PlanetMath will render LaTeX blazingly fast, have better links, and a range of new features that address long-standing user concerns and also some nice surprises.

But our aspirations have in fact been much bigger – and switching to Planetary *should* play a big part in bringing them closer. Specifically:

- It is relatively easy to make new content types in Drupal, and we are introducing "problem" and "solution" node types, and allowing people to attach them to encyclopedia articles, and discuss problems with attached "questions" and solutions with attached "reviews".
- Our aim will be to develop some *semantically aware* activity tracking and "heads up" information for people using this system (see Figure 2). It is within reach to provide "related problems" using the MSC classification, but further analysis of theory dependencies (or approximations to the same) should allow us to give links to "simpler related problems", automating a key Pólya heuristic. Even without sophisticated tools, our hope is that a new generation of *students* will feel more encouraged to participate when problems and solutions become "first class" objects in the system.
- Our hypothesis is that the introduction of problems and solutions will provide a vital quality check, and enhancement. In short: encyclopedia articles that do not have attached exercises (or applications) should not necessarily be presumed to be useful. At the same time, exercises that do not have attached solutions may be too hard, i.e., the relevant subjects in the encyclopedia may not be sufficiently developed.

While we are *not there yet*, this is an example of the sort of thing we expect this technology together with the "encyclopedic approach", puts tantalizingly close to within reach.

[8] https://github.com/cdavid/drupal_planetary
[9] https://trac.mathweb.org/planetary/wiki/DrupalPorting

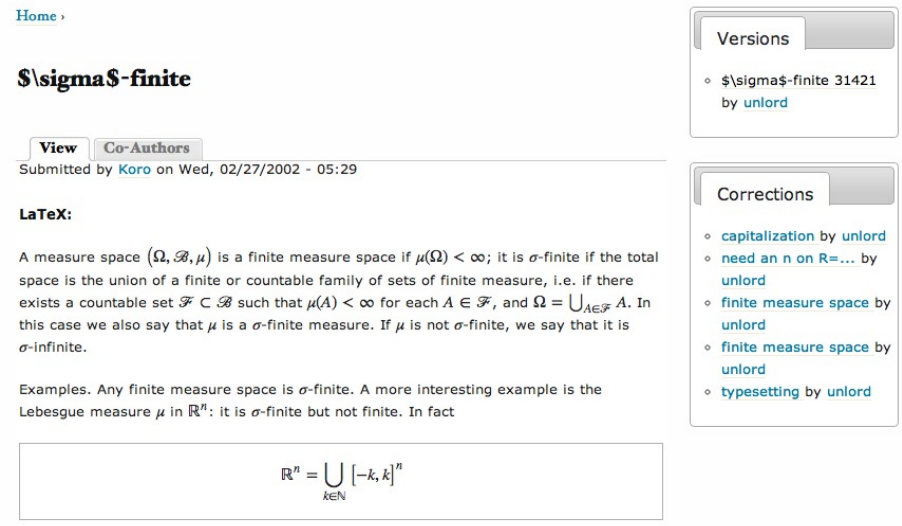

**Fig. 2.** Important information about articles (like outstanding corrections) in a "heads up" style display, shown here for a recent alpha version.

Note that PlanetMath, unlike, say, Wikipedia, is not *constrained* to be either "just a wiki" or "just an encyclopedia" – so, interactive problem sets and/or peer tutoring are welcome in PlanetMath, though they might not fit so cleanly within the existing Wikimedia family. Rather, the encyclopedic approach envisioned here connects interactions to a carefully curated and *systematic* knowledge base – in contrast with, for example, the StackExchange sites, at least in their current implementation.

In any event, the perspective developed above should brings up some big questions: in brief, what happens to mathematics teaching when students have access to a universal solutions manual for their mathematics course work? We may be able to *measure* whether lecture/homework/test is as effective for learning, as, say, participating in applied research projects.

Still, the hazard here would be to imagine that this can all happen overnight. It has taken PlanetMath 10 years to *define* 16000 terms, how much time will it take to provide a good *exposition* of those terms (always assuming that we do find users who want to participate in this process)?

Furthermore, as we have learned in the last few years, programming Drupal is not equally easy for everyone, documentation is not always clear (or available), and development work is generally a slow process (even with skilled programmers onboard). If the potentially revolutionizing changes (sketched above for mathematics education, but relevant also to research) of math on the web are

to be realized, most aspects of this project will have to scale up a lot – and hopefully coding will be less of a bottleneck.

## 5 Conclusion

We have described the Planetary system, and discussed its relevance to PlanetMath's continued project of building "a central repository for mathematical knowledge on the web, with a pedagogical slant." We expect the phase of work we will complete this summer to fully renovate and modernize PlanetMath. But once we have readied and deployed an extensible – and re-deployable – core, in a sense, our main work will just be beginning.

For example, we recall the meaning of "planet" from the blogosphere, i.e. planet-as-aggregator. Thinking in this way, PlanetMath might best fulfill its promise not *just* with a great new platform, but by successfully integrating content from other math on the web projects. This sort of aggregation service has yet to be realized, but forms a highly interesting direction for future work.

Indeed, if we are going to do anything about the "$500 million pricetag" for building a math-capable AI[10], we either have to bring about greater efficiencies, or spread the cost out over a relatively large number of people. Without making promises about just when this will be accomplished, we assert that we have, with PlanetMath and now Planetary, taken some vital steps in this direction.

**Abstract.** The Mathematics Subject Classification (MSC) is a widely used scheme for classifying documents in mathematics by subject. Its traditional, idiosyncratic conceptualization and representation makes the scheme hard to maintain and requires custom implementations of search, query and annotation support. This limits uptake e.g. in semantic web technologies in general and the creation and exploration of connections between mathematics and related domains (e.g. science) in particular. This paper presents the new official implementation of the MSC2010 as a Linked Open Dataset, building on SKOS (Simple Knowledge Organization System). We provide a brief overview of the dataset's structure, its available implementations, and first applications.

## Introduction

The Mathematics Subject Classification (MSC [7]) maintained by Mathematical Reviews (MR) and Zentralblatt Math (Zbl) is a widely used system for classifying mathematical documents. All major mathematical journals and digital libraries use the MSC[8], mainly as a means of structuring literature in libraries and for the purposes of retrieving information by topic. As the original format of the MSC2010 hindered its automated use and maintenance, we have reimplemented it as a machine-readable linked open dataset, which will soon be announced as the single official implementation.

* first author supported by DFG project I1-[OntoSpace] of SFB/TR 8 "Spatial Cognition" and EPSRC grant "EP/J007498/1 – Formal representation and proof for cooperative games"; second author by the University of Michigan. The final publication is available at http://www.springerlink.com.

[8] For details about this and about most other aspects of this project presentation, we refer to a full paper published recently [6].

*MSC Usage and Maintenance So Far* Previously, the right MSC class for a publication (e.g. 53A45 for "Vector and tensor analysis") was typically chosen by consulting a human-readable document. Web forms for uploading or searching publications typically required manual input of the desired MSC classes, rather than offering assistance. The source of the MSC had been maintained in one plain TEX file for almost 30 years. From this file, scripts produced several derived forms, including a KWIC index, a printable PDF, and HTML. Quality control of the source file with its custom macros could only be done by few experts, the derived forms did not particularly target machine processing, and the scripts that created them were once more custom, MSC-specific solutions.

*Requirements for a Reimplementation* After the *content* of the MSC2010 had been settled, MR and Zbl decided to technically reimplement the source, according to the following requirements: (1) **facilitate reuse**, i.e. facilitate access, search, queries, and auto-classification; (2) **facilitate maintenance**, i.e. preserve all of the original information, use a standard format supported by existing tools, enable integration of further maintenance information into the master source (such as the changes from MSC2000 to MSC2010); (3) **enable knowledge workers and service developers to adapt and extend** the MSC for their purposes, such as connecting mathematical subjects to related fields, adding descriptive labels in further languages, without affecting the core scheme; and (4) **allow end users to explore such connections** in order to **discover new knowledge**. We chose to reimplement the MSC2010 as an RDF Linked Open Dataset, using the W3C-standardized SKOS vocabulary (Simple Knowledge Organization System [8]), which had been in use in digital libraries for several years.

## Structure of the MSC/SKOS Concept Scheme

SKOS's built-in vocabulary covers a major part of the MSC concept scheme in a straightforward way; however, for full MSC coverage, we had to extend SKOS in an MSC-specific way. We summarize the design below but refer to [6] for full technical detail.

*Basics* The basic concept hierarchy was implemented as a SKOS concept scheme with 63 top-level concepts, which narrow down into 528 intermediate-level concepts, having 5606 final leaves. SKOS also supports collections of concepts besides the main hierarchy, such as "all historical topics". The 5-character MSC class numbers (e.g. 53A45) are used as URIs of the concepts for identifying them and making their descriptions technically retrievable (see below). SKOS allows for attaching multilingual labels to concepts; so far we have English, Chinese, Italian, and Russian, each from authoritative sources, and the RDF data model allows for maintaining further, non-authoritative translations separately. Finally, SKOS supports links across concept schemes, which we have so far used for making explicit the changes from MSC1991 and MSC2000 to MSC2010.

*Advanced Features* We go beyond the SKOS core, but follow established best practices, by linking MSC classes to concept schemes that have not yet fully been implemented in SKOS (the Dewey Decimal Classification). We extended the SKOS vocabulary with partitive relations, i.e. when a link to a related concept is restricted to a certain scope such as "numeric approximations" or "applications in physics". 0.4 percent of the concepts have labels containing mathematical markup, which cannot be expressed in Unicode but requires MathML. RDF supports XML in labels, but it conflicts with multilinguality – a problem unsolved so far. Finally, we attach some information, for which we have not yet designed a dedicated representation, such as co-classification policies, as generic notes to the respective concepts.

## Available Implementations

*The Dataset* We generated the new SKOS master source of the MSC2010 with a Perl script that translated the old TEX source to RDF/XML. We publish the data in four complementary ways, aiming to address a large audience of users and developers. The project page at `http://msc2010.org/mscwork/` contains links to all alternatives. For **linked data access** (i.e. directly retrieving an RDF description of each MSC class by dereferencing its URI; cf. [3]), we split the SKOS master file into one file per MSC class and serve the latter with the `application/rdf+xml` MIME type. For *querying* the dataset, we expose it through a SPARQL endpoint, i.e. a standardized interface for querying RDF. For *browsing*, we offer a wiki frontend. Finally, for application developers, we offer the whole dataset for download as self-contained files in several formats.

Easy and reliable maintenance requires a master source without redundancy, e.g. the concept hierarchy should not be represented both top-down and bottom-up. Linked data browsing, as well as other uses in large-scale applications that use plain RDF without inferencing support for performance, require a richer dataset with most practically relevant entailments expanded. We automatically create this expanded version by applying a set of first-order rules implemented in N3, covering a subset of the SKOS semantics and our MSC-specific extensions.

*In Use* The new implementation of the MSC2010 is currently in use on two websites linked from the project page. Both have been developed independently using the RDF-aware Drupal 7 content management system. On the homepage of the School of Mathematics at Aristotle University Thessaloniki (AUTH), we annotated the scientific fields covered by the courses and the faculty's research interests in terms of MSC/SKOS. The new version of the PlanetMath encyclopedia (shortly entering beta testing) is powered by the Planetary system [4]. In the old version, MSC-based navigation accounted for estimated 5–6 percent of all accesses. We have now reimplemented this functionality in a more generic way: all article metadata (including MSC classifications) are maintained within LATEX preambles, the articles are transformed from LATEX to XHTML+RDFa, from which RDF is harvested into an RDF triple store, which also holds a copy

of the MSC/SKOS dataset. This approach is more flexible than the older static MSC access: our plan is to use SPARQL queries to expose specific slices of the encyclopedia content (e.g. "all articles by my co-authors in algebraic topology"). The following listing, slightly adapted from the actual situation in PlanetMath, shows a SPARQL query that returns the subclasses of the given MSC class (which would actually be a parameterizable variable), and the number of articles classified with them[9]:

```
PREFIX msc:  <http://msc2010.org/resources/MSC/2010/>
PREFIX skos: <http://www.w3.org/2004/02/skos/core#>
PREFIX dct:  <http://purl.org/dc/terms/>
SELECT DISTINCT ?subclass ?notation ?label COUNT(?article) WHERE {
  msc:53Axx skos:narrower ?subclass . # get subclasses; then, for each subclass:
  ?subclass skos:notation ?notation ;                # get the MSC class number
            skos:prefLabel ?label .                   # get the preferred label
  OPTIONAL { ?article dct:subject ?subclass } # get classified articles (if any)
  FILTER langMatches(lang(?label), "en")                   # only English labels
}
GROUP BY ?subclass ?notation ?label   # grouping just needed for COUNT() to work
```

## Conclusion and Future Work

We deliver the first implementation of the MSC that is easily comprehensible to machines. It does not only facilitate maintenance and development of novel services, but the rigorous conceptual modeling approach [6] also helped to uncover issues in the MSC conceptualization, which we have now fixed. We are now planning to do three things in parallel: (1) refining the dataset implementation by making the internal structures of the MSC even more explicit[10] and by adopting further best practices for modeling classification schemes in SKOS [9]; (2) supporting the MKM community in building applications that make use of the MSC, using our new implementation; and (3) interlinking the MSC dataset with further mathematical and non-mathematical datasets, particularly including the OpenMath Content Dictionaries [5] and DBpedia [2].

## Abstract

The purpose of the paper is to design a rubric for assessment of informal learning in undergraduate level mathematics. Our proposed assessment strategy would support and parallel the mathematics learning environment we are developing at PlanetMath. PlanetMath is currently an open Web 2.0 system that consists of peer-produced encyclopaedia articles and forum discussions: we will add facilities for contributing textbook-style problems and solutions, and detailed activity tracking to model and support learning.

## Keywords

Mathematics, problem solving, assessment, learning, learning environment, knowledge analytics

## Introduction

We witness an increasing number of open online groups populated by self-organized and self-managed individuals who actively generate content in the attempt to foster learning communities open to all who wish to participate. These groups attempt to deploy the educational affordances (Kirschner, 2002) of Web 2.0 tools and technologies for information sharing, communication, content creation and collaboration. These affordances can enable participatory processes that can support multiple modes of learning in new open spaces, and blur the boundaries between production and consumption (Brown & Adler, 2008; Alevizou, Conole, Culver & Galley, 2009). Calls for learning approaches (especially those linked to socio-cultural theory) that are able to better exploit the educational affordances of Web 2.0 have been proposed (e.g., McLoughlin & Lee, 2007; Brown & Adler, 2008; Alevizou et al., 2010). However, claims about the educational and affective dimensions of online learning, e.g. that "these affordances stimulate the development of a participatory culture in which there is genuine engagement and communication, and in which members feel socially connected with one another" (McLoughlin & Lee, 2007, p. 667) invite further grounding in empirical research. Similarly, there seems to be a dearth of empirical studies addressing the learning-specific impact of Web 2.0.

In this paper, we will begin to tackle these broad issues in one concrete case. We describe an analytical framework for detecting when and how learning is taking place among participants in the open, peer-produced, mathematics website, PlanetMath.org. For this to work, we require learning-specific metrics: for example, "participation" is not in and of itself a particularly salient measure of learning. We follow the popular view that "mathematics is a language". In this view, learning mathematics can be modelled as a process of learning a specialized vocabulary, along with the technical grammar of proof.

We will flesh out this simple understanding in several ways. We agree with David Smith (2002, p. 5) when he writes, "learning mathematics is, first of all, learning, and only secondarily about mathematics." We will draw on microgenetic analysis, a collection of methods and techniques that have been used to study learning "as it happens" in a wide range of fields (Lavelli et al., 2005). Although we have not yet been able to validate this framework in practice, it has informed the design of the platform we are building, as we will describe below.

The paper is organized as follows: we describe PlanetMath and the ongoing project to turn it into a learning environment. We then discuss some theoretical perspectives that are relevant to our project and integrate these into our analytical framework. We conclude with some discussion of the implications of this endeavour for mathematical education.

## Overview of PlanetMath

PlanetMath.org (http://planetmath.org/) was initially developed by Aaron Krowne during the course of his Master's studies at Virgina Tech. PlanetMath is a virtual community and peer-produced repository of mathematical knowledge (Krowne, 2003). Its central feature is a peer-produced mathematics encyclopaedia, which has been written by a group of around 300 volunteers, and now containing nearly 9000 entries defining over 15000 terms. Similarly to Wikipedia, its contents are available under the terms of the Creative Commons By/Share-Alike License, but as a subject-specific encyclopaedia, it tends to have more specialised content (e.g. detailed proofs) (Corneli, 2011).

## The transition from reference resource to learning environment

PlanetMath's aim is to make mathematical knowledge more accessible, therefore it is a natural step to adapt PlanetMath's strategy of peer production to improve the site's support for learners. The approach underway takes the existing knowledge base as its core resource and extends it with a range of new materials and interactions focusing on problem solving – "the heart of mathematics" (Halmos, 1980). In short, our aim is to build a knowledge-rich online learning environment for mathematics.

A *learning environment* is made of human practices and material objects (Warger & Dobbin, 2009). It is a part of the human ecology wherein learners work alone or with others, using resources to pursue learning goals. It hosts the interactions of different types of learners, who interact, not only with each other, but also with artefacts, technologies and content (Nardi and O'Day, 1999). This "hosted interaction" feature is what distinguishes a learning environment from a learning object repository or digital library. Historically, PlanetMath has indeed hosted some interactions, namely those having to do with authoring and discussing mathematical content: however, its largest user population consists of non-logged-in visitors, for whom it serves as a reference resource. In the future, we aim to provide more active support for hosted interactions that help people learn mathematics.

### The learning design: PlanetMath's objects and environment

We follow Conole (2008) in thinking of "learning design" as a way of creating and representing practice.

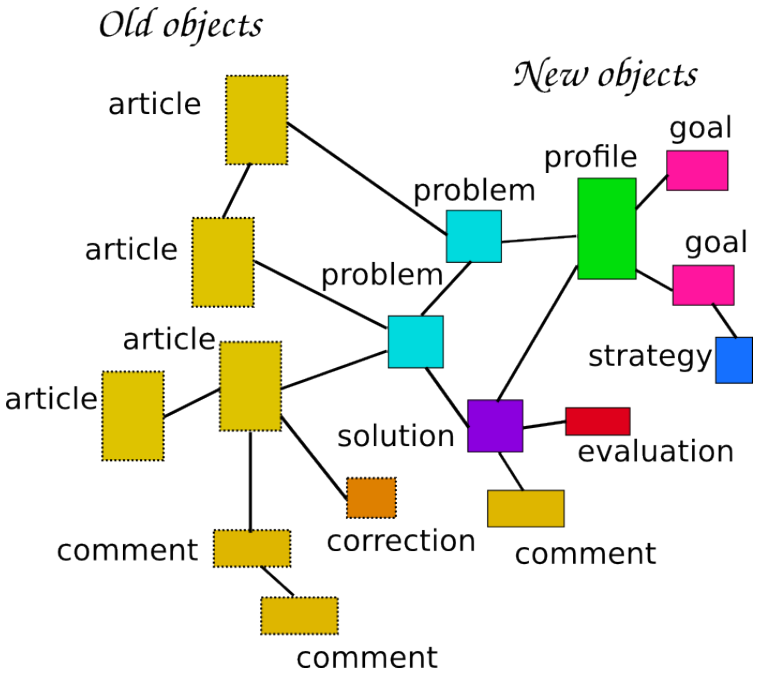

**Figure 1: The learning design in PlanetMath**

ISBN 978-1-86220-283-2

The design we are using to transform PlanetMath from being primarily a reference resource into a new learning environment (Figure 1) will include all of the traditional activities associated with building and maintaining PlanetMath's encyclopaedia (e.g., writing and editing articles, forum discussions, corrections and requests), and a new "problem solving layer", which contains problems, solutions, links from the problems into the encyclopaedia (and vice versa), as well as discussions about problems (including evaluation or marking), and course packets that combine problems with expository material.

Learning in this environment primarily entails solving problems, though numerous other activities will have learning relevance, e.g. asking a question, giving or receiving advice, or improving an expository text. From the user's perspective, the environment will offer some significant advantages over a standard textbook or problem archive. For instance, nothing is more daunting than being faced with a problem to solve and not knowing what the terms in that problem mean. On PlanetMath, we will be able to provide automatically-generated links to the definitions of technical terms in problem statements. Frequently, such definitions are not enough, and the user will be able to make annotations asking for hints about how to use the definitions. These requests will help improve the quality and relevance of encyclopaedia articles. Over time, we expect a large archive of hints and worked examples to accumulate, overcoming the cold-start problem for learners. In particular, as generations of learners interact with the site, sharing and reflecting on strategies for meeting their learning goals, a collection of efficient learning pathways should emerge. Our hope is this archive and guide will help learners connect to mathematics in a meaningful way: rather than having textbook problems serve as a daunting obstacle to application or research, they should, in this context, serve as stepping stones to relevant and meaningful engagement in mathematical practice.

### Theoretical perspective: PlanetMath as epistemic object and space for knowledge building

In this section, we describe two theoretical concepts we are exploring to underpin our analytic framework. Firstly, we suggest that PlanetMath can be conceptualized as an *epistemic object* (Miettinen & Virkkunen, 2005). Miettinen and Virkkunen explain that epistemic objects or objects of inquiry are constructed and are not fixed, but are projected towards something that does not exist yet. We suggest that PlanetMath can become an epistemic object in this sense – an "instruction manual", whose process of development and refinement can contribute to transforming mathematics education. This is a process that develops by critique, questioning, and even dissent at the content level, as well as an ongoing and parallel process of tinkering on the infrastructural level. Conceptualizing PlanetMath as an epistemic object connects us to the socio-cultural historical approach, which examines the foundations of learning not in "abstract rules", but in material artefacts (Miettinen & Virkkunen, 2005). In this view, PlanetMath can be seen as a shared artefact objectifying forms of expression of cognitive processes and patterns that exist outside of the minds of individual participants. The process of learning mathematics can be embodied in this artefact's constituent tools and signs. Drawing on Vygotsky's (1979) concept of mediated action, a participant can internalize these, by interacting with other users, with content, and with tools. PlanetMath becomes a new means of mediating the activity of learning mathematics. One can imagine it providing many of the same features as textbooks (problems and exposition), as well as many features that textbooks cannot provide (like peer-to-peer conversations and mentoring).

Secondly, we suggest that the concept of *knowledge building* is relevant to examining the foundations of mathematics learning in such a concrete setting. Knowledge building refers to the production of objects (Bereiter & Scardamalia, 1996), which, in PlanetMath, include, for example, production of articles and solutions to problems. Similar to work in research and scientific communities, learners build knowledge by asking cutting-edge questions that help the community advance its collective understanding, by engaging in problem solving and by seeking to understand problems at deeper levels (Scardamalia & Bereiter, 2003). Again, this co-created knowledge, which is relevant to the goal of learning mathematics, is embedded in shared artefacts (e.g., structures, algorithms and proofs, explanations and justifications) (Bereiter & Scardamalia, 1996).

## Developing an analytical framework to detect learning

Viewing PlanetMath as a learning environment encompassing interactions among humans, technology and artefacts such as terms, articles, problems and solutions, our proposed analytical framework aims to examine the process of learning in a social context and to support the cycle of knowledge building in which learner-produced materials have an important role to play.

Our suggested framework consists of three layers. The first layer will keep track of what happens in the learning environment at the "micro-developmental" level, in the following way:

ISBN 978-1-86220-283-2

- Examine user activities, such as solving a problem, asking a question, and giving a hint.
- Examine the vocabulary (specialized terms) that people use in texts they submit to the site.
- Assume that when this vocabulary is used in a solution that has been marked correct, then the vocabulary has also been used correctly.

The second layer is inspired by the analytical toolkit (ATK) used by Chan, Lee and van Aalst (2001) to examine knowledge-building inquiry and discourse among high school students using the Knowledge Forum. In addition to providing measures of activities in the Knowledge Forum, including notes written, notes read and keywords used, the toolkit assesses aspects of the development of collective knowledge, using an adaptation of principles designed by Scardamalia (2000). The toolkit aims to detect:

- *Working at the cutting edge*: participants work to advance individual and collective knowledge, and not to reiterate what is already known.
- *Progressive problem solving*: participants pursue problems at progressively deeper level, which means that when participant in the community understands a problem, s/he uses this learning to deepen the understanding of the problem and solve it.
- *Collaborative effort*: participants need to share understanding and to advance collective knowledge.
- *Identifying high points in the discourse*: participants note contributions that help them understand a problem better and advance collective knowledge.

Additional situational or relational features that can describe mathematical problem solving behaviour (Hosein, 2009) which fit at this layer include:

- *Processing level*: deep or surface learning, e.g. as evidenced by attempting to work through problems versus merely browsing solutions.
- *Quality of self-explanation*: the learner is able to explain why they are doing what they are doing.
- *Exploration*: the learner makes use of available tools and content.

We will aim to build software that can identify in an automatic way these aspects of learning and knowledge building. For example, site-wide analysis of vocabulary usage would enable us to identify someone who uses a completely new term to be "working at the cutting edge". We can also use the network of interlinked documents to understand how a given activity relates to another ("progressive problem solving").

We will extend our model of simplified "language acquisition" (Layer 1) and different measures of engagement (Layer 2), with a third layer, which deals with the substance of problem solving itself. Before describing this third layer, we make some remarks on how we plan to analyse the data we will be gathering.

### Microgenetic analysis

Open online learning environments provide researchers with access to all of the same data that participants use to communicate with one another (Stahl, 2006). Researchers have access to a natural data set similar to that provided by "talk-aloud protocols", which can provide detailed evidence of learning and development. This kind of data – and the informal, ad hoc interactions that generate it – matches well with some of the ideas and techniques of microgenetic analysis. The microgenetic approach studies learning as a process, rather than the outcome of a process (Lavelli, Pantoja, Hsu, Messinger & Fogel, 2002). The approach examines moment-by-moment changes observed in a short period of time, often for a high number of separate observations, but not necessarily subject to the same staged treatment patterns found in longitudinal studies. Observations tend to be analyzed intensively, both qualitatively and quantitatively. Microgenetic approaches have been used to take into account the social process of development, in which individuals learn concurrently in a distributed fashion (Fischer & Granott, 1995). This method seems particularly well suited to our informal peer-based learning context, where a pre-test/post-test method for assessing learning quality would generally be inappropriate or infeasible. Statistical analysis of this sort of data presents some unique challenges (Cheshire et al., 2007). A higher-level challenge appears when we try to take what we've learned and apply it to shape practice. We give an indication of how we plan to address this challenge in the following section.

## Applied heuristics: a Minskian approach

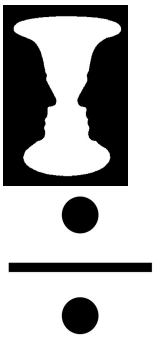
ISBN 978-1-86220-283-2

The purpose of this section is to establish a third layer of analysis, which we would position above the use of specialised mathematical vocabulary and below social dynamics like "working at the cutting edge". Namely, here we look for engagement with the methods of mathematical problem. This layer includes the traditional "grammar of proof" (e.g. proof by induction or *reductio ad absurdum*). However, importantly, it also includes heuristics, and this is what we focus on in the current section. The treatment here is not exhaustive, indeed, a key feature of this layer is that it can expand to include any new heuristics we discover.

In one of his memos for the One Laptop per Child (OLPC) project, Marvin Minsky (2008-09) wrote:

> Children [...] learn words for various objects and processes – such as addition, multiplication, fraction, quotient, divisor, rectangle, parallelogram, and cylinder, equation, variable, function, and graph. But they learn only a few such terms per year – which means that in the realm of mathematics, our children are mentally starved, by having to live in a "linguistic desert." It is hard to think about something until one learns enough terms to express the important ideas in that area.

His concern, however, is, not merely with increasing the rate of vocabulary acquisition, but with learning ways to think and problem solve. He quotes Allen Newell (1955):



> The essential point of efficient learning is that, after you have solved a problem, it is not enough just to remember the answer: you need to remember the strategies that you used to discover that answer.

Minsky then proposes several example heuristics (ways of thinking about problems) that might be taught, or detected when they are employed (Table 1). He also suggests some meta-level heuristics:

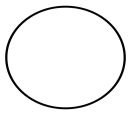
- *Select appropriate representations*: Building an understanding of the problem or goal at levels ranging from deciding its domain, finding suitable parameters or making an intuitive sketch.
- *Find appropriate analogies*: Some of the most useful results in mathematics combine ideas from disparate sub-fields (like geometry and algebra); further, some say that mathematics is the science of patterns, so knowing how to look for useful patterns is a vital skill.
- *Deploy negative expertise*: Knowing what has failed to work in the past can be useful.
- *Construct more realistic self-models*: As one gains experience, one can understand better how one thinks.

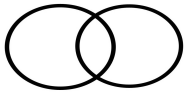
These heuristics are of course not specific to mathematical problem solving per se, but the mathematical domain is indeed rather keenly focused on problem solving. In some sense, we could say that all "informal" mathematical speech represents use of heuristic reasoning. As with the four criteria from Chan, Lee and van Aalst (2001) mentioned earlier, we would like to be able to automatically detect patterns like "reasoning by analogy" or "deploying negative expertise". Many of these could be identified from textual features drawn from the informal parts of mathematical speech ("by analogy" or even "it easily follows"), or else via explicit discourse markers, following the example of the "Dangerous Bend" sign employed by Bourbaki (Kranz, 2011) – one use for the icons supplied in Table 1. In analysing a given text, we can also draw on some of the literature about technical language, such as, for example, Trimble's (1985) discussion of technical rhetoric.

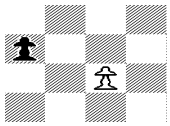
If a problem seems familiar, try reasoning by analogy. If you solved a similar one in the past, and can adapt to the differences, you may be able to re-use that solution.

If the problem still seems too hard, divide it into several parts. Every difference you recognize may suggest a separate subproblem to solve.

ISBN 978-1-86220-283-2







| | |
|---|---|
| If it seems unfamiliar, change how you're describing it. Find a different description that highlights more relevant information. |  |
| If you get too many ideas, then focus on a more specific example – but if you don't get enough ideas, make the description more general. |  |
| If a problem is too complex, make a simpler version of it. Solving a simpler instance may suggest how to solve the original problem. |  |
| Asking what makes a problem seem hard, may suggest another approach – or a better way to spend your time. |  |
| When your ideas seem inadequate, remember someone more expert at this, and imagine what that person would do. |  |
| Whenever you find yourself totally stuck, stop whatever you're doing now and let the rest of your mind find alternatives. |  |
| The best way to solve a problem is to already know how to solve it – if you can manage to retrieve that knowledge. |  |
| If none of these methods work, you can ask another person for help. |  |

**Table 1: Problem-solving heuristics suggested by Minsky, together with mnemonic diagrams**

## Discussion and Conclusion

In this paper we have described our strategy for converting PlanetMath into a learning environment suitable for self-directed, peer-supported study of undergraduate-level mathematics. In this endeavour, we aim to make sense of series (and, indeed, networks) of informal activities, which can include significant high-level thought.

We can contrast the approach that has been developed at Khan Academy (khanacademy.org/), where they have dealt with somewhat similar issues but in a very different learning ecosystem, based on expert-produced videos and workbook-style problems for grade school students. We can also contrast StackExchange and similar Q/A sites, where one-off technical questions are discussed (typically with links to "the answer").

In the PlanetMath case, we are aiming for something very different: co-construction of an increasingly complete mathematical artefact, dealing not just with "the answers" but with the processes and strategies for thinking about how to get to answers. Although we are not in a position to ensure the availability of peer support, we suspect that, on average, learners will be able to use PlanetMath to avail themselves of "observation, coaching, and successive approximation" (Collins et al., 1989). If these efforts are successful, significant changes in the way mathematics education works may follow. In particular, as we mentioned above, we hope that PlanetMath's "super-textbook" will help learners connect to mathematics in a way that is relevant and meaningful to them. Indeed, the idea that we could collect all textbook answers in one place does bring to mind a very interesting question, about why mathematics education in schools and universities has been focused on solving "textbook problems" that have already been solved many thousands of times before. Can improved use

ISBN 978-1-86220-283-2

of technology give us something better? While we believe the answer here should be a fervent "yes", details will be determined in practice, not a priori. Still, we may at this time consider similar questions about other domains of knowledge. Can we develop similar "application layers", similar to our "problem solving layer", that re-use encyclopaedia content from Wikipedia or other knowledge resources in peer produced learning environments or interactive learning tools?

Turning this question around, what might general-purpose "social layers" for Open Educational Resources (such as p2pu.org or OpenStudy.com) glean from a subject-specific project like PlanetMath? It appears that the biggest strength of our proposed approach to detecting learning is its three layer framework: we can detect specialised vocabulary use, socio-technical features like "working at the cutting edge", and manage a catch-all category of heuristics which can be used to detect and talk about different ways of thinking. While there is a somewhat domain-specific mathematical flavour to this approach, we feel it poses an interesting model for educators and educational scientists working in other fields to consider adapting to their purposes. Further work will need to be done to establish whether this analytical framework can effectively detect patterns of learning.

**Abstract.** Paragogy is a theory of peer learning: we endeavor to say how it works, and how it works best. This paper outlines paragogy's contemporary relevance and expounds its principles, showing their connections to other theories. We present an extended example of paragogy in practice, where we use it to evaluate our experiences working at the Peer 2 Peer University (P2PU).

**Keywords:** paragogy, peer learning, P2PU

## 1 Introduction

We use the term *paragogy* to characterize the critical study and practice of peer learning (literally, "para-" alongside, "-gogy" leading, here adapting the classical concept of *pedagogy* and the recent notion of *andragogy* [10] to a peer learning context). The fact that *παραγωγή* is a word in Greek meaning "production" shall not dissuade us from this new usage in English. Indeed, along with J. Philipp Schmidt, executive director at the Peer–2-Peer University (P2PU)[3], we believe that learning is frequently found at the heart of peer production processes [19]. In the case study that forms the heart of *this* work (Section 6), we will use paragogy to evaluate our experiences as course facilitators at P2PU.

Although peer learning has been the subject of various studies, it is typically given a secondary role, within a pedagogical framework. This rather staid definition, from a book that approaches peer learning from the perspective of cognitive psychology, illustrates our point [16]:

> *Peer learning is an educational practice in which students interact with other students to attain educational goals.*

Although this definition is not in itself unreasonable, we are fascinated by the growth and evolution of opportunities for learning outside of formal institutions. A recent article from Fast Company, an influential business magazine, gives an expanded view of peer learning:[4]

[3] http://p2pu.org

[4] http://www.fastcompany.com/1746901/how-mint-execs-new-company-is-going-to-make-teachers-out-of-us-all

> *Just as more and more employees are expected to have basic multi-media skills – the ability to blog, for example, or to shoot images or videos on their smartphones – so will they be expected to have the basic ability to share knowledge with their peers.*

Thus, peer learning can of course take place between non-students, and it can concern productive, as well as educational, goals.

In addition to an increased emphasis on informal learning in the workplace, recent years have seen the rise of open, online spaces that serve the needs of learners via a commons-based approach. Here we cite Cormac Lawler's recent work on Wikiversity ([11], [12]). Lawler uses and advocates an *action research* approach, with thematic questions "What does it take to change a given system? [...] and how does the process of changing a system develop our knowledge about that system?" We have brought these questions to P2PU, and by extension to the education system that P2PU critiques ("The current model of higher education is broken..."[5]).

Our aim is to develop a set of "good practices" around peer learning, suitable for use by everyone involved (individual learners, organizers, administrators). A model is provided by two related works, one from Crowston *et al.* concerning "open source software success" [5] and the other from Resnick *et al.* on "starting new online communities" [17]. We will, however, have to wait for a future work to bring these contributions into one coherent frame with paragogy.

## 2 The challenge

A. T. Ariyaratne's essay on *Rural Self Help* [2], one of the foundational writings of the Sarvodaya Shramadana movement in Sri Lanka[6], begins:

> *Nobody needs to teach rural communities about "group effort" and "self-help". [...] The real question, therefore, is to examine what are the constraints that exist inhibiting the expression of their group effort and self-help qualities designed to improve food and nutrition levels, clothing, shelter, health, sanitation, education and cultural life?*

We approach peer learning in a similar spirit: it is something we all know how to do, but can't always do well. Intuitively, there are bound to be difficulties for a group of peers studying a subject together, outside a traditional classroom or without a teacher. Indeed, peer learning is different from other forms of group effort, the proverbial "barnraising" for example, in which the persons involved can be presumed to know how to build barns – or at least to know someone who knows, and stand ready to take orders. Typically, peers are not experts in learning, didactics, or in the subject they are studying, and are faced with multiple difficulties associated with putting together knowledge about the subject, assembling a suitable learning strategy, and communicating with one another.

## 3 What paragogy has to offer

We have five principles, with which we endeavor to both describe the phenomenon of effective peer learning, and to prescribe key aspects of its best practice.

1. **Changing context as a decentered center.**
2. **Meta-learning as a font of knowledge.**
3. **Peers provide feedback that wouldn't be there otherwise.**
4. **Learning is distributed and nonlinear.**
5. **Realize the dream if you can, then wake up!**

Generally the ideas embodied in these principles are not unique to paragogy, indeed, we will try to ground each of them in previously existing literature, while showing their relevance to peer learning.

*1. Changing context as a decentered center.* In paragogy, we recognize that we are not merely teachers or learners, but are actually co-creating the learning context as a whole. The central role of environment is not unfamiliar in constructivist thinking about education ([23], p. 4):

> *Thinking of instruction as an environment gives emphasis to the 'place' or 'space' where learning occurs. At a minimum, a learning environment contains: (1) the learner; (2) a 'setting' or a 'space' wherein the learner acts, using tools and devices, collecting and interpreting information, interacting perhaps with others, etc.*

Again, in the paragogical view, the environment should not be taken as "given" but should instead be viewed as co-created by peers.

*2. Meta-learning as a font of knowledge.* Here we are concerned both with efforts to "learn how to learn", and efforts to learn how to support others in their learning efforts [20]. Further, while it is a good idea for any organization to learn its business well [13], learning about learning is especially vital for those in the learning business. In peer learning, that is all of us.

*3. Peers provide feedback that wouldn't be there otherwise.* Learners must not simply seek confirmation of what they already know, they must confront and make sense of difference as part of the learning experience. Clearly, differences pose challenges but these are worth grappling with. Firstly, for psychological reasons: in many domains feedback is only available from peers (but of course peer learning can be relevant in domains like rock climbing and computer programming, where automatic feedback does exist). Secondly, there are philosophical or political reasons to affirm difference. In a space like P2PU, which aims to provide "learning for everyone, by everyone, about almost anything", we can hardly avoid developing an "understanding of social relations without domination in which persons live together in relations of mediation among strangers" [24].

*4. Learning is distributed and nonlinear.* Learning does not go in a straight line [8]. In particular, involvement in co-creating the learning context becomes an important "strand" in the paragogical understanding of peer learning.

*5. Realize the dream if you can, then wake up!* Without clear goals, there will be be nothing to realize. Without critical thinking about goals (leading us to change them), learning is a mostly passive game. Paragogy calls for a strategy of "deliberate practice" [7].

## 4 Literature review

The paragogical principles were conceived by turning Knowles's principles of andragogy [10] on their edge. In succinct form, these principles are:

1. **That adult learners are self-directed.**
2. **That they bring a wealth of experience to the educational setting.**
3. **That they enter educational settings ready to learn.**
4. **That they are problem-centered in their learning.**
5. **That they are best motivated by internal factors.**

Blondy [4] points out both uses and challenges for each of the Knowles principles, focusing on how they work in online learning environments. For instance, with reference to the first principle, "*Cheren stated that while learners may express a desire to be self-directed in their learning, most lack the required understanding of learning necessary to be self-directed and thus need guidance and encouragement in the learning process.*"

While our principles can be read as a critique of andragogy, it is largely a matter of point of view: thus, unlike andragogy (which takes the view of the adult educator) or pedagogy (which again studies teachers teaching learners), and unlike heutagogy [9] (which focuses on self-directed learners), as we have seen above, paragogy focuses on cases in which learners are actively engaged in co-creating their learning environments. In formulating our first principle, we drew on Nishida's notion of *basho* ("shared context in motion"), which looks at the way a context constrains or supports different types of (inter-)actions, and simultaneously at the ways in which we can (re-)shape the contexts we find ourselves in [1]. Thus, instead of asking whether or not learners are self-directed, we would follow Bingham [3], and assert that self-directedness is only meaningful within a relational context (e.g. within a social field). So much for the first principle, others are subject to a similar re-thinking.

Paragogy is not the only framework that has been used to study peer learning. We'll mention Scardamalia's 12-point framework for Knowledge Building [18] and Mwanza's 8-step process coming from Activity Theory ([15], cf. [14]). Scardamalia's 12 "socio-cognitive and technological determinants of knowledge building" are framed by the idea of collective cognitive responsibility in the workplace. (Collective responsibility for creating a suitable learning context would be

another way to describe our first principle.) Scardamalia's more extensive framework will in general support a more detailed analysis, but may be less intuitive to work with. Mwanza's eight steps map a given situation to Engeström's activity triangle [6], and are used to generate design requirements. This method is less normative than either Scardamalia or the present work, but also less specific. As with the work on software and community-building best practices mentioned in the introduction, we must defer the task of fully comparing and contrasting these approaches with our own.

## 5 Implementing paragogy

How to implement the principles? In this paper we will incorporate a strategy used in the US Army's training programmes: the *After Action Review* (AAR) [21]. As the name indicates, the AAR is used to review training exercises. It is important to note that while one person typically plays the role of evaluator in such a review (and despite the fact that military personnel are differently ranked), the review itself happens among peers, and examines the operations of the unit as a whole. The four steps in an AAR are:

1. Review what was supposed to happen (training plans).
2. Establish what happened.
3. Determine what was right or wrong with what happened.
4. Determine how the task should be done differently the next time.

The stated purpose of the AAR is to "identify strengths and shortcomings in unit planning, preparation, and execution, and guide leaders to accept responsibility for shortcomings and produce a fix." We note here the similarity of the AAR to the action research cycle [11].

## 6 A case study in paragogical evaluation

The paragogy principles provide guidelines on best practices for building successful peer learning experiences. In this section we will apply these principles to evaluate the lessons learned from our work at P2PU as facilitators in 2010–2011. For each of the principles we run through the steps of an After Action Review to look at how well the principle was implemented.

### 6.1 Changing context as a decentered center: mapping system dynamics and semantics

*Review what was supposed to happen.* We both organized multiple courses where participants were supposed to interact and learn about the subject matter: Collaborative Lesson Planning Fall 2010 and Winter 2011 (co-organized with Dr. Majorie King); DIY Math; Math for Game Designers; Open Governance and Learning (co-organized with Marisa Ponti); and, in Spring 2011, Shaping P2PU[7], which was an "intervention" based on a preliminary version of this section.

[7] `http://new.p2pu.org/en/groups/p2pu-the-course/`

*Establish what happened.* Due to critically low participation, the mathematics courses did not run to completion. Participation in Collaborative Lesson Planning and in Open Governance and Learning was minimal, but sufficient for a conversation to be sustained for the entire 6 week session. The theory of paragogy was born in an effort to understand how to produce successful courses. Finally, as of the time of this writing, 32 people have signed up for Shaping P2PU, but so far participation has been very low.

*Determine what was right or wrong with what happened.* In the more active courses, there were nice examples of learning by course participants.[8] Low participation was common across P2PU, as illustrated by Dan Diebolt's graphical analysis, which showed that participation within courses was uneven and falling.[9]

*Determine how the task should be done differently the next time.* Our best experiences as course organizers happened when we were committed to working through the material ourselves. Combining this with gently prompting peers to follow through on their commitments could go a long way towards keeping engagement at a reasonable level – but this only works when commitments are somewhat clear in the first place. The case of Shaping P2PU shows that organizer commitment is not enough. In this case, we feel that further clarification about the aims and intentions of those who are already highly involved in shaping the organization would improve things.

Looking at this another way, the P2PU ecology contains an implicit rubric for learning and engagement: from the time a member signs up for a course, to its completion, peers go through a cycle.[10] As we understand this cycle better, it should be possible to evaluate it for quality. Then P2PU could implement more formal check points throughout the cycle, requiring participants to specify, reaffirm, or adapt their commitments in relationship to judgments about quality.

### 6.2 Metalearning is a font of knowledge: transparency, accountability, and tone

*Review what was supposed to happen.* Support for community members was offered as a P2PU course (Course Design Orientation), in mailing lists, via weekly phone calls, in a Q&A issue tracker, and via other informal channels. Participants in courses were presumed to be ready and willing to contribute in a useful fashion.

*Establish what happened.* Core members do hold themselves accountable, but this behavior is not necessarily transferred or communicated to new members, for whom accountability is low. Course participants frequently disappeared.

[8] E.g. `http://open-governance-and-learning.posterous.com/`
[9] `http://bit.ly/lqPChA`, `http://bit.ly/kH89OP`
[10] See `https://wiki.mozilla.org/Drumbeat/SoW-engagement-ladder`

*Determine what was right or wrong with what happened.* Core members are doing a lot of work, and the project is moving forward, with grant funding, incorporation, and several new staff positions. Apart from contractual agreements within the nonprofit, community members have little or no accountability to one another. Governance follows a "rough consensus" model (after David Clark's "We reject: kings, presidents and voting. We believe in: rough consensus and running code."[11]). As implemented at P2PU, the rough consensus model has its strengths, in particular, it helps avoid tyrannies of the minority in the mailing lists. However, there are a number of ways in which rough consensus seems incomplete.

*Determine how the task should be done differently the next time.* It is typical for online communities to have strictly enforced community norms. It would be helpful to have a concise discussion of these available, together with up to date information on "best practices" for organizers and participants. The current Course Design Handbook provides one starting point, but it falls short of being a complete guide to P2PU.[12] This sort of resource would be particularly useful for newcomers and people who cannot attend the community telephone calls.

### 6.3 Peers provide feedback that wouldn't be there otherwise: dealing with problems in a respectful way

*Review what was supposed to happen.* Discussions about P2PU happen in the community mailing list and other places mentioned above. Bug reports are supposed to go into the Lighthouse tracker.[13]

*Establish what happened.* Discussions about P2PU happen in many places (e.g. in courses). Even within the mailing list, it can be difficult to keep track of the full range of ideas circulating at any given time. There has been some talk about using the Lighthouse tracker for organizational matters, but this hasn't taken off. Earlier experiments, like using a shared spreadsheet to keep track of organization-level tasks, appear to have been undersubscribed.

*Determine what was right or wrong with what happened.* Apart from development work, it can be hard to tell what's happening around P2PU. Presumably participants who have identified critical and unsolvable problems simply leave. The Q&A tracker and mailing list both provide ways to build factual knowledge, but seem less effective for building *strategic* knowledge.

*Determine how the task should be done differently the next time.* In a traditional university, there are typically a lot of ways to resolve problems without dropping out. P2PU's new "Help Desk" could, indeed, help with this issue – if people use

[11] Cf. `http://www.wired.com/wired/archive/3.10/ietf_pr.html`,
[12] `http://wiki.p2pu.org/w/page/27905271/Course-Design-Handbook`
[13] `http://p2pu.lighthouseapp.com/dashboard`

it.[14] The Help Desk and Q&A tracker will also function as a light-weight way to build certain kinds of organizational knowledge. However, there could be more clarity about how to contribute to the process of "shaping P2PU".

One fairly straightforward thought would be to add support for site-wide content tags. Site-wide tags would allow people who are not interested in "meta-discussions" to easily ignore them, whereas a space like Shaping P2PU could aggregate and build upon the already-ongoing platform-level discussions that have arisen in other groups. Tags would provide other learning-specific benefits, including the ability to give and receive light-weight feedback about contributions, and to build a portfolio showing the impact of one's work. This would, in turn, foster a culture of accountability.

### 6.4 Learning is distributed and nonlinear: design considerations

*Review what was supposed to happen.* People are supposed to choose and assemble suitable learning resources (blogs, OER, etc.) for their courses, in which everyone is supposed to learn something.

*Establish what happened.* This is essentially what happened, but it is hard to measure when and whether knowledge was gained.

*Determine what was right or wrong with what happened.* The organization is striving to handle the complexity of life online, for example, by integrating RSS feeds into the site to allow learners to transparently draw in work that they are doing elsewhere. This system is explicitly in an experimental "beta" stage, and quality control has a somewhat precarious meaning in a beta or "eternal beta"; on the other hand, this makes life interesting.

*Determine how the task should be done differently the next time.* In terms of measuring learning, P2PU would have to work hard to use anything but "participation" as a proxy value. In terms of broader issues of quality control, one serious thought is for P2PU core members (including staff) to use the platform to organize their activities – entirely in the open.

### 6.5 Realize the dream if you can, then wake up: high level roadmap

*Review what was supposed to happen.* At one time, the high-level vision was arguably a Declaration of Independence from Formal Education.[15] But arguably each participant has their own vision.[16]

*Establish what happened.* P2PU recently had its first board meeting, but, so far, documentation about the organization's vision and roadmap have not been presented to or affirmed by the user community (nor has the user community presented any stipulations to the organization).

[14] `http://new.p2pu.org/en/groups/p2pu-help-desk/`
[15] `http://www.youtube.com/watch?v=t8wxUbU1W_0#t=12m11s`
[16] `http://www.youtube.com/watch?v=t8wxUbU1W_0#t=13m12s`

*Determine what was right or wrong with what happened.* P2PU has made considerable progress (e.g. in the form of successful grant applications), but without more transparency about these efforts, the ability of non-core members to learn from organizational successes is limited. This, of course, limits the ability of volunteers to contribute to further successes of this sort, and may, to some extent, limit the ability of volunteers to "strike off on their own" to pursue alternative development goals.

*Determine how the task should be done differently the next time.* It is our firm belief that P2PU should work on a public roadmap that leads from now up to the point where the vision is achieved. Both vision and roadmap should be revised as appropriate.

## 7 Conclusion

Reflecting on education-relevant potential of new media, Martin Weller writes: "*It is [...] no easy task to adopt a decentralised model, since it will require massive procedural, economic and professional change in higher education*" [22]. We would argue that what's new here is not simply a disruptive force in the traditional educational landscape: there is also a compelling chance to understand learning better. We hope that further developments in paragogy can contribute to this process in a practical way.

We close with a quote from Young [24] that sums up our current sentiments, and points to a possible wider role for paragogy:

> *If institutional change is possible at all, it must begin from intervening in the contradictions and tensions of existing society. No telos of the final society exists, moreover; society understood as a moving and contradictory process implies that change for the better is always possible and always necessary.*

# PlanetMath Redux: Web 2.0 infrastructure for mathematical problem solving

Joseph Corneli[1], Constantin Jucovschi[2], and Alexander Mikroyannidis[1]

[1] Knowledge Media Institute, The Open University, MK7 6AA, UK
[2] The KWARC Research Group, Jacobs University, D-28759 Bremen, Germany

**Abstract.** This demo shows work in progress on a Web 2.0 infrastructure for mathematical problem solving. Our aim is to make undergraduate-level mathematics easier to learn: our strategy is to link problems and solved examples to prerequisite material drawn from an existing free/open mathematical knowledge repository, the encyclopedia at PlanetMath.org.

**Keywords:** mathematics, learning environments, problem solving

## 1 Overview

We are building a new web infrastructure for mathematical problem solving, with the aim of making undergraduate-level mathematics easier to learn. Our strategy is to build a layer of contributed problems and solutions that are linked into the peer-produced mathematics encyclopedia developed and hosted on PlanetMath.org[3]. PlanetMath has been an active content-producing community since 2001, with around 300 authors contributing to an encyclopedia defining more than 15000 mathematical concepts. Support for problem solving would alter the space significantly, making it easier for students to contribute, and opening up new channels for peer tutoring.

The knowledge rich, systematically constructed, peer reviewed encyclopedia will provide relevant material that undergraduate students would not find in online mathematics learning environments like OpenStudy[4], Khan Academy[5], MathOverflow[6], and Virtual Math Teams[7], though we can draw ideas and inspiration from all of these. Some of the core strengths of our system will be:

- A low floor (easy to participate just by asking a question: keywords will be automatically linked to their definitions) and a high ceiling (the possibility to explore advanced topics and help others);
- Simple models of learning (vocabulary acquisition, enactment of various mathematical roles) will help us keep track of students progress, making the system suitable for peer-supported self-study [1];

[3] `http://planetmath.org`
[4] `http://openstudy.com`
[5] `http://www.khanacademy.org`
[6] `http://mathoverflow.net`
[7] `http://vmt.mathforum.org/vmt/`

– Teachers will be able to use the site to run their own courses (cf. earlier classroom experiments by David Smith [4] and Robert Milson [5]);
– Solutions will be available to logged in users only; activity tracking can be used to discourage cheating, and data mined to generate recommendations.

After some initial prototyping [3], we decided to realize the system as a collection of plugins and modules for the popular open source content management system, Drupal. The current demo shows some of the core "Web 2.0" features, and provides a basis for subsequent semantic extensions (such as disambiguation and linking within formulas).

Concretely, in addition to a port of legacy PlanetMath content into the Drupal framework, our demo will show: (1) Autolinking of technical terms from problems and solutions into the PlanetMath encyclopedia (adapting [2]); and (2) learner profiles and basic activity logging (see Figure 1).

**Fig. 1.** A user's contributions as they appear within a learner profile

The realized system is anticipated to help cut time and other costs for both learners and teachers, by being a source of problems and solved examples, cross-referenced with prerequisite readings, all of which can be remixed in purpose-made study guides. We expect that our approach to knowledge reuse and peer-to-peer learning will be applicable in related technical fields.

# Personalised Peer-Supported Learning: The Peer-to-Peer Learning Environment (P2PLE)

**Joseph Corneli**

j.a.corneli@open.ac.uk

**Alexander Mikroyannidis**

a.mikroyannidis@open.ac.uk

Knowledge Media Institute, The Open University, United Kingdom

## Abstract

The Peer-to-Peer Learning Environment (P2PLE) is a proposed approach to helping learners co-construct their learning environment using recommendations about people, content, and tools. The work draws on current research on PLEs, and participant observation at the Peer-to-Peer University (P2PU). We are particularly interested in ways of eliciting explicit, coded, user feedback, and in monitoring the transitions from state to state within the PLE. We discuss the ways in which these ideas can inform the design of a platform for peer-supported study of university-level mathematics.

## Keywords

Peer Learning, Personal Learning Environments, Feedback

## I. Introduction

The Personal Learning Environment (PLE) lies at the forefront of personalised and self-regulated learning online (Chatti, M. et .al. 2007) The use of online forums, blogs, social networks and other Web 2.0 tools for learning purposes is also increasingly typical, even among co-located groups.

In this paper, we will investigate design issues around personalised and peer-supported learning, drawing on participant observation in a new learning-oriented online community, the Peer-to-Peer University (P2PU)[1]. We will make use of the existing PLE literature, and walk through an extended thought experiment where we look at how our ideas could be applied in a mathematics learning context.

The main idea we investigate in this paper is that of the Peer-to-Peer Learning Environment (P2PLE). Our thought is that since learners typically work through tasks together, or with a degree of peer support, they would benefit from access to a sophisticated, personalised, socially-aware task tracking system.

We are agnostic as to whether this system is closely integrated with a given online community, or makes use of the Web-as-Platform model. Part of the view of PLEs is that learners will make use of a wide range of tools and interactions in any case (Willson et.al., 2008). Features of the P2PLE could be implemented in either scenario, and, indeed, we have already seen proofs-of-concept for both (we will discuss this in the following section).

Both self-directed learning and peer collaboration are already quite strongly supported in Web 2.0 environments. What remains to be seen is how to improve the learning experience by making use of this data as we move towards platform with stronger support for semantics (Web 3.0). The P2PLE proposal indicates the scope of data that we can usefully gather, and makes some initial recommendations for how to use this in the concrete instance of mathematics learning.

## II.Background

Personal Learning Environments (PLEs) have shown evidence of facilitating learning and addressing the current limitations of Learning Management Systems (LMS). A PLE can be broadly defined as a facility for an individual to access, aggregate, configure and manipulate digital artefacts of their ongoing learning experiences. Compared to a typical LMS, where the learner is restricted by the lack of adaptability and responsiveness of the learning environment, the PLE follows a learner-centric approach. It allows the use of lightweight services and tools that belong to and are controlled by individual learners. Rather than integrating different services into a centralised system, the PLE provides the learner with a variety of services and hands over control to her to select and use these services the way she deems fit (Fiedler and Väljataga, 2010; Zimmerman, 1989).

For example, n the context of the European project ROLE (Responsive Open Learning Environments - www.role-project.eu), we are supporting learners for lifelong and personalised learning within a responsive open learning environment. Figure 1 shows a PLE developed by the ROLE project for the Open University. The purpose of this PLE is to support students in studying climate change and

[1] http://p2pu.org

sustainable energy by providing them with a set of learning tools in the form of widgets. Within this environment, learners use a search widget in order to find learning materials from a variety of repositories, including OpenLearn (www.open.ac.uk/openlearn), iTunes U (www.apple.com/education/itunes-u), Wikipedia (www.wikipedia.org), SlideShare (www.slideshare.net), and YouTube (www.youtube.com). Learners also collaborate with their peers via widgets offering videoconferencing and real-time document editing functionalities. Learners can personalise this environment by adding tools from third-party widget providers, such as the Google gadget directory (www.google.com/ig/directory).

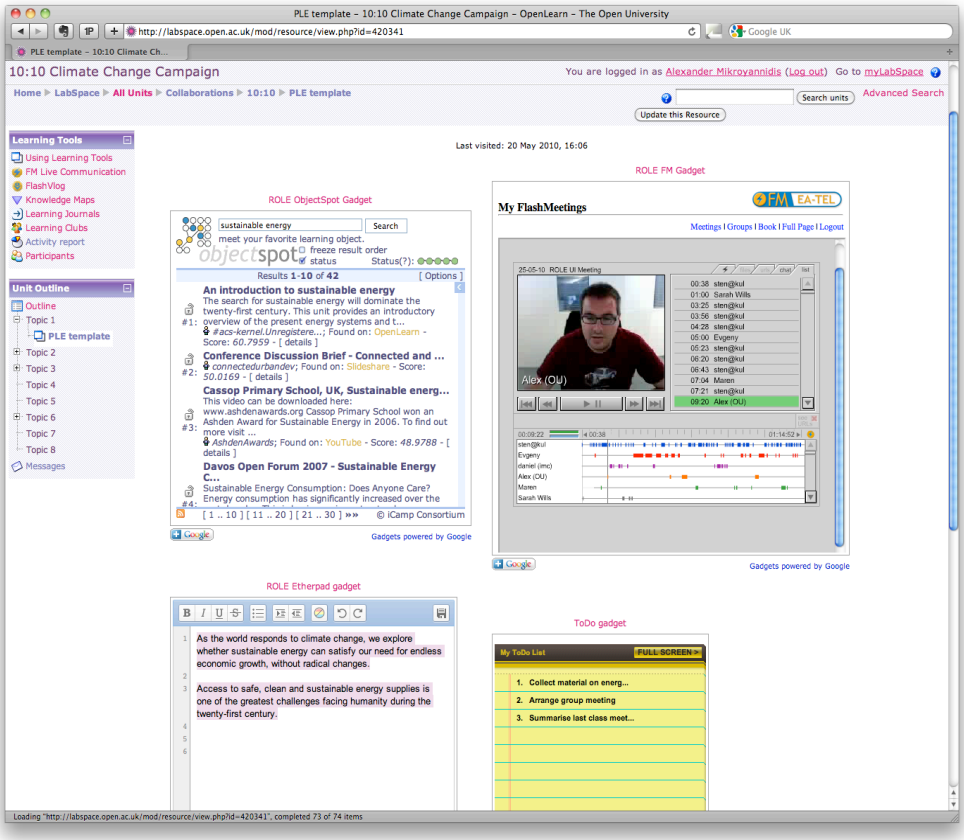

Figure 1. A PLE for finding learning resources and collaborating with peers

How do we think about quality in a PLE? Studies can have been made to determine whether people like their experiences working with a PLE, and the tools can be adapted accordingly; this approach is the state of the art in PLE research.

However, a PLE is all about live, interactive adaptation to the needs of the user. Accordingly, there ought to be a way to measure various aspects of quality within the PLE itself. Here we suggest a lightweight approach to user feedback that uses distributed evaluations of all of the components and activities that comprise the environment.

How might this work? We know that a PLE user assembles various components and performs various activities with these tools. Many of these activities are social – collaborating on a project, giving feedback to one another, and so forth.

Importantly, objectives are selected from a larger set of possible objectives, tools are selected from a larger set of possible tools, peers are selected from a larger set of possible peers, and so forth. Each of these choices represents an implicit judgment about quality – such choices have the potential to be particularly revealing when they change over time.

However, there is a degree of implicitness here that confounds things. Unless we have a way to make the judgments explicit, we won't know whether someone is moving on from a given activity because they are finally satisfied with the results, or because they have grown hopelessly frustrated.

Within the current conception of PLEs in the ROLE project, an explicit evaluation or reflection phase is introduced, which can make more of these judgments explicit – see (Fruhmann, 2010) which builds on the theory of self-regulated learning developed in [8]. Here, we look for ways to wrap evaluation and reflection even more tightly into use and participation.

This requires lightweight ways to communicate sentiments about activities. For example, in response to a given blog or forum post, a reader might say "This blog post was exceptionally well-written, I learned a lot from it", or they might say, "You know, this post was interesting, but it happened to lead me off on a direction that wasn't really relevant to my learning project" -- or they might say, "Reading this post was a waste of my time." In the case of blogs, feedback of all sorts is currently handled through the comment system.

However, feedback could easily be coded. We can start with the popular idea of bookmarking or "starring" content, but we suggest that stars should be used to give feedback, and not simply as bookmarks (Figure 2). In other words, starred content should also show up in the profiles of the people who contributed the content. The set of codes should be expanded, providing readers with a set of ratings that convey significantly more than just "thumbs up" or "thumbs down". The "superstars" lab feature recently mainstreamed in Gmail gives an idea of what the UI might look like (but Gmail doesn't currently propagate information on which posts have been starred back to the content creators).[2]

In a learning context, detailed feedback would be particularly relevant to (peer) producers of content, and also to educators or technologists who are building tools. A peer learner might, for example, request evaluation along a certain set of dimensions: "I'm really trying to work on my writing quality, please let me know if you find my argument cogent or not." A technologist might be happy to learn about novel uses for the tool they've developed.

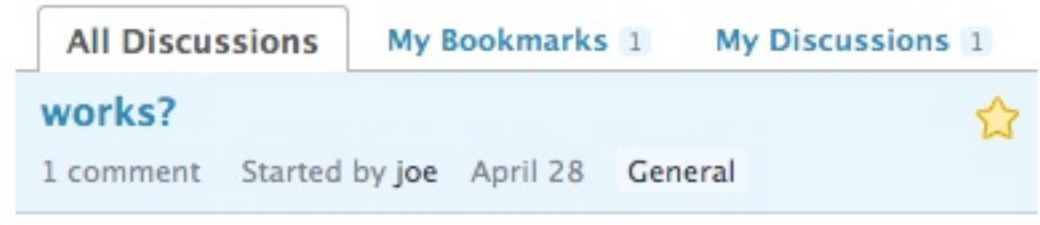

Figure 2: We start with the popular idea of starring content, but suggest that stars should show up not just as "my bookmarks", but also in the profiles of people who contributed the content.

[2] http://gmailblog.blogspot.com/2011/05/3-labs-graduations-1-retirement.html

Thus, a targeted set of feedback options could be requested in addition to open feedback. (Targeted requests for feedback are known to work well in writers' workshops, for instance!) As proof of concept, we note that multi-dimensional judgments have been used to good effect for years in the Slashdot community, while the Facebook "Like" button is a more recent example showing that light-weight quality judgements can be widely distributed.

Of course, such judgments can be applied to all aspects of the learning context: tools, objectives, activities, peers. There is wide precedent for various sorts of feedback presented by technologies ranging from UserVoice to LinkedIn. The real question is how feedback is going to be used. This is the main issue we take up in the rest of the paper.

## III. A simple scenario

Anne, Betty, and Charlie are working together on a paper they plan to present at a conference. Betty and Charlie have a good collaboration session drafting some initial content -- but it turns out that Anne can't make it to the scheduled meeting. She shows up later and does some editing in place, finalising the text. Betty later adds some diagrams. Anne then decides to put together a short film to accompany the presentation. Finally, it happens that the conference is near Charlie's hometown, so he's the one who makes the presentation.

This simple scenario shows three axes: People, Tools, and Activities. The range depicted in Figure 3 is meant to suggest a small slice of data about a much larger environment: in general, there would be more items along each of the pictured dimensions, and more dimensions as well. In particular, here we've aggregated activity over a certain short period of time.

Looking at other slices along the time dimension might reveal that our protagonists collaborate like this frequently -- or perhaps we would learn that they end up collaborating in a similar way, but with other people.

What we don't know just from looking at this picture is how the presentation went, or how any of the protagonists felt about any of the steps in the process. We would need another dimension to learn that Betty and Charlie do indeed find Etherpad to be an effective tool, or that Anne actually prefers it when she gets more help with her video work. But these sorts of judgements could be added as extra dimensions.

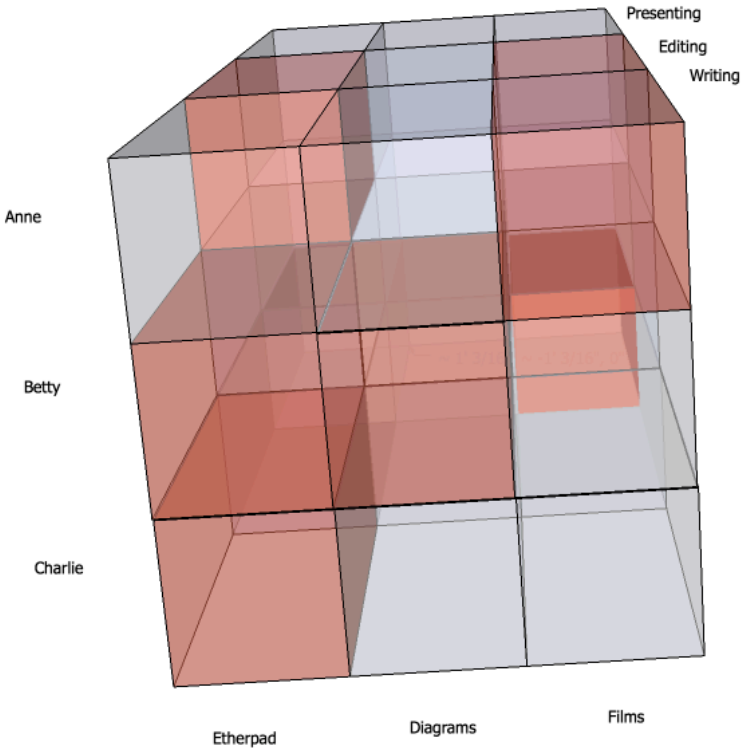

Figure 3: A 3-dimensional grid showing people, technologies, and tasks

## IV. Requirements for Peer Learning

We begin with a couple of basic axioms about feedback.

1. Feedback doesn't do much good if the agent(s) receiving the feedback can't use it.
2. Giving feedback tends to be an "extra step", so we should make it useful for people to give (or they won't do it).

An example of (2) that we discussed above: "starring" items is useful in approximately the same way that bookmarks are useful, but if handled properly, the starring action can provide feedback to content creators. The rest of this section looks at different transitions that can happen in learning. This section is based on recent observational study at P2PU (Corneli,J. and Danoff, J., 2011), in which we developed a framework of five principles that describe successful peer learning experiences. Here, we reframe these principles in active terms, looking at what changes ("Deltas") take place in peer learning.

### 1. Changing the nature of the space: "changing context as a decentred centre").

This could happen at a technological level (e.g. an administrator or programmer adding a new feature to the platform), or, importantly, on a qualitative social level (e.g. by a user making a comment that changes the tone of the conversation).

2. **Changing what I know about myself : "meta-learning as a font of knowledge").**

Users can be kept accountable for their actions and celebrate their contributions by means of a record kept on their user profiles. A user profile that keeps track of things I rated highly, and ratings of my contributions (or recommendations of me) from others would be very useful. In response to changes in my profile, I may update the criteria I'm asking for feedback about.

3. **Changing my perspective: "peers provide feedback that wouldn't be there otherwise").**

Users can have constructively critical views on technology, strategy, or content. Sometimes actions speak louder than words.

4. **Changing content or connectivity: "learning is distributed and nonlinear").**

In a peer-managed environment, "design" can happen on an ongoing, ad hoc, basis. Without changing the "nature" of the space itself, it is possible to change the content, for example by adding or removing a given feed or tool.

5. **Changing objectives: "realize the dream if you can, then wake up!").**

Individual and collective goals and objectives are important as a way to discuss and critically examine progress. Since goals and objectives change (particularly once they have been achieved, but for other reasons as well), there should be ways to users to adjust their goals. Changes to shared goals and objectives should typically be negotiated.

## V. Support For Interpersonal Communication

Is a social context, the five different kinds of changing features discussed in the previous section are workflow and communication issues, *par excellence*.

The various transitions could happen quickly (e.g. by adding a particular tag to some piece of content), or build up more slowly (e.g. by continual feedback from peers about a given topic).

It is important to note that a given piece of content -- like a person -- can be in several categories at once. This leads to the idea of remixing content by sharing it between several courses or groups at once. This idea is akin to the concept of "internationalization", insofar as we consider content that be immediately used a range of "locales".

In this view, a given discourse context, such as a development project, is akin to a simple "language". Indeed we might find many development projects that are mostly distinguishable by their language choices. Until the learning environment supports content that is adaptable in this manner, the environment may suffer from an unnecessary degree of balkanisation.

Since the P2PLE adapts content bi-directionally between several sources, constructive activities can take place in different locales or peer groups, and share across boundaries. Importing changes can be selective based on local evaluations of quality (it's OK if other people use the content in a different way).

The next section will look at a concrete case.

## VI. Peer Interactions in a Mathematics Learning Environment

There are any number of websites that offer help with or learning resources for mathematics. One has been well studied is the Math Forum, where "virtual math teams" have received particular attention (Stahl, 2009). Another more recently developed site is the Kahn Academy, which provides videos and sequenced review problems. At present, Kahn Academy materials do not incorporate peer interactions explicitly, but peer support has been used to good effect in classrooms where the Kahn materials have been deployed.

However, these, and most, mathematics learning platforms focus on pre-university material. We will look back at the ideas generated in earlier sections and think about how they would apply in a P2PLE for university level mathematics.

We will look at the project underway to add facilities for problems and solutions to PlanetMath.org, a community-produced mathematics encyclopedia. This will be viewed through the lens provided by the five points discussed above.

### 1. Changing the nature of the space

As technological facilities develop, new features will be rolled out regularly, moving from basic support for adding and discussing problems and solutions, to automatically linking the problems to related articles in the encyclopedia, all the way through to a recommender system that will mine previous user interactions to suggest useful problems or readings to try next. Although problems will be separate from the encyclopedia, their introduction will change the nature of the space: people will now be able to ask "Which encyclopedia articles are missing problems?" or "Are the encyclopedia articles that are connected to the current problem well-written?", for example. Looking at expository material as part of an ecosystem that contains problems and solutions adds a very useful check on quality. Small independent changes to encyclopedia articles that adjust them to serve the needs of learners are expected.

### 2. Changing what I know about myself

As individual learners accumulate a track record of uploading and solving problems, asking for and offering help, giving feedback on and modifying encyclopedia articles to suit, etc., they should get a better sense of how they learn best. They should be able to ask for specific kinds of feedback and see how their progress improves (e.g. in formulating proofs or demonstrating an understanding of the concept of a limit). They should be able to keep track of particularly helpful and particularly non-helpful suggestions offered by peers or by the recommender system.

### 3. Changing my perspective

Hopefully, peer mentors -- and system developers -- will be able to learn from learner feedback about what's helpful and what's confusing. Feedback should be particularly valuable to learners ("Wow, I didn't even know there was such a thing as spherical trigonometry!"). Ideally, giving and receiving feedback will be comfortable for all involved.

### 4. Changing content or connectivity

In addition to peer-producing mathematical content, our hope is that learners and other contributors will be able to develop their own semantic queries. Such queries could be used to identify holes in the corpus, or interesting relationships between activity patterns. Not everyone needs to be able to build these queries to use them, e.g. to generate a feed showing all the latest additions of problems having to do with tori or klein bottles.

### 5. Changing objectives

A shortcoming that was noted in the previous decade of PlanetMath's existence was that support for individual "projects" was not particularly strong. For example, a project to improve the entries about real numbers chose to base its operations on the organisational wiki rather than in PlanetMath itself.[3] Content quality in PlanetMath has so far been maintained using a "correction system" that points out places where individual articles are mistaken or could be improved. In order to support the production of educational content, it would be good to generalise the correction system to include ranges of content (sub-collections of the encyclopedia or sub-areas of mathematics).

## VII. Conclusion

We have discussed a model of learner interactions that takes into account people, tools, activities, and other dimensions. In particular, we have focused on feedback about these items as an ancillary set of dimensions. Time is one of the most important dimensions, and, in some cases, we may be able to infer judgments from time-delineated data -- however, we've focused on ways people can get and give explicit feedback, keeping in mind two axioms, that the feedback should be useful to both receiver and sender.

We've examined general-purpose criteria for peer learning environments, which have arisen in the context of P2PU, and applied them to generate some initial design requirements for an ongoing to convert a peer produced mathematics encyclopedia into mathematics learning environment.

The thought we wish to conclude with is that in today's global context, we are often in touch with peers from all over the world. There is an increasing need courses that cross natural language boundaries, and for specialized technical literacies. But our ability to understand one another well depends partly on the means that we have to express our thoughts, ideas, and concerns.

Technologies that are able to provide learners with feedback on their expressions – whether coming from a peer, or from an algorithm – can support the learning process. Following the outline of the previous two sections, our suggestion would be to focus on developing technologies (ranging from light-weight mechanisms like rubrics or rating systems, to sophisticated text mining tools) that learners can use to detect, highlight, and share information about the changing nature of the space, its content and connectivity, and their own self-knowledge, perspective, and objectives. We look forward to future work on these issues, building on the ideas in this paper.

# Chapter 15
# Crowdsourcing Education on the Web:
## A Role-based Analysis of Online Learning Communities

**Joseph Corneli**
*The Open University, UK*

**Alexander Mikroyannidis**
*The Open University, UK*

## ABSTRACT

*Learning online has significantly evolved over the past decade due to the emergence of Web 2.0 and 3.0 technologies that facilitate social learning in adaptive online environments. The open content movement and the associated techniques of crowdsourcing (i.e. assimilating several small contributions into resources of high quality) have further influenced education on the Web. This chapter investigates the concept of crowdsourcing in education through an analysis of case studies dealing with two open online learning communities, Peer 2 Peer University, and PlanetMath.org. The case studies proceed via an analysis of the various roles played by the individuals involved in each organization. The outcomes of this analysis are used to extract general recommendations for building online communities and applying crowdsourcing techniques in educational contexts.*

## INTRODUCTION

Web 2.0 and 3.0 technologies are transforming the landscape of learning. These technologies enable learners and pedagogues to co-produce learning environments that adapt to the competencies and motivations of each participant. Building these systems online, in the open, system developers and curriculum authors can make use of both high-intensity, high-cost contributions, and a long tail of smaller and less intensive contributions. This process of assimilating many small contributions into resources of high quality – colloquially known as crowdsourcing – is becoming a key aspect of

the development of open online learning platforms. The challenge inherent to such efforts is to capture the surplus value of distributed processes of social engagement in a way that permits reuse and further development.

This chapter rethinks Nonaka and Takeuchi's well-known SECI model of knowledge creation (Nonaka & Takeuchi, 1995), and applies it to two case studies in crowdsourced education. The revisions to the SECI model are two-fold. First, what initially appears to be a simple and intuitive shorthand, obtained by mapping Nonaka and Takeuchi's Socialization/Externalization/Combination/Internalization onto Ken Wilber's I/We/Its/It (Wilber, 1997), upon further reflection leads us to a very different way of thinking about things. And, second, Nishida's philosophy of *basho* (summarized in English by Masao Abe (1988)), which was a noted inspiration for the SECI model, plays an even more central role in our version of the theory.

To put it somewhat colorfully, the "Golden Age" SECI is here updated to make it suitable to the analytical challenges present in our "Modern Age". These challenges include organizations that make significant use of commons-based peer production (CBPP) (Benkler, 2005), organizations without a traditional management structure, and collaborations that cut across organizational boundaries. The focus in our analysis is on the various social roles taken on by the persons involved in such settings.

A point of departure for our new understanding of SECI is the critique found in Engeström's "Innovative learning in work teams: Analyzing cycles of knowledge creation in practice" (Engeström, 1999). Engeström makes a convincing case that "SECI" really doesn't adequately represent a cycle, despite the claims of its initial creators. The I/We/Its/It framework doesn't represent a cycle, either. Rather, we use Wilber's terms to describe a given *social role* in terms of its *constituent actions*. So for example, the role of "being a student" might be described as follows:

*"I go to class, we do a class project, the objects of concern ("Its") are things I can add to my portfolio or work-record; and fundamentally it is all about gaining a skill."*

This simple background story gives us a notion of role, persona, or identity: a role that is defined by its constituent actions, relative a given social context. And here, context is conceived of, after Nishida, as a "shared context in motion" (this is the meaning of the term "*basho*").

Our little story describing the role of a student doesn't have much to do with "knowledge creation" or "epistemic action". Still, now that we have a convenient way to talk about roles, we can move on to talk about how roles can change over time, how new roles come into existence, how different roles can conflict, and so on. It is in this respect that we recover the organizational learning dimensions of the SECI model – not as a byproduct of individual learning cycles, but as a complex of ongoing adjustments to the shared context and the social roles that are enacted therein (Engeström, 2007).

Thus, our concern is with the way a given context creates and is in turn created by its constituent social roles. Using this approach, we will develop a theory of organizational learning that is applicable to contemporary educational communities, possessing all of the complexities of our "Modern Age".

The next section will set the stage by looking broadly at contemporary education and its many stakeholders. We then present a case study centering on an informal course that the first author ran at Peer 2 Peer University in Autumn of 2010[1], followed by a second case study, which applies our model to look at possibilities for organizational change in the community-created online mathematics community, PlanetMath.org.[2] We conclude the chapter with some general recommendations gleaned from reflections on these two case studies.

*Table 1. Sketch of the social roles in a traditional university*

| | |
|---|---|
| **I.** | *I* go to class, *we* do a class project, *the various aspects of which* are things I can add to my portfolio or work-record; and *fundamentally it's all about* gaining a skill. |
| **II.** | *I* lead a class, *we* plan and implement the curriculum, *my work involves* giving lectures and feedback and, more infrequently, meetings with my colleagues; and *fundamentally it's all about* helping my students. |
| **III.** | *I* ask a thought-provoking question, *we* discuss or experiment, *the results* are written up in papers; and *fundamentally it's all about* generating new knowledge. |
| **IV.** | *I* transform ideas into code or policies, *we* collectively manage a body of work, *the pieces* are the components of a functioning system; and *fundamentally it's all about* creating a workflow that works. |
| **V.** | *I* engage in dialog, where I promote a certain position, *we* try to find common ground, *the results of* various interactions and transactions are assembled into strategies; and *fundamentally it's all about* creating a distinctive organizational identity and strong partnerships. |
| **VI.** | *I* endeavor to discern societal needs, *we* work to achieve a rough consensus with a larger body of stakeholders, *the results* describe a certain clearly-defined skill set; and *fundamentally it's all* about knowing the appropriateness and relevance of a certain training process. |

## BACKGROUND: EDUCATION AND ONLINE COMMUNITIES

We begin with a look at how educational communities are built. A traditional university, for example, is populated by students, teachers, researchers, administrators and staff, and possesses a certain legal status by maintaining a relationship with accreditation bodies and government. We get a sense of the dynamics of the university when we look at the actions that comprise these roles (Table 1).

These sketches shouldn't be taken to be definitive, but rather, as paradigmatic. It seems reasonable to say that any social setting that supports actions sufficiently like these is an "educational context". A setting that intersects only a few of them (e.g. an academic publishing house) nevertheless forms part of the broader social context in which education sits.

This leads to the idea that a given educational context can be distributed in space and time in various different ways. Many of the support functions related to infrastructure can be subcontracted or otherwise outsourced. For example, instead of giving lectures in person, an instructor may deliver lectures via podcast.

It is in this distributed setting that Open Educational Resources (OER) arise and become relevant to the future of education. We are concerned in Table 1 with *social* roles, and various social contexts arise to support these as well, ranging from study groups, to tutoring services, to "virtual colleges", to open source software developer communities, to professional associations, all the way through to UNESCO.

In many cases it is not suitable to view such settings as only "ancillary", as they are significant communities in their own right. For example, Wikipedia is more than just an encyclopedia: it is effectively the flagship of a social movement.

### Educational Communities, Online

Two well-known sources of educational content are Connexions[3] and MIT OpenCourseWare[4]. But while both Connexions and MIT OpenCourseWare contribute to the broader commons of OER as production communities, they appear to use commons-based peer production (CBPP) in a limited way. To illustrate the point: at the time of this writing, although thousands of people visit the Connexions website each day, discussion forums are not present on this site. Instead, the (essentially broadcast-based) Connexions blog is the central "community" feature[5].

*Table 2. We are in between several familiar institutions and a couple others that are less familiar.*

| | Solo consumer | Mediated sociality | Social consumer |
|---|---|---|---|
| **Highly modular** | Library | Gutenberg.org 2.0[6] | University |
| **Lightly integrated modules** | Encyclopedia | OER communities | Course |
| **Highly integrated** | Book | Interactive Hypertext | Tutor |

In Table 2, we suggest that consumers of OER exist in a realm in between that of the "solo consumer" and that of the "social consumer"; and that OER resources typically lie in between "highly integrated" systems and "highly modular" systems. This, together with a suitably broad understanding of openness, can make peer production of OER a natural choice.

In the next two sections of the chapter, we will examine two distinct educational communities, Peer 2 Peer University (P2PU), and PlanetMath.org. The former is building a social platform, together with a collection of best practices related to running peer-based courses online and a collection of course materials from previous courses. The latter is building a mathematics encyclopedia with integrated discussion forums, and, at present, has essentially nothing to do with courses or course materials per se.

We can imagine a team-up in which PlanetMath provides content and supports learner interactions, whereas P2PU provides training training to course organizers in the important non-mathematical skills for running an effective course, as well as a certification layer for course participants. The following sections will examine these two cases using an approach similar to the role-based analysis of Table 1, but they will go into much greater depth.

## P2PU CASE STUDY: "ONLINE BOOK CLUBS FOR OER"

### Overview, Objectives, Challenges

This case study is based on the experiences of the present first author as the facilitator of an online course called "DIY Math" that ran through the Peer 2 Peer University in Autumn of 2010. The interactions in and surrounding this course provide a lens on P2PU as a whole.

We will now present some background information on P2PU and the design of DIY Math. From the P2PU website:

*The Peer 2 Peer University is a grassroots open education project that organizes learning outside of institutional walls and gives learners recognition for their achievements. P2PU creates a model for lifelong learning alongside traditional formal higher education. Leveraging the internet and educational materials openly available online, P2PU enables high-quality low-cost education opportunities.*[7]

The Shuttleworth Foundation, who sponsored P2PU early on with a $30K fellowship, provides the following description of the organization:

*The Peer 2 Peer University (P2PU) is an online community of open study groups for short university-level courses. Think of it as online book clubs for open educational resources. The P2PU helps you navigate the wealth of open education materials that are out there, creates small groups of motivated learners, and supports the design and facilitation of courses. Students and tutors get recognition for their work, and we are building pathways to formal credit as well.*[8]

Although P2PU has only been online since 2009, they have gathered significant media attention and interest. They describe themselves as an

online community of about 1000 persons. Many of P2PU's core volunteers are also affiliated with other organizations in the open online education space. The P2PU approach is to be "open" to nearly any constructive form of participation. They are in the process of making their "horizontal governance" structure more clear, at the same time as they pursue formal incorporation and non-profit status. They are presently experimenting with a range of learning and communication technologies. They were enthusiastic about adding a mathematical course to their range of offerings.

The DIY Math course itself was designed to deal with the question *how should we build a course that supports both independent and peer-based mathematics learning?* By being expressly open to "mathematics learners at all levels", DIY Math followed a very atypical approach to the teaching and learning of mathematics. The rationale behind this was that learners would eventually self-organize a support system. Accordingly, the syllabus did not include specific mathematics topics or exercises, but rather, certain general suggestions regarding collaboration:

- be ready to introduce yourself and your interests in the mailing list by the time the course starts;
- reply to at least one other person's self-introduction to say how it relates to your own interests;
- come up with some candidate discussion guidelines or objectives;
- update the group when you start looking at a new mathematical resource;
- give a review saying whether you found that particular resource helpful or not, and why;
- post short summaries of any study strategies you're using;
- post reviews of your strategies;
- identify one or more study buddies who are interested in topics similar to the ones you're most interested in;
- post in response to one of the two prompts that follow: "Tell us about something you learned."; and/or "Tell us about something you're having difficulty with."

Twenty-two people initially signed up for the course, and their applications alone were enough to generate some useful reflections. In particular, they provided a first impression of the mathematical interests of the would-be participants. Despite the initial show of (wide-ranging) interest, less than half of these people made it past the hurdle of "self introductions", which were to take place in the course's Google Group.[9]

By the second week, things had already gotten pretty quiet. Although the essence of "DIY Math" had been made reasonably clear to the participants, this did not translate into anything resembling a serious commitment. To generalize from this experience:

1. *When organizing an event or setting up a context for any given social activity, it is a really good idea to ask people what they would like to do there*; and
2. *It is equally important to get the participants to commit to follow through on actually doing*
3. *what they said they are interested in* (if their commitment is insufficient, the description of the activity should be revised and commitments renegotiated accordingly).

The experience with DIY Math shows that the idea of self-organization alone will not create a successful peer-to-peer learning environment. In a traditional educational setting, there are a variety of factors (e.g. money, credentialization, informally enforced norms) that could help create a sense of commitment on the part of learners: by default, these are wholly missing in informal learning.

In P2PU at present, a lot of the "pull" comes from facilitators who not only decide what courses to run, but who also are charged with keeping the peer learners engaged, and contributing to a body

of knowledge about how this can work best. In this organization that places a strong value on non-hierarchical peer relationships, at present, the importance of the complex role of course facilitator is "not to be under-estimated".

## Role-Based Analysis

Tables 3-7 present several different roles associated with DIY Math and P2PU more generally. These are:

- The role of an an "ideal" participant in the DIY Math course (i.e. based on how things were supposed to work, according to the syllabus);
- The role of a more realistically-conceptualized participant in the DIY Math course (how things *actually* worked for most people);
- The role of a facilitator at P2PU;
- The possible future role of a peer learner in a structured "Short Calculus" course taught at P2PU;
- The possible future role of an "arbitrary participant" in P2PU where the organizational structure has become flatter.

## Lessons Learned

The flattening of roles in Table 7 is potentially surprising. The insight embodied in that gesture is as follows.

If P2PU was taking an ongoing survey of the "wished for" course topics, a future course organizer would presumably be able to create courses specifically tailored to the interests of pre-self-selected participants. Alternatively, interests could simply be listed ("social network style") on user profile pages and aggregated in an intuitive way. Levels of commitment could similarly be specified in advance, ranging from "I'd like to put 1 hour a week on this topic" to "I'm available to work on this full time." Detailed qualitative aspects of commitments could also be specified (e.g. "I'm willing to answer questions about Calculus but keep in mind I haven't taken it for a few years").

The key point is that the system could then be set up so that courses only would only run when sufficient interest had gathered. This design would use the idea of "shared context in motion" to help relationships form organically, and to emphasize the importance of appropriate commitments for building trust.

Another lesson is that a participant in a structured course like Short Calculus (Table 6) might benefit from the existence of an unstructured support system, something like DIY Math. This approach is consistent with the idea that a peer-based community doesn't easily arrange itself into explicitly delineated and wholly "visible" structures, but may instead have a lot going on in the background (Engeström, 2007).

Recalling the vision of "online book clubs for open educational resources", the possibility that a facilitator need only be very slightly involved again suggests itself. There appears to be a certain degree of trade-off between the time and energy spent preparing course materials, and the time and energy spent facilitating the course. (From the point of view of Table 1, part II, this is the difference between what "we" do together as

*Table 3. The role of an "ideal" participant in DIY Math course*

| | |
|---|---|
| I | say what I want to study |
| We | talk about difficulties and successes |
| Its | discussions on a shared mailing list |
| It | helps me learn mathematics (and improve my skills at being a self-directed and peer-to-peer learner) |

*Table 4. The role of a more realistically-conceptualized participant in the DIY Math course*

| | |
|---|---|
| I | try to figure out what to study |
| We | sometimes give or get advice that isn't always so helpful (and most of it isn't for me, anyway) |
| Its | a bunch of good intentions that lead nowhere |
| It | confirms my sense of the difficulty of learning anything in a self-directed fashion (and the difficulty of mathematics in particular) |

*Table 5. The current role of a facilitator at P2PU*

| | |
|---|---|
| I | come up with a course I'd like to facilitate, and then facilitate it |
| We | discuss ideas about how our courses might work and what "facilitation" means (e.g. as opposed to "teaching") |
| Its | discussions on a community mailing list and other settings (including discussions with participants in the course as it runs) |
| It | helps me improve my skills at a course designer and facilitator (and it's fun talking about and practicing this stuff!) |

*Table 6. The possible future role of a peer learner in a structured "Short Calculus" course at P2PU*

| | |
|---|---|
| I | work on calculus problems from the syllabus and ask questions in an appropriate venue when I get stuck |
| We | talk about difficulties and successes and examples |
| Its | discussions on one or more shared mailing lists or forums |
| It | helps me learn calculus (and develop some good study habits along the way) |

*Table 7. The possible future role of an "arbitrary participant" in P2PU*

| | |
|---|---|
| I | describe what I'd like to learn or teach |
| We | constitute a class when we have gathered a enough interested peers with the right mix of skills; in the mean time, and in general, we constitute a broader learning community |
| Its | a marketplace of interests, skills, and ideas on the one hand, and efforts, attempts, and assistance on the other |
| It | helps me learn what I want to learn and have fun in the process |

teachers, and what "I" do as a teacher.) It is conceivable that the best facilitator would not be an expert in the course's subject matter, but an expert in peer-supported learning per se.

In Winter 2011, the first author facilitated three more courses at P2PU, with mixed results, which nevertheless appear to strongly support the perspectives outlined above. One useful outcome of these experiences is that we have significantly improved our theory of peer-to-peer learning (summarized in the section entitled "Paragogy", below).[10]

## PLANETMATH CASE STUDY: "MATH FOR THE PEOPLE, BY THE PEOPLE"

### Overview, Objectives, Challenges

The scope of this case study is quite different from the one in the previous Section, since here we will look in overview at the last 10 years of PlanetMath.org, instead of the last few months.

PlanetMath came into being as the core of the work done by Aaron Krowne for his Masters degree at Virgina Tech (Krowne, 2003). On

PlanetMath, one finds the following statement by Krowne:

*The idea for the project was hatched by [Nathan] Egge, sometime around fall 2000, in response to the unfortunate removal of the great resource, "Eric Weisstein's World of Math" (or "MathWorld") from the internet. This incident created a void for a useful, comprehensive math encyclopedia freely available online, which we wanted to fill as quickly as possible. So Nathan and Aaron began brainstorming the concept and working out many of the problems inherent in a system that would do in real-time what had been static on MathWorld. We also wanted to make certain that the users of PlanetMath would never have to worry about the removal of the content they had contributed in favour of commercial sale.*[11]

Since its inception in the year 2000, over 11K encyclopedia articles have been contributed to PlanetMath, and over 14K posts have been made in the discussion forums. In recent years, the website has received 12-20K hits per day, the larger number when school is in session. It is worth noting that PlanetMath has many "competitors", the most obvious being Wikipedia, which went online in 2001, and also MathWorld, which has been *back* online since 2001. It is also worth noting that in fact a considerable amount of content has been *shared* in both directions between PlanetMath and Wikipedia under the terms of their common license, so in this sense they can be seen more as "collaborators" than as competitors. Another site that could be seen to compete-while-collaborating with PlanetMath is MathOverflow.net, a question and answer site hosted on StackExchange, and which, again, uses the Creative Commons Attribution-ShareAlike (CC-By-SA) license for its content.

At this point, while PlanetMath's content collection continues to grow, the growing number of competitors of various sorts, as well as growing opportunities for collaboration, serves to suggest that infrastructural development will be vital if PlanetMath is to have any significant success in its "next ten years".

Luckily, over the course of the past decade, there has also been a significant maturation of tools for dealing with mathematics, and a collection of such tools, developed by the KWARC research group at Jacobs University, in Bremen, Germany, now form the basis for a new software platform for PlanetMath that we call "Planetary" (David, Ginev, Kohlhase & Corneli, 2010). This technological leg up gives us a realistic opportunity to ask *what should PlanetMath develop into?*

For example, we could inject P2PU-like (or P2PU-hosted) courses into PlanetMath; assignments might include "write or improve a PlanetMath article" or "post questions and answers in the forum". PlanetMath could also draw more on other resources created elsewhere, as well as do more to share or mash up its resources and services with others (e.g. Wikipedia and MathOverflow.net; also with the popular mathematics preprint server, ArXiv).

All of these things should happen, and they will certainly change the context at PlanetMath. However, it is not entirely clear that such improvements will directly change the *roles* of PlanetMath users. By contrast, introducing *problem sets* into PlanetMath would create a whole new set of roles centered on creating, solving, and marking problem sets online. The persons engaged with such activities might be mathematics learners, volunteers, or paid tutors.

There are certainly other challenges we could take up, and many questions to answer along the way. In order to do this effectively, PlanetMath should round out its "open content" and "open source" communities with improved methodologies for doing *open governance*. Some important issues to decide will be our approach to *open data* (just what data will be open?) and more generally how PlanetMath will relate to the emerging field of *open science*. Our own involvement over the next couple of years will focus on the issue

of problem sets, but the other ideas mentioned here are likely to find other champions within the community.

## Role-Based Analysis

Tables 8-13 present several different roles associated with PlanetMath. These are:

- The role of a contributor to the PlanetMath encyclopedia
- Possible future role of a contributor to the PlanetMath's collection of problems.
- Possible future role of a person using PlanetMath as a place to solve problems
- Possible future role of a tutor on PlanetMath
- Possible future role of a "benevolent technocrat" on PlanetMath
- Possible future role of a "citizen programmer/hacktivist" on PlanetMath

Note that a "casual browser" or someone who only posts a few questions in the forum will have a profile that's very different from any of these. In particular, such a user's sense of "We" will likely have to do mainly with off-site relationships.

In light of this, it would be tempting to imagine that "producer" and "consumer" roles are quite distinct. But at least in some parts of PlanetMath, they tend to be closely combined. For example, one must actively engage with problems in order to solve them, and a consumer of problems tends to be a producer of problem-solutions.

Is a problem contributor (Table 9) significantly different from a contributor to the encyclopedia (Table 8)? At the very least, different motivations are likely to be near the surface (e.g. "altruistic" motivations centered on helping others learn; or perhaps an interest in the way the organization as a whole learns), but it also seems that the style of working is very different (e.g. creating a good problem, in this context, has more to do with connections between system objects than it has to do with "exposition").

## Lessons Learned

If there is one clear lesson from the past 10 years of PlanetMath, it is that there is no shortage of great ideas out there. Unfortunately, there *is* a shortage of idea-implementers. The difference between Table 12 and Table 13 is meant to provide a view on that. These two roles differ only rather subtly, but the main idea is that we could in theory have many "citizen programmers", whereas at any given point in time, we are likely to have only a few "benevolent technocrats".

By building much of the new Planetary System in the form of modular extensions to the popular open source Vanilla Forums, we hope to make Planetary itself relatively easy to extend. To actually get people involved in the programming effort may require us to go quite a bit further, possibly even so far as to create a "PlanetComputing" where the Planetary System's code can be discussed and improved.

We hope that by making the development process more visible within future implementations of PlanetMath – and easier to get involved with – that we will be able to help people translate "ideas" into "incentives", and channel user input to a variety of increasingly useful ends. Some things that are difficult or impossible to achieve now should be fairly easy to deal with once more people are involved in the development effort. This will require careful ongoing analysis and design of social roles and contexts.

# GENERAL RECOMMENDATIONS FOR BUILDING COMMUNITIES AND CROWDSOURCING EDUCATION

## Comparing Crowdsourced and Traditional Education

One important question is to ask what differences occur between Tables 3-13 and Table 1, and in particular, whether crowdsourced

*Table 8. The role of a contributor to the PlanetMath encyclopedia*

| | |
|---|---|
| I | write about things I'm interested in, in the form of encyclopedia articles |
| We | give each other feedback on the things that have been written so far |
| Its | a collection of articles, forum posts, and metadata |
| It | helps me learn mathematics (by giving me the chance to practice expressing myself clearly) |

*Table 9. Possible future role of a contributor to the PlanetMath's collection of problems*

| | |
|---|---|
| I | write or find and contribute problems that link together with other problems and with encyclopedia articles |
| We | help each other determine the context that is best-suited to a given problem |
| Its | a collection of problems and semantic links |
| It | helps me share mathematical understanding with others and helps me understand mathematics more deeply myself |

*Table 10. Possible future role of a person using PlanetMath as a place to solve problems*

| | |
|---|---|
| I | solve problems online and get help from encyclopedia articles, peers, or, if I want, a tutor |
| We | turn to each other for help when we see we have common interests |
| Its | a collection of exercises, articles, solutions, and metadata that's intended to support independent and peer-based learning |
| It | helps me learn mathematics much as I would in a traditional classroom (but I can go at my own pace and pick my own topics) |

*Table 11. Possible future role of a tutor on PlanetMath*

| | |
|---|---|
| I | get paid to answer questions |
| We | work together to create the best collection of resources for helping tutors answer questions (and helping learners work on their own) |
| Its | a collection of previous tutoring sessions, augmented with annotations and links created by us or others |
| It | lets me use my mathematical proficiency to make money and help other people |

*Table 12. Possible future role of a "benevolent technocrat" on PlanetMath*

| | |
|---|---|
| I | review usage data from the system, integrate this with feedback from the community, and implement systems that serve their interests |
| We | meet along the boundary between content and code |
| Its | a collection of policies and programs maintained on behalf of the user community |
| It | keeps the site alive (and, thanks to me, growing) |

*Table 13. Possible future role of a "citizen programmer/hacktivist" on PlanetMath*

| | |
|---|---|
| I | contribute to code development as part of my regular form of interaction with the site and the corpus |
| We | make decisions horizontally and have engineered out systems and policies so that no one person has much more power than any other (in particular, we've endeavored to widen out organizational bottlenecks) |
| Its | a collection of policies embodied in code |
| It | not only keeps our site running, but allows us to make further inroads into online education more generally |

education is very different from traditional education or not.

The "student" and "teacher" roles are well represented in the model of crowdsourced education that we've developed. "Research" is *not* explicitly mentioned in any of our tables, but it certainly takes place, i.e. both research *about* crowdsourcing and peer-to-peer education, and also crowdsourced, peer-based, research on other topics, e.g. "Density Hales-Jewett and Moser numbers" by D.H.J. Polymath.[12] Building better support for this kind of massive collaboration – or even just better support for more tame computer-mediated research collaborations – is on PlanetMath's equally massive todo list. "Developer/administrator" roles are represented in Table 12, and an interesting blended "developer/advocate" role is described in Table 12.

In short, it seems that the only role from Table 1 that we haven't encountered in our analysis of P2PU and PlanetMath is the "accreditation body" role. Of course, it would be somewhat rare to find such persons embedded in a traditional university, since accreditation is importantly an "outside" role. P2PU has some innovative ideas about "peer assessment" and other strategies for measuring when learning is taking place, but these are quite a ways off from offering actual credits or diplomas.[13] They are also considering some team-ups with traditional institutions, where the outside institution grants credit to their enrolled students for work on P2PU.

In the case of PlanetMath, sufficiently rich and robust online problem sets should provide a clear sense of a learner's current state of knowledge; such measurements may in some cases be substitutable for a degree. At least according to our sketch in Table 1, it all depends on "knowing the appropriateness and relevance" of the training process. In some cases, this could be measured by learner performance on outside exams (e.g. AP tests, GRE subject tests, or perhaps even the Mathematical Tripos).

It would therefore appear that crowdsourced educational models at least have a chance of being as complete as the traditional model. Do they come with any additional benefits or constraints? The idea of a "a marketplace of interests, skills, and ideas" from Table 7 seems to have no ready correspondent in the world of traditional universities, except perhaps in a limited form, in the course catalog. At the same time, despite the broad popularity of social networks and the integration of some social networking functionality in both P2PU and PlanetMath, social networking on these sites is currently quite primative (simple questions like "find me a PlanetMath user who is interested in pedagogy" don't have easy answers).

Another major difference is in the issues surrounding commitment. Whereas students in traditional universities are presumed to be motivated by the prospect of earning a degree or certification, in informal education, a learner's prospects are entirely related to the skills they acquire, and to any enjoyment that comes from the learning process itself. If people need to be cajoled into committing, that isn't a terribly good sign. It seems it would be better if the learning environment itself facilitated involvement from people in the ways they feel suits them best. Perhaps incentives don't need to be created so much as "exposed" or "acknowledged".

## General Recommendations

Different sites seem to exist precisely so that different modes of engagement will be supported. They certainly shouldn't be homogenized, and probably it's not even sensible to ask for them to be "rationalized". Rather, it seems important to design for a variety of different modes of engagement and patterns of use.

Because of the way we've framed the analysis, we've seen that there is a social dimension to every resource. These don't always have to be "open" in every sense to be successful. However,

it seems likely that one way to open things up more, when desired, is to continue to do analyses of the kind we've done here: every organization can be mapped in this way, and can be examined for its potential *to support learning*.

It is useful to recall that a social context is defined by a variety of roles, and that roles often cross-organizational boundaries. Further, from the examples we examined, it appears that mixed approaches (a social layer *plus* preexisting resources; or, independent learning *plus* tutoring) have particularly strong potential.

At the same time, we should remark that a certain degree of cohesion in the learning platform ought to help make the *sharedness* of context more clearly felt. The question "how much cohesion is good?" seems to depend on the two factors most relevant to CBPP, integration, and modularity. Depending on what seems useful for the purpose at hand, a group of learners might be organized as a closed and seconded group, or as an open group embedded within a broader commons.

Licensing is one way in which groups become cohesive (and keep others out). Initiatives like MIT Open Courseware and OpenLearn[14] use a Creative Commons Attribution-NonCommercial-ShareAlike 2.0 Licence; Wikipedia, PlanetMath, and P2PU use a Creative Commons Attribution-ShareAlike 2.0, and Connexions uses a Creative Commons Attribution 3.0 license. Licensing can powerfully change the way people relate to resources, especially when it comes to future re-use and/or modification.

An educational community may or may not seek to become sustainable. Sustainability could apply to features like growth, innovation, longevity, communication, and more, and it seems clear that a diversity of approaches must combine gracefully if prospects of sustainability are to have much hope. The style of analysis we have employed could help an organization define and create new roles to adapt to a shifting context.

## Paragogy

One outcome of thinking about how to improve on the DIY Math course while building on the strengths of the P2PU organization as a whole is a new theory of peer-based teaching-and-learning, termed "paragogy" (Corneli & Danoff, 2011). Paragogy uses the "five principles of andragogy" stated by Malcolm Knowles as a jumping off point (Knowles, 1968, 1980). In super-succinct form, Knowles's five principles are: (1) that adults are self-directed learners, (2) that adult learners bring a wealth of experience to the educational setting, (3) that adults enter educational settings ready to learn, (4) that adults are problem-centered in their learning, and (5) that adults are best motivated by internal factors. A useful review and critique that goes beyond the soundbytes above is given by Laurie C. Blondy (2007). The five paragogical principles are:

1. *Context as a decentered center.* For learning design in a peer-to-peer context, understanding the learner's self-concept – in particular, whether they see themselves as self-directed or not – may be less important than understanding the concept of shared context in motion.
2. *Meta-learning as a font of knowledge.* We all have a lot to learn about learning.
3. *Peers are equals, but different.* The learner mustn't seek only to confirm what they already know, and must therefor confront and make sense of difference as part of the learning experience.
4. *Learning is distributed and nonlinear.* Sidetracking is OK, but dissipation isn't likely to work. Part of paragogy is learning how to find one's way around a given social field.
5. *Realize the dream, then wake up!* Paragogy is the art of fulfilling motivations when this is possible, and then going on to the next thing.

Paragogy can be fruitfully compared with another andragogy spin-off, heutagogy, a theory of self-directed learning (Hase & Kenyon, 2000). Because of its focus on the entire learning context, paragogy appears to intersect andragogy at 90 degrees, whereas heutagogy, with its focus centered on the learner, is 180 degrees away from paragogy. However, these theories do not seem to intrinsically conflict with one another, even though they offer very different views on education.

We feel that paragogy provides a useful philosophy for the advocate and practitioner of crowdsourced education, and that, together with role-based analysis proposed in this paper, it can be valuable addition to the world of OER and open online education. More generally, paragogy and its concept of the peer production of the learning context can open a new window on the ideas of organizational learning coming from the classical SECI model.

## CONCLUSION AND OUTLOOK

The chapter describes the various social roles of the individuals involved with P2PU and PlanetMath.org, and envisions future roles that could be created at these organizations. We hope that our analysis will help inform the relevant design, implementation, and governance decisions.

In addition, we compared crowdsourced and traditional education and found that the crowdsourcing model has room for most, if not all, of the roles found in the traditional setting, accreditation and assessment being a key area where there are no definitive answers as yet. It appears that the crowdsourced model can offer some additional richness, thanks to the role played by social networking tools, though social networking that works well for education is still in development. Perhaps new approaches here will help understand the various styles of commitment that manifest schematically in the "long tail" phenomenon that fuels crowdsourcing.

We expect that the role-based style of analysis we employed throughout this chapter, and the idea of paragogy, introduced above, can be applied fruitfully in both offline and online contexts. We look forward to developing these techniques further in our research, teaching, and development work, and invite the OER community at large to use and improve them (as always!).

## KEY TERMS AND DEFINITIONS

**Andragogy:** Andragogy refers to a learning strategy focused on engaging and motivating adult learners. Andragogy makes the following assumptions about learning design: (i) adults need to know

why they need to learn something, (ii) adults need to learn experientially, (iii) adults approach learning as problem-solving, and (iv) adults learn best when the topic is of immediate value (Knowles, 1968, 1980).

**Crowdsourcing Education:** Crowdsourcing is commonly known as the process of assimilating many small contributions into resources of high quality. Crowdsourcing has emerged as a vital aspect of education on the web, as it promotes the openness and reusability of online educational resources contributed by communities of learners and educators.

**Heutagogy:** Heutagogy is a theory of self-determined and self-directed learning (Hase & Kenyon, 2000). Heutagogy builds on humanistic theories described in the 1950s and adapts them to the needs of today's learners, particularly targeting the development of individual capability.

**Online Community:** An online community is a community the members of which use online tools and services in order to engage into social interactions. These tools and services vary from instant messaging (IM) tools and forums to social networks. The members of these communities normally share common interests and goals and use the web in order to communicate with their peers, participate into discussions, exchange ideas, and work collaboratively towards a common goal.

**Paragogy:** Paragogy is a theory of peer-based learning, built on top of the following principles: (i) context is a decentered center, (ii) meta-learning is a font of knowledge, (iii) peers are equals, but different, (iv) learning is distributed and nonlinear, and (v) realize the dream, then wake up! (Corneli & Danoff, 2011).

**Peer-Based Learning:** Peer-based learning is driven by peer-mentoring instead of a central mentoring authority. Learners are mentoring each other and engage into a collaborative learning journey. A peer-based course functions similarly to a book club, whose members take turns into recommending books that are studied by the group, followed by an exchange of reviews and opinions.

**SECI Model:** SECI stands for Socialisation, Externalisation, Combination, and Internalisation. These are the 4 phases of knowledge engineering according to (Nonaka et al., 2000, Nonaka et al., 2003). More specifically, Nonaka and Toyama suggest that knowledge is created as people interact in a shared context, through a process that can be broken up into repeated phases. The SECI model takes into account the range of different behaviours and modes of interaction, involving activities that are both individual and collective, and forms of engagement that are embodied or virtual.

# The PlanetMath Encyclopedia

Joseph Corneli
Knowledge Media Institute
The Open University
Milton Keynes, UK
j.a.corneli@open.ac.uk

**Abstract**

The history of PlanetMath.org is discussed, tracing its inception, stabilization, and some defining challenges. Research and outreach efforts that have been conducted in the course of work on the PlanetMath project are reviewed, and the scope and reach of the resource are discussed. Recent developments are indicated briefly. Some remarks evaluating PlanetMath's trajectory and content conclude the paper.

**Keywords:** online communities, mathematics, collaboration, encyclopedias, Commons-Based Peer Production, PlanetMath

## 1 Introduction

From PlanetMath.org's landing page[1]:

> *PlanetMath is a virtual community which aims to help make mathematical knowledge more accessible. PlanetMath's content is created collaboratively: the main feature is the mathematics encyclopedia with entries written and reviewed by members.*

This short paper describes the history of the PlanetMath encyclopedia. The history of this resource cannot be easily separated from a history of the PlanetMath community and the technology behind the site, though the presentation here is not especially technical. The reader who is interested in a succinct overview of the *current* characteristics of the encyclopedia will find what they seek in Sections 6 (quantitative aspects) and 8 (qualitative aspects).

## 2 Beginnings

The early history of PlanetMath is wrapped up with that of the similarly-named website, MathWorld.[2]

Eric Weisstein began collecting the material now found in MathWorld as a high school student, and continued the project as a college student in the late 1980s. "Eric's Treasure Trove of Mathematics," went online in 1995, when Weisstein was a graduate student in astronomy at the California Institute of Technology.[3] In November 1998, Weisstein made a deal with the CRC Press to publish his encyclopedia in book format, as the *CRC Concise Encyclopedia of Mathematics*. One year later, Weisstein accepted the position of encyclopedist at Wolfram Research, Inc., and the renamed "MathWorld" site was unveiled in December 1999.[4] In March 2000, CRC Press sued Weisstein and Wolfram Research for copyright violation, forcing MathWorld off of the internet.[5]

[4] `http://en.wikipedia.org/wiki/Eric_W._Weisstein`

[5] 57 U.S.P.Q.2d 1220 (C.D. Ill. 2000)

In the words of Eric Weisstein: "if you ever assemble a body of knowledge that you want to share with others, you don't want to go through what I have just gone through."[6] So it came to pass that in the Fall of 2000, Nathan Egge and Aaron Krowne, at that time both undergraduates at Virginia Tech, came up with the idea for PlanetMath: a collaboratively created mathematics reference work that would have resistance to copyright threats built in, in the form of an open content license. By the summer of 2001, the basic infrastructure for creating an encyclopedia was complete, and a fledgling community had grown up around the resource.

The CRC lawsuit was settled for an undisclosed sum in late 2001, and on November 6, 2001, MathWorld returned to the internet.[7] But in the mean time, a new online community had been born – with some very different principles and practices. Whereas MathWorld's terms of use disallow archival copies, PlanetMath regularly publishes snapshots of the content for download. Moreover, users are permitted (and, indeed, encouraged) to copy, mirror, redistribute, print, remix, and reuse PlanetMath content for commercial or any other purpose – so long as all such works are published under the same license as PlanetMath, granting downstream users the same rights.

## 3 Stabilization

The key reference for PlanetMath is Aaron Krowne's 2003 Master's Thesis, written at Virginia Tech [6] under the supervision of Ed Fox. In this thesis, Krowne describes how the early design and development of the site benefited from continuous feedback in the #math IRC channel on Undernet.[8] He also details the key technical and community features of the site as they developed in this period:

- A state-of-the-art system for displaying mathematical notation on the web, starting from LaTeX sources.
- A flexible authority model that can support both wiki-style articles (that anyone can edit), and a more academic style, where articles are owned by one person, who may, if they wish, grant co-authorship permissions to chosen others, and who must respond to separate commentary from peer reviewers (cf. [7]).
- A discussion forum attached to every encyclopedia article, which helps give the resource a "pedagogical slant".
- An autolinking service that helps integrate content into the site, by enabling authors to focus on the contents of one article at a time.
- Workflow built around corrections and watches, including a feature whereby articles are "orphaned" if a correction is not responded to after a given period of time.
- A scoring feature that provides a rough estimate of how much value each user has contributed to the site.

In 2003, PlanetMath incorporated, and in 2005, obtained non-profit status, so that it could accept tax-deductible donations (in the US). Together with a small stream of ad revenue, this has covered hosting and other maintenance costs.

[6] See Footnote 3.

[8] `irc://irc.undernet.org/math`

# 4 Pushing the limits

In 2003, the present author was enrolled as a graduate student in mathematics at the University of Texas in Austin, and in possession of a large and growing personal collection of very tersely-written definitions and proofs relevant to the department's prelim exams.[9] In fact, this work had as much to do with the tradition of computer mathematics in the air in Austin (QED, Maxima, ACL2, AM) as it had to with exams. A representative example:

(lebesgue outer measure: fact: lebesgue outer measure is infimum of lebesgue outer measures of open supersets)

1: $X \subset \mathbf{R}^n$
2: $L = \{O \circledcirc \mathbf{R}^n : O \supset X\}$
3: $|X|_e = \inf_{O \in L}(\{|O|_e\})$

After discovering PlanetMath and striking up a correspondence with Krowne, one night we uploaded the contents of the "Austin Problems in Mathematics – Cross-Index" (styled APM-$\xi$) into the PlanetMath encyclopedia as world-editable "seed entries". This turned out to be a first-rate disaster.[10]

The primary complaints from community members were:

(1) the entries could not be understood without reading an accompanying FAQ;

(2) a casual visitor to the PlanetMath website might get the wrong impression about the nature of the encyclopedia when looking at "apmxi" entries; and,

(3) nearly 600 entries had been introduced into PlanetMath by the site's administrator in one big batch, circumventing, at least in outward appearances, the site's usual model of careful review and collaborative editing of entries.

Subsequent to a poll, it was decided that the apmxi entries would be "orphaned", and any that were not adopted by community members after a week would be deleted from the encyclopedia. This was the fate that befell most.

The event was a defining moment in the history of PlanetMath. In the first place, it was a testament to the strength of the community's norms. Secondly, it showed that the specific affordances of computers, e.g. for mass processing of data, or for dealing with hypertextual complexity associated with alternate related treatments of a given topic, needed to be tempered to work well for the *people* involved. These issues would set much of the research and development agenda around PlanetMath for the following decade.

# 5 Research, outreach, and some critiques

In 2005, several established PlanetMath contributors met in person at a Symposium on *Free Culture and the Digital Library* at Emory University, where Krowne was then based. Contributed papers looked at

- an adaptation of PlanetMath's software for collaborative creation of course notes in a graduate course on ordinary differential equations [10];
- experiments with a novel hypertext system based on the idea that everything is annotatable [1]; and,

[9] `http://metameso.org/~joe/math/Xi.pdf`
[10] `http://wiki.planetmath.org/cgi-bin/wiki.pl/one_week_in_october`

- the dynamic tension between the non-copyrightability of ideas, and the necessity of conveying ideas in copyrightable expressions, and the ramifications for mathematics [12].

These reflections on copyright (and copyleft) were subsequently expanded in an article for *First Monday*, which looked at the drawbacks of current copyleft licenses, particularly "license lock" [8].

We presented talks about PlanetMath in the *Math on the web pavilion* at two Joint Mathematics Meetings (San Antonio, 2006[11]; New Orleans, 2007[12]), and in a session on *The Role of Open Source Math Projects in the Mathematics Community* at MathFest (Madison, 2008)[13]; and at more specialized workshops: *The Evolution of Mathematical Communication in the Age of Digital Libraries* (Minneapolis, 2006)[14], and *Mathematical Knowledge Management: Sustainability, Scalability and Interoperability* (Halifax, 2007)[15].

We also made efforts to create a print version of the PlanetMath encyclopedia (retitled the "Free Encyclopedia of Mathematics"). The 2004 attempt, in two volumes[16], and a 2005 attempt in one much nicer-looking volume[17], thanks to Ross Moore's contribution of `multinclude.sty` and other tweaks.[18] Still, the resulting 1971 page PDF was more a proof of concept than a printer's proof.

On the development side, PlanetMath was thrice supported by Google's Summer of Code (2006–2008). The best outcome of this was that PlanetMath's autolinking subsystem was turned into a modular piece of code, NNexus[19], as written up in [5]. PlanetMath's software improved further under contract with Springer, pursuant to the creation of StatProb.com.[20] PlanetMath's sister site PlanetPhysics.org[21] is currently in the process of switching over to this platform, termed Noosphere 1.5.

However, the development effort wasn't particularly able to keep pace with the feature requests generated by the user community.[22] Nor did the Noosphere codebase present a particularly compelling resource for capable computer mathematics developers like Claus Zinn [14] and Christoph Lange [9], to jump into and improve. Zinn wrote:

> *The rapid growth of math resources on the web, which is further pushed by wiki-based communities, is both a threat and an opportunity for intelligent math learning environments [...] If we could harness the collaborative authoring process and encourage and guide wiki authors to continually provide content and metadata, then intelligent services could unleash their true potential.*

## 6 Scope and reach

At the time of this writing, PlanetMath contains 8945 entries, dealing with 15655 concepts. 298 people have contributed an entry in the encyclopedia, and 2742 have contributed something (perhaps just one forum post).

[11] `www.jointmathematicsmeetings.org/meetings/national/jmm/san-prog.pdf`

[20] `http://statprob.com`
[21] `http://planetphysics.org`
[22] `http://wiki.planetmath.org/cgi-bin/wiki.pl/Feature_Requests`

Out of these, an exceptional group of 24 authors have produced more than 100 encyclopedia articles apiece. Their contributions comprise 74% of the total number of articles. About 71% of this core group joined before 2004 (in the "early days" for the site).

130 users have a score of 1000 points or more, which would correspond to contributing 10 or more new encyclopedia articles, but actually, a significant fraction of this value has been contributed through things like corrections, revisions to existing objects, and posting in the forums. All told, this group has contributed 96% of the total number of articles. About 58% of this group joined before 2004.

According to Alexa.com, PlanetMath.org is currently the 165,011$^{\text{th}}$ most popular website in the world, comparable to the website of the Mathematical Association of America[23] (119,267$^{\text{th}}$), or relative newcomer MathOverflow.net[24] (184,818$^{\text{th}}$).

A far cry from competing with Wikipedia, but in fact we like to think of the two projects as mutually supporting. PlanetMath content is reused under the terms of the shared CC-By-SA license in hundreds of Wikipedia articles, and cited in over 1500.

## 7 A new era

In 2010, a new project to completely rebuild PlanetMath's software began. *Planetary* is based at Jacobs University, Bremen, and led by Michael Kohlhase, with major contributions from most members of his research group (along with the present author).[25] The Planetary system is described in [4]. Planetary is considerably easier to extend than Noosphere: it is currently comprised of around 20 plugins for the popular open source platform, Vanilla Forums[26], many of which integrate sophisticated software tools previously developed by the KWARC group. Notably, the system now includes support for semantic authoring and flexible metadata interaction, addressing the critiques mentioned in Section 5.

2011 will see the publication of a book chapter discussing the future use of PlanetMath as the core of a problem-based learning system [2], the focus of the author's doctoral studies [3]. With this as a basis for a showcase of innovative uses for the PlanetMath content, and with a well-documented and easy to extend software platform supporting the system, we hope to see PlanetMath become a central integration platform for free software projects working with freely licensed math on the web.

## 8 Conclusion

PlanetMath has been successful as an online community: the software stabilized early on and has required little upkeep, while the site has continued to grow. However, there has been a danger that with the software system running more or less on "autopilot", new features would not be developed. With any luck, this threat is in the process of being eliminated, heralding in the opportunity to build one or more "new" online communities in close relationship to PlanetMath (e.g. a developer community working on sophisticated tools for scientific communication; a learning community using the PlanetMath encyclopedia as part of a remix-driven interactive textbook). We should do a careful evaluation of what has worked and what could be improved for next time. There is not room in the current paper to conduct this discussion, but framework proposed by Resnick *et al.* would be an excellent place to begin [13].

For all of its potential as a software showcase and its possible future role as a player in a larger landscape of related interlinked online communities, PlanetMath should, at least for the moment, be evaluated first and foremost as an encyclopedia. This too would be best as an ongoing task. For now,

[23] `http://maa.org`
[24] `http://mathoverflow.net`
[25] `http://trac.mathweb.org/planetary`
[26] `http://vanillaforums.org`

| | |
|---|---|
| **Coverage** | The median entry would be an advanced undergraduate or beginning graduate topic. PlanetMath is generally considered to have more in-depth treatment of technical issues, e.g. of proofs, than Wikipedia. |
| **References** | Present in many articles, although there is not yet a unified database of references or style of presenting them (this is planned). |
| **History** | 315 items, mostly 20th Century or later.[27] |
| **Audience** | Consistent with the coverage, there have been 4127 posts in the "Graduate/Advanced" forum, 4261 posts in the "University/Tertiary" forum, and 1199 posts in the "High School/Secondary" forum. |
| **Clarity** | There is no hard and fast rule. Some articles are minimalistic, but precise (e.g. from strong contributors who have have English as a second language). Other articles may be verbose and vague. In any case, debates over clarity of presentation are intense, and a high standard is generally maintained (see Section 4). |
| **Pictures** | There are over 600 images, but this is only about 7% of all entries. A unified database/gallery of pictures might encourage more submissions. |
| **Accuracy** | At the time of this writing there are 48 outstanding corrections[28]; more than 14080 corrections have been filed since the site began, though 2337 are classified as "addenda", meaning that no mistake is implied, and 9182 are classified as "meta/minor", meaning that in the entire history of PlanetMath some 2561 real errors have been found through the peer review process (and all but a few fixed!). Note that these numbers do not take into account direct changes by authors (and would tend to under-represent error fixing in world-editable articles). |
| **Unusual** | PlanetMath provides "math for the people, by the people". |
| **Weight** | PlanetMath can be used from any browser, and comfortably edited from a lightweight laptop or netbook, weighing about 1kg. |

Table 1: Succinct review of the PlanetMath Encyclopedia

a quick summary following the outline used by Emma Previato in her review [11] of the *CRC Concise* gives us a look at how PlanetMath measures up (Table 1).

Because the technology that supports the site is special-purpose, we have been able to hone in on what works best for commons-based peer production in mathematics. Features like the autolinker facilitate integration of content, and the corrections system helps avoid messy battles. There is much more work to be done, but at the close of its first decade of life, PlanetMath may be poised to become a encyclopedia in the literal classical sense of a "complete instruction".

# The Planetary System: Web 3.0 & Active Documents for STEM

Michael Kohlhase[a], Joseph Corneli[b], Catalin David[a], Deyan Ginev[a], Constantin Jucovschi[a], Andrea Kohlhase[a], Christoph Lange[a], Bogdan Matican[a], Stefan Mirea[a], Vyacheslav Zholudev[a]

[a] *Computer Science, Jacobs University Bremen, Germany*
[b] *Knowledge Media Institute, The Open University, UK*

**Abstract**

In this paper we present the Active Documents Paradigm (semantically annotated documents associated with a content commons that holds the corresponding background ontologies) and the Planetary system (as an active document player). We show that the current Planetary system gives a solid foundation and can be extended modularly to address most of the criteria of the Executable Papers Challenge.

*Keywords:* active documents, executable paper challenge, content commons, semantic annotation, ontologies

## 1. Introduction

The Executable Papers Challenge (EPChallenge) calls for a framework that allows papers to be *executable*, give access to *provenance* and *copyright/licensing* information, and support various forms of *validation*. We contend that these challenges can be realized based on *semantically annotated documents* together with semantic background ontologies, which we call the **content commons**. This information can then be used by user-visible, interactive services like program execution, computation, visualization, navigation, information aggregation and information retrieval. Finally a document player application can embed these services to make documents executable. We call this framework the **Active Documents Paradigm** (ADP), since documents can also actively adapt to user preferences and environment rather than only executing services upon user request. In this paper, we present the ADP with a focus on the Planetary system as a document player on three distinct annotation levels, "presentation structure", "semantic", and "formal".

The Planetary system (see [1] for an introduction) is a Web 3.0 system[1] for semantically annotated document collections in Science, Technology, Engineering and Mathematics (STEM). In our approach, *documents published in the* Planetary *system become flexible, adaptive interfaces to a content commons* of domain objects, context, and their relations. The system achieves this by providing embedded user assistance through an extended set of user interactions with technical documents, based on an extensible set of client- and server-side services that draw on explicit (and thus machine-understandable) representations in the content commons.

## 2. The Planetary System: Current State

Development on the Planetary system began in summer 2010 based on an established set of knowledge management components; we have tested it on a variety of paradigmatic document collections, which we will describe

[1] We adopt the nomenclature where Web 3.0 stands for extension of the Social Web with Semantic Web/Linked Open Data technologies.

doi:10.1016/j.procs.2011.04.063

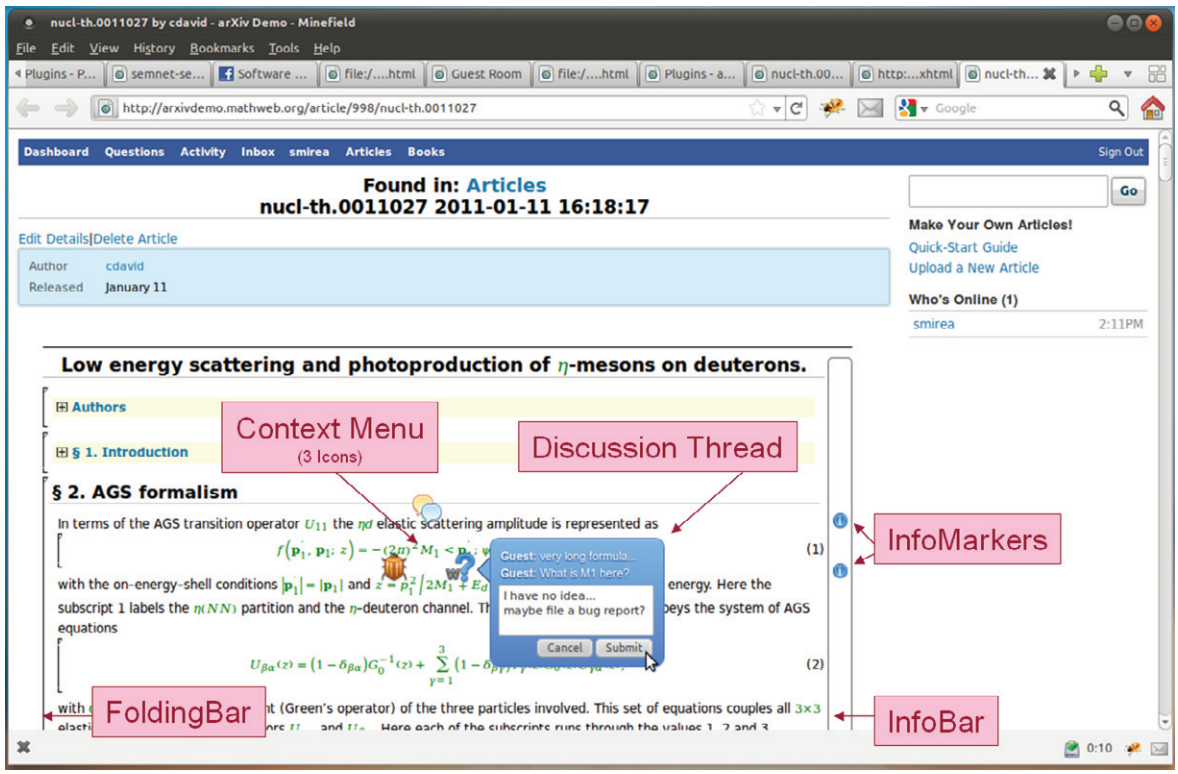

Figure 1: Interacting with an arXiv Article via `FoldingBar`, `InfoBar`, and Discussion Thread

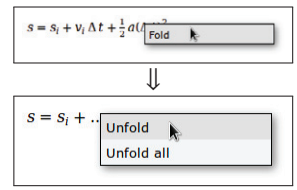


now. We group these by the level of semantic markup involved: generally, more semantic markup translates into more active documents, but requires a higher investment of the authors (but see Section 3.1). Note that PLANETARY gracefully adapts to the level of markup available: even though it was designed for the "semantic level" (see Section 2.2), it can also function well with a level of markup that can be extracted from pre-existing document formats, e.g. LaTeX (we call this the "presentation structure level"). The study of different levels of semantic saturation of individual documents is complemented by looking at libraries and collections of interlinked documents; Section 2.4 covers this aspect.

### *2.1. The Presentation Structure Level:* PLANETARY *arXiv and PlanetMath*

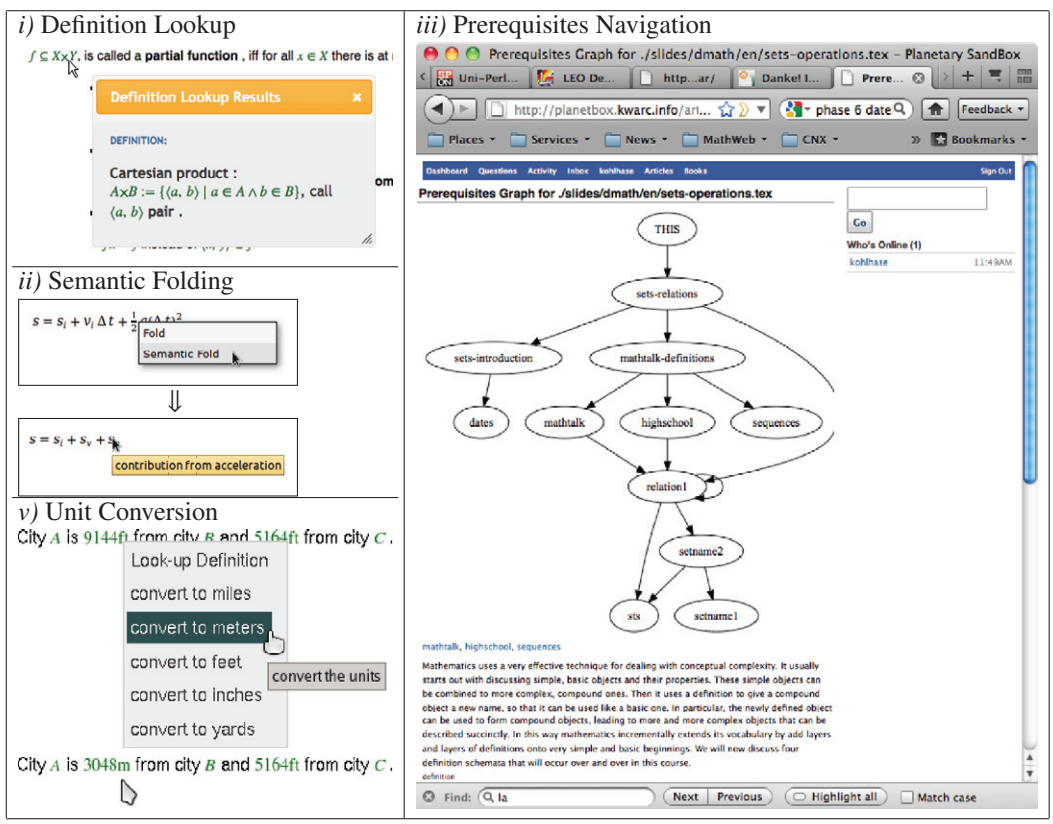
The importance of the presentation structure level is that PLANETARY can turn legacy documents into active documents by transforming them into XHTML+MathML+SVG-encoded documents with semantic annotations in RDFa. We have transformed over half a million articles from the Cornell ePrint arXiv to XHTML+MathML with LaTeXML [2], preserving properties like document and formula structures and embedded them into an instance of the PLANETARY system [3].

The document structure can then be exploited for a `FoldingBar` service (see on the left in Figure 1) and for localizing discussions about document content to document structures and subformulae – e.g. for questions/answers, or reviewers' comments. In the situation in Figure 1 we have clicked on formula (1), which pops up the `IconMenu` with three options: reporting errors in the content (bug icon), asking/answering a question (question mark icon), and accessing the discussion threads of this element (balloons icon). Here, a click on the question mark icon allowed us to pose a question and hope for an anser by other users in the forum. Figure 1 also shows the PLANETARY `InfoBar` with information markers on the right, which indicate the availability and state of the discussion threads pertaining to information objects in the line they are horizontally aligned with. Clicking them will highlight all items that have discussions. Localized discussions have proven a very valuable tool for community-based validation of papers, especially if they are coupled with a discussion subscription/trackback system for readers and personal notification system for authors.

The formula structure allows us to provide semantic services like subformula folding. The image on the right shows a formula from [3] where we right-clicked on the formula $s = s_i + v_i\Delta t + \frac{1}{2}a(\Delta t)^2$ for the law of uniformly accelerated motion to get the PLANETARY context menu. Folding a subformula (i.e., replacing it by an ellipsis marker yielding $s = s_i + \ldots$) yields the lower (simplified) formula, which in turn can be unfolded again whenever wanted.

### 2.2. The Semantic Level: Semiformal Digital Libraries

We can considerably improve the user experience by extending the depth of semantic annotations. For this we employ OMDoc [4] (Open Mathematical Documents), an XML-based content-oriented, semiformal representation format for scientific and technical documents. It builds on the OpenMath/MathML3 semantic representation format for mathematical formulae [5, 6]. OMDoc extends OpenMath with an infrastructure for context and domain models from Formal Methods, as well as a generic document infrastructure. At the semantic level PLANETARY is based on STEX documents [7], which can be transformed to OMDoc and via a user-adaptive and context-based presentation process further to XHTML+MathML+SVG+RDFa. The generated OMDoc documents are committed to an instance of the versioned XML database TNTBase [8] that indexes them by semantic functional criteria, and can then perform server-side semantic services via user-defined XQuery queries.



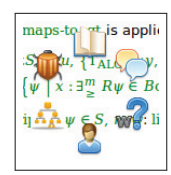


Figure 2: User Services at the Semantic Level

TNTBase thus becomes a source of the user-adaptive, custom-generated documents forming PLANETARY's content commons. Many semantic services can directly be derived from this setup. At the semantic level, the `IconMenu` we know from Figure 1 can be extended, depending on the services available for the semantic item in focus. The book icon triggers definition lookup (see item *i)* below) and the graph and portrait icons prerequisites navigation (see *iii)*). Figure 2 shows results of these and other services.

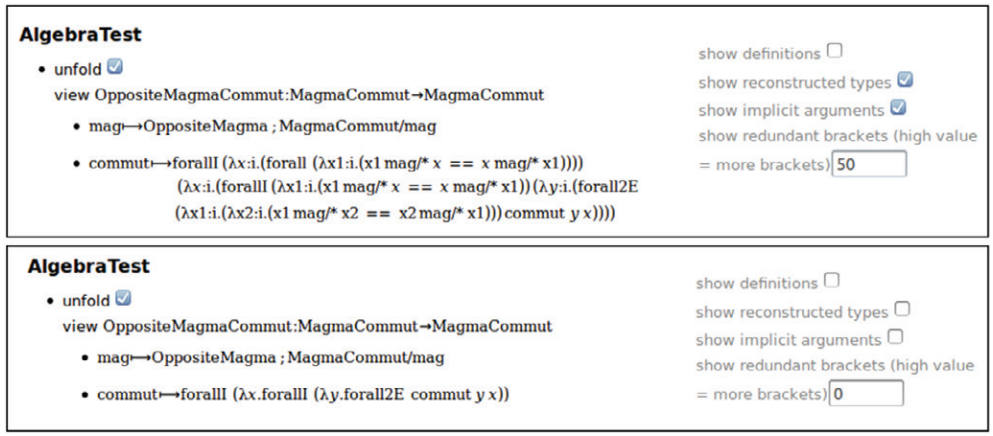

Figure 3: Formal Representations Adapted to Distinct User Settings (Customized via the `DocDash` Widget on the Right)

*i) Definition Lookup*: All technical terms and symbols in formulae presented in PLANETARY are linked to their semantic counterparts in the content commons, which in turn are linked to their definitions [9].

*ii) Semantic Folding*: If any explanations of the meanings of subformulae have been added as annotations, folding can use these instead of "...". In Figure 2/*ii)* the motion law above is semantically folded to $s_0 + s_v + s_a$ and the abbreviations $s_*$ are explained via flyover help.

*iii) Prerequisites Navigation*: As the content commons has an inherent notion of semantic dependency, we can use that to show prerequisites leading to a concept. Currently PLANETARY supports two ways of dealing with prerequisites: *i)* a *concept graph view*, where the required concepts can be navigated on demand by clicking on concept nodes, and *ii) guided tours*, where the necessary content is generated in a coherent narrative [10].

*iv) Executable Formulae*: As the formulae in the documents are generated from OpenMath objects, we can export them to a computer algebra system like Mathematica (or in our case the open-source system GAP [11], which has been made available as an OpenMath-based Web service [12]) for evaluation, graphing, or experimentation.

*v) Unit Conversion*: In scientific papers, formulae often contain expressions for measurable quantities; these can be automatically converted to other unit systems [9].

Note that the underlying OMDoc format and the services based on it address a peculiarity of documents in the STEM disciplines. Here, documents are *dynamic* in the sense that they declare new concepts, definitions, model assumptions, terminology, notations, etc., as they go along, or else they explicitly (or implicitly) import such items from other documents. As a consequence, all knowledge items in STEM documents have a non-trivial context of declarations. This must be managed explicitly in our representations of these documents, in the content commons, and within user interaction in order for semantic services to be effective. This effect is especially pronounced in mathematical sciences (including Computer Science, Physics, etc.), and somewhat less so in Chemistry and the Life Sciences, where a global context in the form of external terminology and notation databases often suffices.

### *2.3. The Formal Level: Specification and Verification*

Finally, we can use PLANETARY as a frontend system for completely formal content. OMDoc is also a foundation-agnostic integration format for mathematical knowledge that can express web ontologies [13, 14], program specifications and verifications [15], and even representations of logics in logical frameworks like LF [16]. In formal systems, documents are dominated by complex formulae, and users need support in navigating, abstracting, and evaluating them in order to cope with this complexity. Figure 3 shows how fully formalized formulae can be adapted to user preferences, about, e.g., the level of brackets and the availability of inferred arguments or definitions. Further semantic services at the fully formalized level include access to automated theorem provers via the HETS system [17] and argument reconstruction via the Twelf system [18].

It is important to note that programs (and program fragments) are also knowledge items at the fully formal level, as all their semantics can be recovered by parsing. Program fragments are not yet supported by PLANETARY (but see section 3.4).

### 2.4. The Network Layer: Library Integration of Document Metadata

We have concerned ourselves with individual active documents at various levels of semantic saturation so far. The PLANETARY system adds infrastructure for document collections and libraries as well (see Figure 4 and [19] for details). The library organizational level is realized as individual PLANETARY installations and provides the base URI of the system and its content. Examples include our PLANETARY-based scientific encyclopedia portal [20] or a course system. In these examples, the collection level corresponds to individual disciplinary encyclopedias such as PlanetMath [21] or individual courses in the course system. The contribution of the library and collection levels consists mostly in an inter-document, or network, layer of semantics via the aggregation of document metadata annotations. We represent metadata and cross-links between documents and their fragments as RDF graphs, reusing existing metadata vocabularies/ontologies[2] wherever appropriate. PLANETARY makes metadata and links editable to authors via LaTeX convenience macros, whereas some administrative metadata (e.g. the date of last modification) are recorded automatically. For services that interact with an active document, we employ *semantics-preserving transformations* that embed the metadata and links as user-invisible but machine-readable RDFa annotations.

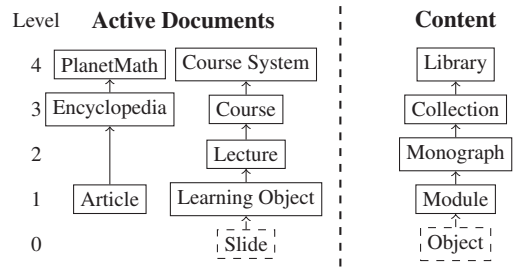

Figure 4: Levels of Organisation of Content

We keep metadata separate from the analysis of document semantics above to emphasize its independence of the document content, going one meta level up. This is also the justification behind its primary role as a connector (or least common denominator) between collections or entire libraries of documents, as opposed to the intra-document aspects outlined previously.[3] To enable this functionality, we add an RDF triple store as a system component and integrate it via its SPARQL endpoint API.

The utility of such annotations comes from (i) their reintegration into access methods or identifiers to collection and library subsets, and from (ii) the way PLANETARY makes the *vocabularies* of these annotations customizable and extensible within the system. Regarding (i), a generic mechanism of a "view" on a collection of documents can be instantiated to both simple and complex realizations, such as viewing the encyclopedia of PlanetMath alphabetically, by the Math Subject Classification (MSC [23]) categories of its articles or by posing the query "top rated new articles on Abelian groups, which were revised in the last three months (i.e. since I last read about such groups)". By making such views accessible by their own URLs, PLANETARY leverages the power of the resource locators in order to point to dynamic pages, which resolve an encoded metadata query. This new use of URLs generalizes the classic idea of what a resource is, in order to provide a more expressive way to communicate for users, for example in discussions about refactoring content, citing prior work, or pinpointing the next steps of a future effort. Regarding (ii), PLANETARY treats the annotation vocabularies used for metadata and links – their informal description, their formalization, and their documentation – exactly like any other of its STEM documents. In previous work (cf. [13, 24]), we have demonstrated that the OMDoc and STEX languages subsume common semantic web ontology languages, such as OWL, and go beyond them in their support for logical heterogeneity (cf. Section 2.3), integrated documentation up to literate programming (cf. Section 3.4), and modularity and reuse. By making the vocabularies editable inside PLANETARY, we enable the community to customize them. This is particularly powerful when a vocabulary immediately defines the functionality of a *service*, as is the case with our semantic discussion and refereeing facility explained in Section 3.3. Users (with sufficient permissions) can thus enhance the functionality of the service by introducing new vocabulary, they can refine the functionality by extending the formalization of existing vocabulary, and they can enable better user assistance by elaborating the documentation of those vocabulary terms that system functionality is based on. In that sense, *the ontology is the API* of the PLANETARY system.

We thus have the potential to envision metadata-enhanced social-semantic features such as subscribing to custom news feeds, social bookmarking, interoperability with external libraries and more.

[2] Here, we use the terms "vocabularies" and "ontologies" synonymously. Ontologies are the usual means of formalizing the semantics of vocabularies on the Semantic Web.

[3] Note that this separation is not total as there are interactions between the metadata level and the document semantics level. For instance, following a practice from the PlanetMath encyclopedia we use the NNexus tool [22] to semi-automatically discover concepts within documents (a document feature) and add links to their defining encyclopedia articles (a network feature).

### 2.5. The Active Documents Paradigm and the EPChallenge

We see the main impact of the Active Documents Paradigm and the Planetary system to the EPChallenge concentrated on the semantic level described in Section 2.2. At the presentation structure level the embeddable semantic services are largely limited by the semantic information that can be recovered from the LaTeX sources[4]. In the future some semantic annotations can be automatically discovered by heuristic or linguistic analysis methods [25], enabling services from the semantic level to be deployed on legacy documents. These analysis methods are subject to active research in our group, but beyond the scope of this paper.

Importantly, the Planetary system supports the incremental semantic upgrade of documents: any semantic annotation is directly made available to the semantic services, making documents more interactive, and thus contributes to the user experience of the enhanced active documents. This constitutes an opportunity for crowd-sourcing the semantic annotation of documents: Communities may propose annotations to documents which the document owner can then accept or reject. We can also think of alternative methods for quality control of semantic annotation, e.g. reputation/karma-based ones. A prerequisite for this will be tools that allow other users to express the semantic annotations, collect them, and incorporate them into the Planetary content modules as if they were author-supplied.

## 3. The Planetary EPChallenge Version

In this section we sketch how the Planetary system can be extended to answer most of the EPChallenge criteria before ICCS in June 2011. Details can be found on [26].

### 3.1. Semantic Editing Support

One of our priorities is to make the authoring process of semantic documents/discussions (to reach the semantic level) as easy as possible. We do that by providing a web-based authoring environment which lifts in-browser editing of sTeX documents to the level of popular LaTeX editors. Moreover, the environment is aware of sTeX semantics and can highlight fragments according to their functions (semantic syntax highlighting) as well as suggest autocompletions based on the context at request location. Crucially, the editor supports the creation of semantic links between documents, which is very tedious without this extension. For example, we implemented an instant search feature which helps the author in finding semantic concepts defined in other documents and subsequently reuse them without leaving the editing environment. Also, hovering over a concept shows its definition (if available), that is a definition lookup in the *source* document.

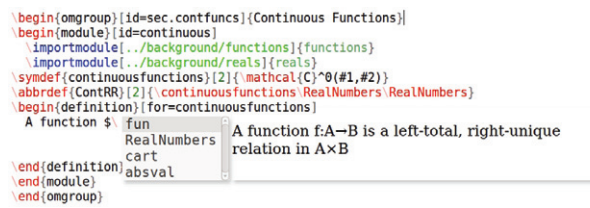

Figure 5: Autocompletion with Definition Suggestion

### 3.2. Integrated Semantic/Formula Search

Currently, the Planetary system only supports standard text-based search of the LaTeX/sTeX sources of articles and forum posts. We plan to integrate our currently independent semantic formula search engine MathWebSearch [27] for semantic content, using semantic copy-and-paste to alleviate/circumvent the remaining "math input problem". With such a formula search engine, a user can search mathematical content by its structure, e.g. the recollection that the energy of a signal $f(t)$ is given by the square of the signal integrated over time which can be expressed by a schema $\int_{\boxed{l}}^{\boxed{h}} \boxed{\mathrm{f}}(x)^2 dx$, where the boxed variables are search variables. This would find e.g. Parseval's Theorem $\frac{1}{T}\int_0^T s^2(t)dt = \sum_{k=-\infty}^{\infty} \|c_k\|^2$ (the search also took into account renaming the bound variable) which allows to compute the energy. Note that the definition lookup feature shown above comes in very handy here to look up the meaning of $c_k$: they are Fourier coefficients of $s$. The main problem to be solved here is to automatically infer the context of semantic elements in the documents. Formula search at the presentation structure level can be realized via heuristic transformations from presentation to content markup.

[4]Note that even though we have mainly studied documents that are automatically generated from LaTeX sources, initial experiments show that the Planetary system is equally applicable to other sources. In particular, the XML+MathML sources of Proceria Computer Science provided by Elsevier to the EPChallenge finalists could be integrated into the system after an afternoon's work.

### 3.3. Semantically Supported Discussions and Refereeing

We are semantically enhancing discussions with our previously developed argumentation ontology (which includes extensions to STEM-specific argumentative primitives) [28, 14]: Users can indicate categories for forum posts and fine-grained relations between forum posts and documents, or between posts and other posts. In particular, the argumentation ontology defines what types of *problems* apply to what types of STEM knowledge items (e.g. a declaration of a mathematical symbol can be ill-formed, but not invalid, as a proof could be), and what types of *solutions* apply to these problems (e.g. renaming a definition that a reader does not understand is less likely to solve the problem than providing an example for it).

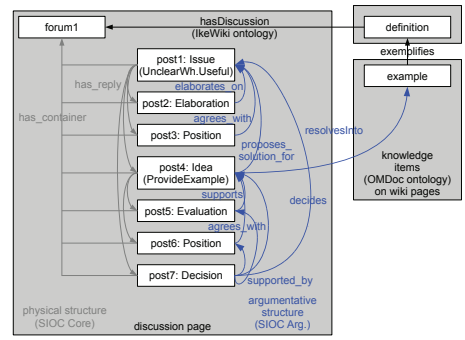

Figure 6: RDF Graph of a Discussion Thread about a Mathematical Definition (using our STEM-specific argumentation ontology)

The discussion facility is an application of our "ontology as API" approach introduced in Section 2.4, in that the discussion forum user interface uses such information from the ontology to guide users who want to write or reply to a post, and additionally reuses the documentation of the argumentation ontology as context-sensitive online help for the discussion forum user interface. As the argumentation ontology is editable inside PLANETARY, any community running a PLANETARY site can adapt it to their preferences, e.g. by defining new types of problems and solutions from their particular STEM subdomain, or refining the existing ones.

Adding versioned references [29] (facilitated by the TNTBase storage) allows incremental document/content commons development and commenting workflows to be managed in distributed teams. Building on the PLANETARY system's user management, we can extend this into a localized refereeing feature.

### 3.4. Program Fragments and Semantic Literate Programming

OMDoc and STEX have been used to deal with semiformal [15] and formal software engineering, but support for programming in the PLANETARY system is still lacking. The main problem to solve is that of modeling the scope of program fragments relative to background theory, e.g. in Computer Science papers. When that is solved, we will have a basis for "semantic literate programming", which can be supported by semantic services. To this end, we are currently working on integrating the notion of "biform theories" [30] into OMDoc for a more principled support of program fragments at the formal and semantic levels. Given this, we can make program fragments in a programming language $\mathcal{L}$ executable via an "universal OpenMath $\mathcal{L}$-Machine", a web service which accepts an $\mathcal{L}$-fragment $f$ and arguments $a_1, \ldots, a_n$ encoded as OpenMath objects (i.e. in the form in which they occur in the documents that appear in the content commons), executes $f(a_1, \ldots, a_n)$, and returns the result as an OpenMath object. With this web service, program fragments will be executable in analogy to formulae (see the services discussed in Section 2.2).

### 3.5. Management of Change

Keeping document collections consistent in the face of changes induced by development is a grand challenge in the STEM disciplines. Even though published documents are considered immutable, changes do occur especially in the development of STEM knowledge. It is a long-standing assumption that the semantic annotations in documents that drive the machine-supported interaction can support automated change impact analyses at the same time. Generally, any change in a semantic object (say a definition) induces an impact on all objects that depend on it. In [31] we have taken first steps of integrating a change impact analysis into the editing and management workflow of the PLANETARY system by establishing a flexible interface that allows to deal with impacts. One limitation of the current integration that we want to alleviate in the near future is that our integration currently assumes a single-user mode of operation. The main conceptual problem to be solved here is how to deal with propagating changes by "other authors". For that we plan to build in the notion of versioned links proposed in [29] in addition to our TNTBase versioned storage.

### 3.6. Integration of Scientific Data and Provenance

So far we have been mainly concerned with infrastructures for abstract and theoretical sciences. Papers in the natural sciences need an infrastructure for dealing with *experimental and measurement data*. We have already dealt with foundational aspects of experiments in [32]. For dealing with data aspects at the semantic level, we plan to build on the SACHS system [33, 34], our semantic user assistance system for spreadsheets, which understands spreadsheets as active documents with respect to a background ontology in the content commons. We plan to integrate the "semantic illustration" technology [35] originally developed for SACHS into PLANETARY, directly implementing its user assistance [36] into PLANETARY functionality, and generalizing the data handling and provenance functionality for scientific data. We conjecture that this will yield an integrative enabling technology for transparent, semantic embedding of data. When we additionally combine this with the executable programs feature from 3.4, we can document the computation steps that aggregated the data reported in papers from their experimental foundations and open them to experimentation for the user.

### 3.7. PLANETARY *Pit Stop*

Finally, users need to manage interface complexity (not all services are interesting to all users) and want to contribute their own services. We will build an "app store" for semantic services that hides the complexities of installation, shadowing, and removal.

## 4. Conclusion

We have presented the PLANETARY system as an example for the Active Document Paradigm (ADP) – semantically annotated documents connected to a content commons accessed through an adaptive document player – and as an answer to the challenge of creating "executable papers". We have shown the initial feasibility of the concept in a variety of publicly available case studies [3, 21, 37, 38][5]. Details on the system are available in the PLANETARY developer forum [39]. In particular, see the EPCsystem page [26] for more information and [40] for a sandbox installation of the system.

The PLANETARY system addresses all of the challenge categories. Concretely:

**Executability** is achieved by an extensible and configurable collection of semantic services that can be embedded into documents. In particular, code can be made executable via external computation machines, and computational experiments can be repeated and varied (via the same mechanism). Where the functionality of a service depends on ontologies, the user community can customize the service by customizing the ontology inside PLANETARY.

**Short and long-term compatibility** is guaranteed by usage of open standards in representation formats and protocols (XML, RDF/RDFa, OpenMath, MathML, XQuery, SPARQL, XHTML, SVG) supporting a web service framework, and hence operating-system-independent. Of course, PLANETARY can export monographs, collections and even entire libraries both as PDF (*inactive* documents) or in the EPUB eBook format.

**Validation** and in particular human refereeing and scientific validation can be facilitated via an in-text discussion feature. Moreover, documents can be automatically validated via semantic services, e.g. automated SI-dimensionality checking.

**Copyright/licensing** is represented by fine-grained RDFa-based metadata annotations in STEX and OMDoc, which are maintained over the presentation process. So they can be used for filtering or attribution either on the backend storage level (TNTBase, RDF triple store) or in the frontend PLANETARY system. Together with the user management and permission system, PLANETARY can be extended to enforce compliance. In fact, as documents are assembled for the user at view-time they can be adapted to the license status of the user (e.g. it is possible to make a document license conforming by leaving out examples that are not licensed to her specific institution).

**Systems** As the PLANETARY system is entirely based on web standards and communicates via RESTful interfaces, it is simple to wrap external systems into web services, if we can equip them with OMDoc, OpenMath, or RDF interfaces. In fact, that is exactly what runs the unit conversion service in Section 2.2/*v)*.

[5] Note that all of these are research systems under constant development, so your mileage may vary.

**Size** Even though individual human-written documents are modest in size, journals and encyclopedias can get big – consider e.g. the Wikipedia or the arXiv. The PLANETARY system has been tested on the latter; the underlying data stores scale sufficiently for large document collections. Furthermore, the modular and semantic document formats accommodate the integration of external data stores via 'special' links, which the PLANETARY player can interpret on view, hence keeping the storage minimal and the experience optimal. To the best of our knowledge, the semantically transparent integration of data into a document player application is a new feature of the PLANETARY system.

**Provenance** comes in various aspects. Data provenance can be specified by the techniques for semantic integration of data fields. For instance we can specify units (as OpenMath objects) and computations to obtain the displayed data from raw data, etc. As all of these are content representations in the documents or the content commons, they can be handled with semantic services. The system state provenance (i.e., what actions of the user led to the current state of interaction in the PLANETARY system), can be handled by recording system data ("who did what when") in the metadata store of PLANETARY. This can be opened to querying the system ontologies we have developed for semantically transparent system self-documentation (see Section 2.4).

An encouraging aspect of this work is that document authors only need expertise in their own domain. In particular, no system-level programming is necessary for authors: the semantic representation formats involved act as a high-level conceptual interface between content authors and system/service/interface developers. We are convinced that without such a separation of concerns, "the next generation of publishing" will not scale enough to become practical.

# Live Annotation and Content Discovery in Personal Learning Environments

Joseph Corneli and Alexander Mikroyannidis

Knowledge Media Institute, The Open University
Milton Keynes MK7 6AA, United Kingdom
{J.A.Corneli, A.Mikroyannidis}@open.ac.uk

**Abstract.** Personal Learning Environments (PLEs) are gradually gaining ground over traditional Learning Management Systems (LMS) by facilitating the lone or collaborative study of user-chosen blends of content and courses from heterogeneous sources, including Open Educational Resources (OER). Our work is focused on the social aspect of PLEs, and particularly on live interactions between learners, real-time annotation of OER and content discovery. This paper describes Gravpad, a service for sharing live annotations, and showcases how it can contribute to social learning within a PLE.

**Keywords:** personal learning environment, open educational resource, live annotation, content discovery

## 1 Introduction

Personal Learning Environments (PLEs) have recently emerged as an answer to the growing need for ubiquitous and flexible learning environments. PLEs follow a learner-centric approach, allowing the use of lightweight services and tools that can be accessed and customised from a variety of devices, such as PCs, netbooks, smartphones, etc. Rather than integrating different services into a centralised system, PLEs provide the learner with a variety of services and hand over control to her to select and use these services the way she deems fit [1].

In the context of the European project ROLE (Responsive Open Learning Environments[1]) we are working towards the transformation of OpenLearn[2], which is currently a public, course-centered LMS, into a PLE. The goal is to enable learners to easily construct and maintain their own learning environment, consisting of mash-ups of their preferred learning tools, services and resources, including:

- an e-portfolio describing learner goals and achievements,
- tools for collaborative authoring,
- tools for real-time meetings, and
- portals/aggregators connecting each learner to other learners and to additional external resources.

1 http://www.role-project.eu
2 http://openlearn.open.ac.uk/

There are some thematic critical questions to ask at the outset. The answers will frame our approach in the following sections.

*Question 1: What makes a "personal learning environment" special?*

The idea is that extra value can be delivered to the student by observing the way they interact in the PLE, and adapting the system's behaviour based on these observations.

*Question 2: Where will the aggregated content in the PLE come from, and how can we be sure it is useful?*

To the greatest extent possible, the PLE should be truly personalized by its users: not only should they be empowered to share content and ideas, but also to change the defining features of the system itself.

*Question 3: What is different about providing a collection of community-curated content on the one hand, and simply advising learners to use the internet as a whole on the other?*

The difference lies in the social aspect of working on topics of common interest. Search engines exist to provide access to information, but typically they do much less in the other direction, i.e. when it comes to sharing information with the world. This gap is partially filled by blogs, mailing lists, and so forth. However, we believe we can do better, by creating a service that adapts not only to the preferences and behaviour of individuals, but also to the behaviour of groups who share common interests.

In this paper, we will expand on these ideas through the particular example of Gravpad, a modified version of Etherpad[3] that can be used to make and share annotations to web content in real time. We will discuss the ways in which Gravpad relates to the other PLE elements mentioned in the bullet points above. First, we will review the PLE idea by looking at a particular learning scenario.

## 2 Personal Learning Environments: The OpenLearn scenario

The following scenario showcases the use of widget mash-ups in the context of collaborative authoring between OpenLearn users. Let us consider Ann, a student at the Open University, who is taking a course on sustainable energy (T206 - Energy for a sustainable future[4]). One of her group assignments is on the 10:10 climate change campaign. In order to assist the class in this assignment, her tutor has setup a special page in OpenLearn, with introductory OER from Open University learning units, iTunesU albums, and YouTube videos[5].

5 http://labspace.open.ac.uk/course/view.php?id=5177

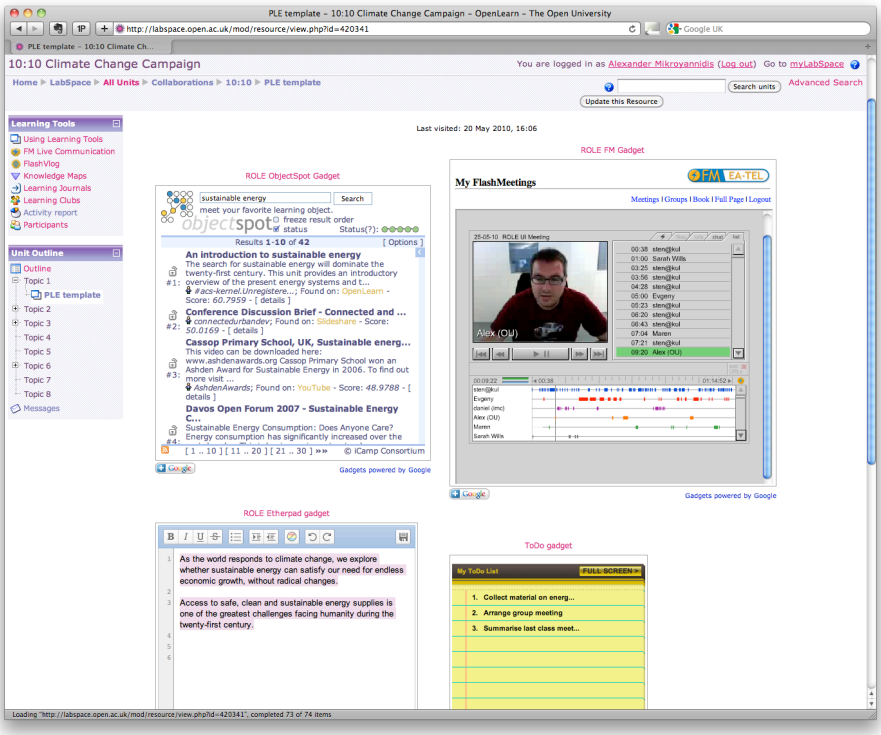

Figure 1. An OpenLearn PLE template for the climate change student[6]

Ann studies this material first, and then decides to explore some more. Her tutor has suggested a set of widgets within the OpenLearn PLE template shown in Figure 1. Ann starts off with the ObjectSpot search widget to discover more OER on sustainable energy, coming from OpenLearn courses, iTunesU, Wikipedia, SlideShare, and YouTube. She takes notes on the EtherPad widget, which she shares with her group members. She then has a videoconference with them, through the FlashMeeting widget, revising their joint notes on the EtherPad widget at the same time. Ann adds some figures about carbon emissions from the carbon emissions gadget into the group's EtherPad notes, and she and others in her group look for references to web pages about airlines that offer carbon offset services. Finally, Ann's group is ready to create their report for the assignment, by expanding and formatting their notes.

6 http://labspace.open.ac.uk/mod/resource/view.php?id=420341&direct=1

### 2.1 Swarms: A sense of co-presence

Suppose Stan is also on the same course, but in another group. Because the Etherpad widget is set up with Gravpad extensions, he is able to follow changes from other students in real time. For example, the URLs that Ann's group found about carbon offset programmes are drawn into a link aggregator shared by all course students. This is useful to Stan because his group has decided to focus on the impact of national polices around climate change, and he notices from Ann's notes in the link aggregator that carbon offset services tend to conform to the requirements of various national programmes. His group uses Gravpad to make further annotations attached to the pages Ann's group found, as shown in Figure 2.

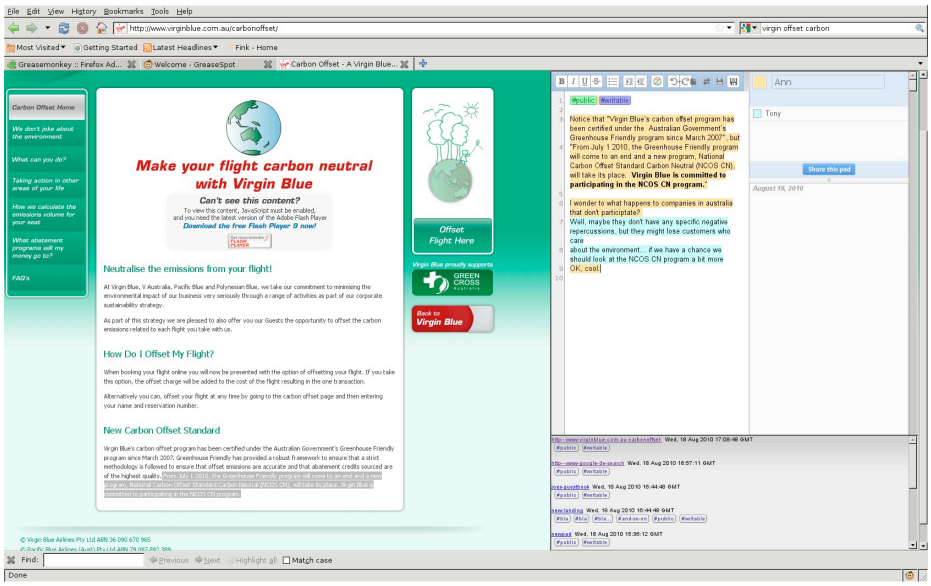

Figure 2. Group annotations and discussions via Gravpad

In the mean time, Ann's group has finished a first draft of their report. Before submitting, they check for activity in the course and find several key points they hadn't considered have been discussed in the notes attached to the pages that comprised their key references. They decide to make another round of revisions in light of the new things they've learned.

## 3 Implementing Gravpad

We saw in the previous example how social interactions can shape a learning landscape. Indeed, the central idea for Gravpad is precisely to "bend" a collection of existing content to one's purpose.

In a way, this idea is already present in the PLE concept. Annotations are just one example of a paradigm of social-semantic knowledge management. Gravpad operates as a recommender system applied in a real-time context; a variety of data streams in addition to web annotations could be used. For example, in [2], Wolpers et al. sketch out a broad scheme for making use of Contextualized Attention Metadata (CAM). This scheme resolves at a level of detail that includes things like the links followed in a given browsing session, or the programs used together in a given editing session. Gravpad should allow us to dive into interactions at a very fine-grained level, e.g. to make interventions on a word-by-word basis.

The current Gravpad implementation [3] has been built on top of the Greasemonkey[7] plugin for Firefox. This plugin allows the Javascript code of a modified Etherpad to be executed in the selected web page, offering a real-time, shared pad alongside the web page, as shown in Figure 2. The idea of using Etherpad to offer real-time writing advice is part of another contemporary research project (Dana Chandler, personal communication). Future implementation work around Gravpad will develop its usefulness in resource discovery, real-time context awareness, and social networking.

### 3.1 Free culture as motivator

Aaron Krowne writes in [4]:

> *"I contend that free culture is so compelling that users will be drawn to virtual places that allow them to work with it, use it, manipulate it, and bring it into the context of their lives and their interests."*

Krowne cites the work of Brusilovsky *et al*. on web annotation (cf. [5], [6]) as one example of a "free culture" trend.

Comparing Etherpad and the Web, we see the difference between a radically open/free production model (given the URL of a pad, anyone can contribute) and a more closed, ownership-based model (I control what happens on my domain, my blog, my course, etc.).

We also see how these two models fade into one another (e.g. Etherpad's "pro" setting allows the user to create a password-protected collection of pads, and blogs are typically open for comments). Even so, Etherpad seems paradigmatic for today's "open web". Gravpad mashes up this new radically open model and the more staid model of Web 1.0.

The resulting ability to make comments on anyone's web page without their explicit or implied permission, combined with the ability to filter out comments and pages based on various user-definable and extensible criteria, including content-based, time-based and social metadata, all serves to suggest that Gravpad may be "web annotation done right" – at least from the point of view of free culture. If user freedom is indeed a strong incentive for participation, will be what counts.

---

[7] https://addons.mozilla.org/en-US/firefox/addon/748/

### 3.2 Buy-in and scalability

Now that Etherpad is available as an easy-to-install open source tool, it can be deployed on any GNU/Linux-based server, and mixed with any collection of tools to gather and manage data about interactions.

Accordingly, Gravpad could be used "internet-wide" – or on a very small scale. New features in Etherpad and Gravpad allow for fine-grained management of access and event notifications. As mentioned above, Etherpad is only one of many potential sources of content that could be exploited by a Gravpad server in order to make high-quality recommendations.

Of course, syndicating operational transform data is more intensive than syndicating lightweight status changes. In the current demonstration version of Gravpad, recent changes are just published as JSON data. In principle, a distributed collection of Etherpad instances could be polled for changes in a similar manner, and their recent changes lists aggregated. The Salmon Protocol[8] provides a way for "annotations to swim upstream to original update sources", which could remove the need for active polling in favor of a push-based mechanism.

Future challenges in include federating Gravpad servers (perhaps taking the Wave federation protocol as a starting point[9]); becoming increasingly proficient at noticing implicit connections, in order to create explicit annotations; and developing additional tools to measure the "closeness" and mutual attraction of resources and activities, and the appropriateness of recommendations using these measures.

## 4 Related work

Google Wave is the most well known related example. We can learn several things from the course of development taken by Wave.

1. *Don't try to do everything on one centralized server*. As noted, Wave was designed with federation in mind, but Etherpad is perhaps already ahead of the game simply by being easy to install on your own server.

2. *Do one thing and do it well*. Etherpad seems to get perfect marks here. Wave may have suffered from being too complex for both users and developers.

3. *Be compatible with the way people already work*. For example, Jan Moringen and Joe Corneli have been working to integrate Emacs and Etherpad in a branch of the Rudel project[10]. At the opposite extreme, Wave wasn't directly connected to more popular Google tools like Gmail, which seems like a missed opportunity.

---

8 http://www.salmon-protocol.org

9 http://www.waveprotocol.org/

10 http://www.emacswiki.org/emacs/Rudel

At the same time, despite being discontinued as a stand-alone project, Wave's legacy may be with us for a long time, either in the form of Google API-based products (like social widgets), or the Novell's Wave-like and Wave Federation-compatible Pulse[11].

In any case, real-time collaboration is here to stay. People have used the idea of operational transform since 1989 [7] to synchronize content ranging from digital designs to raw data [8]. The literature on personalization and recommendations is too large to review here, but one can begin with a recent book [9]. Finally, new standard for syndicating semantic information about real-time interactions has been coming into its own recently in the form of "Activity Streams"[12].

Current Web 2.0 practices in user-generated annotations can also provide us with useful directions. A popular way for organizing content in Web 2.0, is tagging it with descriptive terms. This bottom-up collaborative process results in social classifications known as folksonomies [10]. An important aspect of a folksonomy is that it does not contain a hierarchy, or any directly specified parent-child or sibling relationship between its tags. Nevertheless, there exist relations that cluster tags referring to common resources. Compared to ontologies, folksonomies offer greater flexibility and adaptability in organizing information. A similar approach can be adopted in this project for organizing the annotations users produce in real time.

## 5 Conclusions and Future Work

We have seen that Gravpad gives people the opportunity to share context, whether temporal (co-editing a document in real time) or spatial (comments appear in-place, attached to the objects of interest). We also saw in an example how Gravpad can spread interactions out over time, bringing new resources to light and new creating opportunities for multimodal interaction in a shared PLE. Our future efforts will be directed towards integrating Etherpad with other social gadgets in the PLE, and on refining our recommendation algorithms accordingly. Finally, a key theme of this paper has been that interaction tools should be tailored to their users (and not the other way around), and we will endeavor to make Gravpad, like Etherpad, easy to customize and extend.

## ABSTRACT

GravPad is the next major step in the evolution of the EtherPad, a real-time collaborative editor that was first developed at AppJet, Inc. (`http://appjet.com/`) and recently open-sourced when AppJet was acquired by Google. EtherPad's developer community, headed up by Egil Möller and John McLear, has made a plugin engine and added standard wiki features to the editor (`http://github.com/ether/pad`). My GravPad demonstration will show a hacked EtherPad running in a "sidewiki" format – the basis of a platform for live web annotation and content discovery.

## Categories and Subject Descriptors

H.3.5 [**Information Storage and Retrieval**]: Online Information Services—*Data sharing, Web-based services*; H.3.1 [**Information Storage and Retrieval**]: Content Analysis and Indexing

## General Terms

Design

## Keywords

Wikis, Annotation, Content discovery

## 1. A NEW WAY TO COLLABORATE

In addition to facilitating live, *in situ*, interaction with web content (Fig. 1), GravPad users can receive real-time notifications about activity taking place anywhere on the web, filtered according to settings in user profiles (Fig. 2). Users will be able to follow people (like on Twitter, indeed, 'following' lists can be imported easily), pages (like using a Watch List on a wiki), or concepts (something new).

Combinations of these effects can be used to "bend" the web around one's interests. For example, GravPad together with `http://gutenberg.org` would create a massive world-wide book group, which a user can then narrow to focus on topics like "science" or "detective fiction". User profiles can also be linked together to facilitate swarming behavior, e.g. when working on a class project.

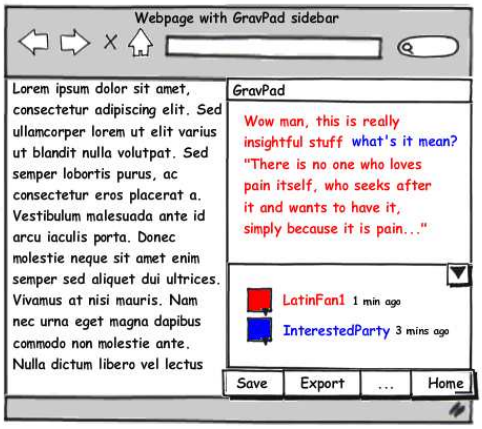

**Figure 1: Live interaction**

As it matures, GravPad will be great a place to experiment with the temporal and social dimensions of PageRank-like algorithms. In my presentation, I hope to attract interested parties to collaborate on future development.

Eventually, GravPad should have plugin, web portal, and drop-in Javascript interfaces, in order useful to many different people and organizations "right out of the box". Thanks to the idea of bending, web annotation will be positioned as a key productivity tool for the next decade.

## 2. THE DEMONSTRATION VERSION

I will begin with a brief tour of the new UI features that have been added to EtherPad since its open source release; features that transform it from being a real time collaborative editor, to being a real time wiki (i.e. links, tags, and a live recent changes page).

I will then show how this real-time wiki can be integrated seamlessly into the browsing experience as a plug-in in Firefox. This plugin will allow the user to open a sidebar containing a "live wiki page" hosting a discussion about the current URL, and a scrolling "live recent changes" frame showing any activities taking place on the Web that the user has

Permission to make digital or hard copies of all or part of this work for personal or classroom use is granted without fee provided that copies are not made or distributed for profit or commercial advantage and that copies bear this notice and the full citation on the first page. To copy otherwise, to republish, to post on servers or to redistribute to lists, requires prior specific permission and/or a fee.

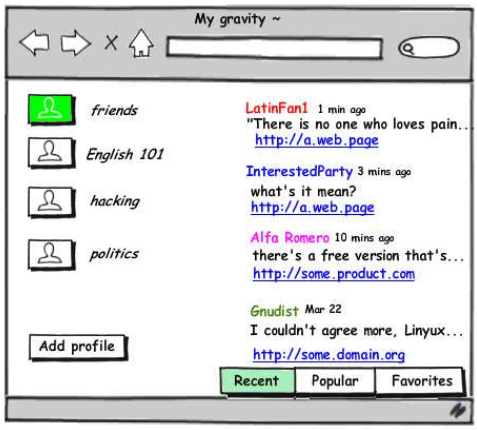

**Figure 2: Receiving notifications**

asked to be notified about.

The plugin's configuration will allow the user to create several profiles, each of which can specify pages, people, and concepts to subscribe to. This version of GravPad matches concepts using the "concept forest" algorithm introduced in [2].

## 3. CONCLUSION

Although "really real-time" document-based collaboration has been possible for some time using programs like Gobby [1], spreading such interactions across the web seems to be something new. Scaling up presents a variety challenges, but already we see in this demo how GravPad's two key features – live interaction and intelligent content discovery – make it a truly social tool, and an important step towards the "read-write web".

## 4. ACKNOWLEDGMENTS

The research work described in this paper is partially funded through the ROLE Integrated Project, part of the Seventh Framework Programme for Research and Technological Development (FP7) of the European Union in Information and Communication Technologies. The figures were made with Balsamiq Mockups.

I would like to thank Craig Ugoretz for preliminary discussions about the GravPad backend. Many thanks also to the EtherPad team!

# eMath 3.0: Building Blocks for a Social and Semantic Web for Online Mathematics & eLearning

Catalin David[*], Deyan Ginev[*], Michael Kohlhase[*], Joseph Corneli[†]

October 27, 2010

**Abstract**

In this paper we present recent developments in content markup for mathematics, and a corresponding software stack that functions as an enabling technology for a social and semantic web for the STEM disciplines. We show the potential of this technology in two eMath 3.0 applications: PlanetMathRedux, a re-implementation of the mathematical encyclopedia PlanetMath.org, and PantaRheiRedux, a community reader for course materials. These applications indicate both present and potential uses for this software as a basis for eLearning applications in Science, Technology, Engineering and Mathematics through the addition of suitable pedagogies.

## 1 Introduction

The Internet has revolutionized our access to information: much of what we need to know is available online, and can be found via search engines. In the last decade, this trend has been accelerated by the advent of the social and semantic web.

The *social web* (also called Web 2.0) fills various online commons with user-generated content and peer-based interactions. The social web has greatly extended the material available on the Internet; for instance, Wikipedia has accumulated more than 16 million articles in almost all the world's languages over the last 10 years.

The *Semantic Web* (by convention, referred to with capital letters) adds formal descriptions to web resources, so that the information they contain becomes machine-understandable. Semantic information retrieval can be used to combine different information sources to obtain facts and functionalities that are entailed, but nowhere explicitly represented, in the original sources themselves.

[*]Computer Science, Jacobs University, Germany; `http://kwarc.info/people/`

[†]Knowledge Media Institute, The Open University, UK; `http://metameso.org/~joe`

intro.tex 300 2010-10-26 11:44:03Z jcorneli

The emerging combination of social and semantic web techniques has sometimes been called Web 3.0. Applications like semantic wikis (see e.g. [Lan+10] and earlier workshops) and DBPedia [Dbp] (a semantic query engine based on the content of Wikipedia) are showing the considerable promise of this mixed approach.

Perhaps surprisingly, the Semantic Web has not taken off for the Science, Technology, Engineering & Mathematics (STEM) disciplines, even though STEM documents are ostensibly more rigorous, have more overt formal structure, and should therefore be amenable to formal, programmatic, treatment via Semantic Web technologies. Three possible impediments seem to be likely explanations for the slow uptake:

1. Both the STEM and Semantic Web user communities are small compared to the social web as a whole.
2. There is significant inherent difficulty and complexity in STEM subject matter.
3. Special representation languages are used by both practitioners (e.g. mathematical and chemical formulae) and technologists (e.g. XML and ontologies).

We believe that the first two factors are in fact offset by the dedication of STEM practitioners, and we claim that the third one – which is the main problem – has been solved, for the mathematical sciences, by recent technological developments. We will survey these broadly in the next section, and describe in detail a specific set of related technologies developed at Jacobs University Bremen over the last decade in section 3. In section 4 we will then show how these building blocks can be assembled into an *eMath 3.0 system* system for developing and exploiting social and semantic mathematics on the Web. Section 5 concludes the paper, with an emphasis on planned future work.

# 2 Mathematics on the Web: MathML, OpenMath and RDFa

Technologies that provide support for Mathematics on the Web have been increasing in prevalence over the last decade, and have reached a state, where they will become universally usable out of the box. This has been especially driven forward by the continued development of MathML and OpenMath as representation formats for mathematical formulae, and by the integration of Semantic Web technologies into widely-accepted web standards.

## 2.1 Mathematical Formulae on the Web: State of the Art

For mathematical formulae, the relevant developments are:

**M1:** MathML3, the upcoming W3C recommendation [Aus+10] extends MathML with linebreaking support (important e.g. for mobile applications), markup for elementary mathematics (for high school eLearning), and completely reworks the integration of content markup into MathML. Furthermore, the improved integration of MathML into host languages and environments gives a more solid basis for Math-enabled web applications.

**M2:** MathML is in the main browsers: natively in Firefox, via the MathPlayer plugin in Internet Explorer, via CSS in Opera, and native MathML support in Webkit has recently been

state.tex 300 2010-10-26 11:44:03Z jcorneli

announced, so we can expect it in the Webkit-based browsers (Chrome, Safari and Konqueror) in the near future. Additionally, Math support for all browsers can be enabled via MathJax [Mat], a JavaScript-based solution for displaying MathML or LaTeX in the browser.

**M3:** MathML is part of the upcoming HTML5 standard [Hic10], which is expected to drive the application-centered Web in the future: MathML elements (both content and presentation) are placed in the DOM, in the MathML namespace.

**M4:** TEX/LATEX documents can be transformed to XHTML+MathML automatically by systems like Tralics [Tra] or LaTeXML [Mil]; see [Sta+09] for an overview.

**M5:** More and more word processors and office applications include support for mathematical formulae (most prominently MS Word since Office 2007), and allow an export to MathML [Car07].

**M6:** As a consequence, very large collections of mathematical documents have become available online marked up with standard web formatting, most prominently, Zentralblatt Math [Zbl] and a web-enabled version of the Cornell ePrint arXiv [Sta+10; Arx].

## 2.2 Semantic Web Technologies for Mathematical Documents

Semantic web technologies are able to describe relationships within and between mathematical documents above the formula level.

**S1:** Text fragments can be classified by their mathematical role and related to each other via RDF triples [MM04], which can be efficiently queried with RDF query systems like SPARQL [PS08].

**S2:** RDF triples can be embedded into XHTML documents via RDFa; the upcoming version RDFa 1.1 [Adi+10] extends this to arbitrary XML languages.

**S3:** HTML5 embeds similar functionality in web pages via "microformats"; see [Ten09] for an analysis.

# 3 The KWARC Technology Stack

In the last five years, the KWARC research group at Jacobs University has developed a stack of technologies for content-oriented representation of mathematics in Web contexts together with tools for processing and interacting with these representations in sophisticated ways (see Figure 1). They have arisen as generalizations of system components in the course of developing systems like the SWiM semantic Wiki for mathematics [Lan08], Panta Rhei, a semantic community reader [MK08], and the ActiveMath eLearning System [Mel+03a]. We will review them before we show in the next section how they can be re-combined in novel applications.

## 3.1 Representation: OMDoc & sTeX

OMDoc is an XML-based content-oriented representation format for scientific documents, which is now used in a large set of projects in Automated Theorem Proving [Mül06], eLearning [Mel+03b; KK08b; Koh07], eScience [HKS06], Document Retrieval [KŞ06], User Assistance [KK08a;

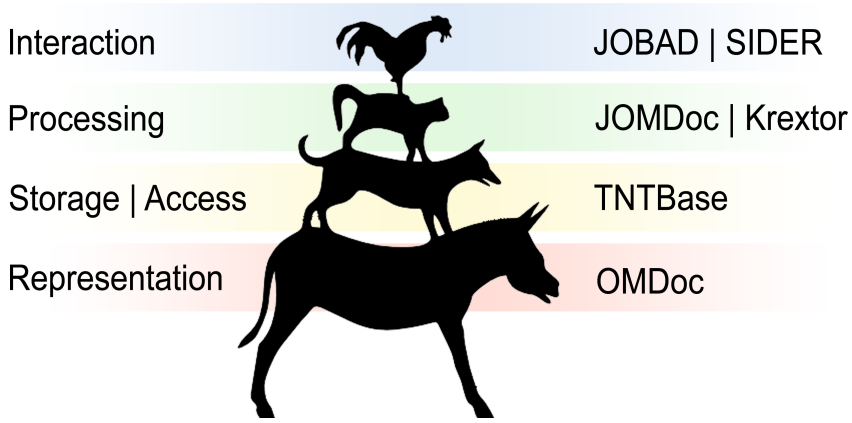

Figure 1: The KWARC Software Stack

KK09], and in Formal Digital Libraries [Url]. The OMDoc format builds on existing semantic representation formats for mathematical formulae (OpenMath [Bus+04] objects and Content MathML [Aus+03] representations), and extends them by an infrastructure for context and domain models from Formal Methods for important structural properties as well as for semi-formal content. Work on the OMDoc format shows that many added-value services in Knowledge Management do not need tedious formalization, but can be based at the structural/semantic level.

We have developed two approaches to ease the non-trivial task of authoring OMDoc documents. The first is an OMDoc-based semantic Wiki, which integrates server-based editing with user-adaptive and context-based presentation [LK08; Lan07]. The second approach we call an "invasive technology" [Koh05], since we build OMDoc-aware editing facilities into existing editing frame-works to make the most of existing functionalities and get around the learning curve involved with a new editor. We have evaluated this approach for MS PowerPoint [KK04; Koh05] and sTEX [Koh08; KKL10], a semantic variant of LaTeX; in both formats we can embed OMDoc markup as well as generate pure OMDoc as an export format.

## 3.2 Storage: TNTBase

Large scale collaborative authoring of mathematical documents requires versioned storage. On the language end, OMDoc supports this by making all identifiers URIs so that OMDoc documents can be distributed among authors and networks and reference each other. On the storage end, we use the TNTBase system [ZK09], a versioned XML-database with a client-server architecture. It integrates Berkeley DB XML with a Subversion server [Apa]. DB XML stores HEAD revisions of XML files; non-XML content like PDF, images or LaTeX source files, as well as differences between revisions, directory entry lists and other repository information are retained in a usual SVN back-end storage (Berkeley DB, in our case). Keeping XML documents in DB XML allows access to files via not only an SVN client, but also through the DB XML API, which supports efficient querying of XML content via XQuery, as well as (versioned) modification of the XML content via XQuery Update.

Versioning and distribution can also be realized with a plain SVN server, but for mathematics,

it is additionally important that the storage backend is aware of at least some aspects of the mathematical semantics. For example, in large-scale authoring processes, an important requirement is to guarantee consistency, i.e., it should be possible to reject commits of invalid documents. TNTBase can support format-specific validation of language-specific constraints and invariants that cannot be expressed in the XML schema languages.

For document management, TNTBase provides Virtual Documents. The author writes a Virtual Document skeleton document that embeds XQueries which are materialized by TNTBase when the content is served. This is particularly useful in eLearning applications, since Virtual Documents make it easy to generate aggregated- and user-adapted documents, as well as other kinds of document variants. TNTBase permits committing back changed Virtual Documents; the changes are distributed to the original files the Virtual Document was assembled from; see [ZK10] for details.

## 3.3 Processing: JOMDoc

JOMDoc [Jom] is a Java API for OMDoc documents, which facilitates parsing OMDoc XML documents into an internal Java data structure, allowing for convenient manipulation, and ultimately, serialization of this internal representation back to XML. JOMDoc has been integrated into TNTBase via the latter's plugin architecture for document format-specific customizations [ZKR10]. This makes made TNTBase OMDoc-aware so that data-intensive JOMDoc algorithms can be executed within the database, alleviating the need of sending the contents over the network for processing. Additionally, JOMDoc is used as a presentation framework for OMDoc. With its notation service [KMR08], it allows for context-sensitive rendering of XML documents containing mathematical formulae in content markup (Content MathML or OpenMath) into Presentation MathML. Optionally this can be presented as parallel markup, i.e., interlinked with the original content markup. Transformation of OMDoc documents to XHTML is supported by bundled XSLT stylesheets. In particular, this presentation service can be used to serve OMDoc documents in a human-readable presentation.

## 3.4 Interaction: JOBAD

Our JOBAD architecture embeds interactive mathematical services into XHTML+MathML documents. JOBAD is a modular JavaScript framework for interactive services such as term folding or definition lookup.

Our vision of a document is that it should be something the user can adapt according to his or her preferences and interests while reading it. This goes beyond customizing the display of the rendered document in the browser, to include, for example, changing notations (which requires re-rendering at least portions of the document), or retrieving additional information from services on the web to enhance the document with annotations. Consider a student reading lecture notes: whenever an unfamiliar mathematical symbol occurs in some formula, JOBAD enables the look up its definition without opening another document, but adds an explanation right into the current reading context. Converting between physical units (e.g. imperial and SI) can also be effected automatically, in-place and on the fly.

planetary.tex 301 2010-10-27 06:04:43Z kohlhase

# 4 The Planetary System: Assembling Applications

In August 2010, the authors started using the building blocks described in the last section to build a new front-end system for eMath 3.0 applications: the Planetary System. The starting point of this development project was our aim to make PlanetMath.org [Plab], one of the original eMath2.0 systems, more semantic, by integrating it with the KWARC technologies described in the last section.

PlanetMath.org is a relatively well-known online community devoted to mathematics. At present, its central feature is a mathematics encyclopedia with around 9K entries, which has been built and peer reviewed through effort of several hundred of volunteers since the site went online in 2001. PlanetMath also includes several general-purpose discussion forums which have received around 15K posts to date. Its most popular forums, containing about half of these posts, are devoted to Q&A about mathematics at the university, post-graduate, and research levels. Notably, each encyclopedia article also has its own attached discussion forum.

While the PlanetMath concept, community and vision remain alive and active, the Noösphere web application that underlies the site is showing its age. In particular, PlanetMath does not currently make significant use of any of the state of the art technologies described in section 2, other than using LaTeXas an input syntax.

To bring PlanetMath up to date, and simultaneously make its software easier to extend in the future, we decided to recreate the relevant functionality of Noösphere by integrating contemporary mathematical communication features into the existing open source web platform, Vanilla Forums. Vanilla offers a general-purpose online infrastructure, including user management and discussion forums, together with a plugin system that makes it relatively easy to adapt different components to a given special-purpose use.

Soon after we began to carry out this plan, we realized that Vanilla's plugin architecture would allow us to build a system that could be configured into multiple different eMath3.0 applications. This gave rise of the concept of the Planetary System. We are currently exploring its possibilities in two main applications: PlanetMathRedux [Plaa] (a new PlanetMath.org based on the Planetary System), and PantaRheiRedux [Pan].

## 4.1 The Software Base: Vanilla Forums

Vanilla Forums is an open-source, standards-compliant discussion forum platform with a very large user base (around 390K communities). Using this "off the shelf" forum software gave us a lot "for free", including user and permission management, and an extensive set of existing plugins to enhance the content and display. Most importantly, Vanilla's plugin architecture nicely complements the software stack that we already have which can be integrated into the system with plugins and applications, as described in the following subsections. The only significant problem we encountered with Vanilla was that while it is advertised to be XHTML-compatible, it seems to be only served with the `text/html` media type (as tag soup) in practice. Thus we had to correct numerous XHML validity errors when changing to the `application/xhtml+xml` media type, a prerequisite for embedding MathML into Vanilla.

## 4.2 Adding Math to Vanilla

Vanilla Forums does not provide authoring tools for mathematical formulae, hence we had to extend the forum functionality by adding a LaTeX-editor plug-in via the LaTeXML LaTeX-to-XHTML+MathML converter [Mil]. There were many alternatives to this choice (see [Sta+09]), but none of them scale to the full expressivity of LATEX, which is the input format used by PlanetMath.org. We were able to make use of our extensions to the batch-mode LaTeXML converter that turned it into a daemon web-service, to decreasing startup latency. This allows high-throughput conversion of arbitrary LaTeX fragments – ranging from simple expressions, to entire chapters or books.

We developed a Vanilla plugin that integrates the LaTeXML daemon with forum posts in the following manner: if a post is categorized as LaTeX then instead of letting Vanilla embed it into HTML directly, we first have it transformed by the resident LaTeXML daemon and integrate the XHTML+MathML result instead. Due to the swiftness of the conversion, it is possible to create "on-the-fly" editors like [Sta], in which the author can see the produced content as they type.

Using the LaTeX syntax significantly increases the expressivity of the authoring process when compared with Rich Text and Wiki syntax. LaTeX supports mathematical formulas, creating graphics and charts, easy fine-tuning of tables, complex page partitioning, custom commands, preambles, abbreviations, invasive preloading of semantics and more. Probably even more importantly, LaTeX continues to be deeply ingrained in contemporary mathematical publication and communication processes.

## 4.3 Encyclopedia Articles

The probably largest difference between standard Vanilla forums and PlanetMath.org is that the main content of PlanetMath is organized in and around "encyclopedia articles". Each of these is a versioned, LaTeX-encoded description of a particular mathematical object or topic, with an attached discussion, as we mentioned above. We added functionality for "encyclopedia articles" to Vanilla forums via a new "application" (Vanilla's term for a complex style of plugin that hooks into the same core, but adds new features, instead of merely changing old the way old features work). In contrast to unversioned forum posts, articles are stored in an associated Subversion repository, whose versioning functionalities are then exposed in the new interface. Vanilla's own database is used as a cache for efficient web publishing.

The default mode of navigating a content collection in Vanilla (based on listing articles by name) is unsuitable for the 9K articles in PlanetMath.org. Access via the Math Subject Classification (MSC [Msc]), as in the original version of PlanetMath.org, can be realized via the Vanilla Metadata scheme; we can even make these metadata properties versioned by encoding them into Subversion properties.

We have also added a new navigation method, called a "virtual bookshelf" which contains "books" created by users (here, authors, aggregators, or readers) according to their interest. The hierarchical document structure of a "book‘' is encoded by allowing inclusion primitives (a variant of "`\input`" from LaTeX) in articles, which then become sectioning nodes (e.g. chapters, sections), which can be mixed with transitional text. A narrative structure can be represented

simply as a "next" relation that links such articles. In a course setting, our Articles application can be used to highlight important books together with the forum interface (e.g. these may be portions of the course notes or other required readings).

With the JOBAD system we can already add a very nice feature to PlanetMathRedux: fine-grained forum posts. As JOBAD has access to the document object model (including that of the mathematical formulae in MathML), we can use it to attach forum posts to arbitrary document sub-structures, so that a user can e.g. ask a question about a particular definition, make a line-level proposal for an alternative proof, or offer a correction to a subformula. This fine-grained embedding of the forum into the documents allows Planetary System to be used as a "community reader", supporting discussion, document inspection, and refereeing.

The Articles application, together with the math editing plugin described above (and other some off-the-shelf Vanilla plugins) are enough to replicate most of the relevant parts of the Noösphere functionality, and they form the core of the PlanetMathRedux system. Note that PlanetMathRedux does not yet make any essential use of the semantics implicit in the articles.

## 4.4 Semantic Interaction

We consider mere "reading" of an article to be a deeply eMath2.0 activity and note that mathematics consumers will want to engage with the content of the article in more interactive ways, for more efficient and enjoyable learning experience. In mathematics, a dialogue with the expert is often a better way to settle an uncertain matter than reading a book, or searching through the library or the internet. Reading without thinking, computing and proving intermediate results is generally not the way to learn mathematics.

A prerequisite for the Planetary System to offer solid support for mathematical interaction is for it to have the content markup for articles available (and maybe eventually the corresponding content markup for forum posts as well). To support this, we have extended the articles application to handle sTeX. In this extension, we use TNTBase instead of Subversion and transform sTeX articles to OMDoc, which is then managed in TNTBase.

Our goal is to create "active documents" which adapt to the environment and can richly support user interaction. Some interactions only depend on information that is only related to the document at hand, e.g. the elision of formulae parts like brackets, types or inferable arguments. These can be implemented in the browser: JOMDoc exports the respective semantic information from the OMDoc representation into the XHTML+MathML documents as RDFa annotations [Adi+08], where they can be picked up via the document-embedded JOBAD services. For interactions that depend on larger amounts of data from outside the document itself, JOBAD implements call-backs to TNTBase. For instance, this is used for definition lookup, and for the generation of a concept graph of an exercise problem; see [Dav+10] for details on other services. In some cases, we need mixed computation models for semantic services, e.g. where some information is only present on the client (personal information which cannot be transferred to the server due to privacy concerns).

# 5 Conclusion & Future work

We have presented a set of content-based technologies (the KWARC stack) for building semantically and socially enabled math-aware online applications (eMath3.0 applications). We have shown how this can be done using our new Planetary System as an example. Originally planned as a re-implementation of the software underlying PlanetMath.org, it quickly grew more general and is now also used as the basis of PantaRheiRedux, a semantic eLearning platform in active use at Jacobs University.

We do not view the Planetary System (or the KWARC stack for that matter) as an eLearning system in its own right, but rather as an enabling technology for eLearning in the STEM disciplines. An eLearning platform additionally requires pedagogy. In PantaRheiRedux, the pedagogical aspects are minimal: the system gives access to the course materials, allows students to discuss them, and gives access to semantic services. It would be possible to add more pedagogy, e.g. formative assessments, learner modeling, adaptiveness and instant feedback based on the learner models.

We are planning additional applications of the KWARC stack and the Planetary System: in the arXMLiv project [Sta+10; Arx], we have transformed a large corpus of scientific papers to XHTML+MathML. We are currently working towards extracting a subset of the OMDoc format automatically from these, which would allow us to use the Planetary System as a lightweight community reading platform for the arXiv, where readers can discuss scientific questions, annotate semantic relations in the papers, and interact with the content of these papers more fully than in the current PDF-based system.

Finally, we are working on a version of the Planetary System for Formal Methods: we want to use the Planetary System as a front-end for a knowledge base of modular logic representations and logic transformations represented in an upcoming version of OMDoc; see [KMR] for details. The formal documents can support very powerful semantic services like borrowing automated theorem provers or the automated translation between formalizations in different logics. The formal setting provides a compelling angle on the useful range of this system, which we have seen includes support for both lightweight social to very intense semantic interaction.

# DOUBLE BUBBLES IN GAUSS SPACE AND SPHERES

J. CORNELI, I. CORWIN, S. HURDER, V. SESUM, Y. XU, E. ADAMS, D. DAVIS, M. LEE, R. VISOCCHI, N. HOFFMAN

Communicated by Robert M. Hardt

ABSTRACT. We prove that a standard Y is an area-minimizing partition of Gauss space into three given volumes, provided that the standard double bubble is an area-minimizing partition of high-dimensional spheres. We prove that the standard double bubble is the area-minimizing partition of spheres of any dimension where the volumes differ by at most 4%.

## 1. INTRODUCTION

In 2002, Hutchings, Morgan, Ritoré, and Ros ([HMRR], or see [Mo1]) proved the Double Bubble Conjecture, which says that the area-minimizing way to enclose and separate two given volumes in $R^3$ is a standard double bubble, defined as three spherical caps meeting in threes at 120 degrees. There have been partial extensions to $R^n$, the sphere $S^3$, and hyperbolic space $H^3$ ([Rei],[CF], [CH]). We provide extensions to $S^n$ and Gauss space $G^m$ for the case where each volume is approximately 1/3 of the total volume of the space.

1.1. **Single and Double Bubbles in Gauss Space.** Gauss space $G^m$, of much interest to probabilists (see e.g. [McK] and [Str]), is $R^m$ endowed with density

$$(2\pi)^{-m/2}e^{-x^2/2},$$

with total volume 1. Given any three positive volumes $V_1 + V_2 + V_3 = 1$, there exists a standard Y, unique up to symmetries of $G^m$, consisting of three half-hyperplanes meeting at 120 degrees, that partitions $G^m$ into three regions of those prescribed volumes (Proposition 2.11). Note that the center $m-2$ dimensional meeting plane of a Y passes through the origin if and only if the three volumes are equal. Our main theorem proves that the standard Y is area minimizing for certain cases:

> **Theorem 2.14**: *The standard Y is an area-minimizing partition of $G^m$ for three given positive volumes $V_1 + V_2 + V_3 = 1$, under the hypothesis that the standard double bubble for the same volume fractions is area minimizing in $S^n$ for infinitely many $n$.*

Section 3 proves that the standard double bubble is area minimizing in $S^n$ for all $n$ for nearly equal volumes. Using Brakke's Surface Evolver, Section 2.3 provides corroborating computer evidence that a standard Y is area minimizing for volumes $(1/3, 1/3, 1/3)$ (as we prove) and for volumes $(1/3, 1/10, 17/30)$ (which is outside our region of proof). This evidence makes it likely that the standard Y is minimizing for all volumes (see Section 1.2 below). It is worthwhile to note that while Section 3 proves a *unique* area-minimizing partition for certain volumes in $S^n$, the uniqueness of the corresponding partition in $G^m$ is an open question.

**The Proof.** The main idea comes from Mehler's 1856 observation that Gauss space is weakly the limit of projections of suitably normalized high-dimensional spheres (Proposition 2.1) as used by Borell [Bo] and Sudakov-Tsirel'son [ST] to prove hyperplanes optimal single bubbles in $G^m$. The proof requires stronger convergence of perimeter for fixed volumes (Proposition 2.12), including a technical Lemma 2.13 on how to repair small volume discrepancies at low area cost.

1.2. **Double Bubbles in $S^n$.** We prove the Double Bubble Conjecture in the sphere $S^n$ for volume fractions near 1/3:

> **Theorem 3.7**: *For all $n$, the $n-$dimensional standard double bubble is the unique area-minimizing partition of $S^n$ into any three volume fractions within .04 of 1/3.*

This, in conjunction with Theorem 2.14, proves that the standard Y is an area minimizer in $G^m$ if all three volumes are within .04 of 1/3. Section 3.3 shows how to extend this result to other volumes where the Hutchings function is positive. To extend to regions where the Hutchings function is negative, a different method of proof would be necessary. Reichardt et al. [Rei] proved that in $R^n$ it suffices to show that one region is connected. Extending this to $S^n$ would be a big step towards proving our result for all volumes.

**The Proof.** By Hutchings [Hu] and Cotton and Freeman [CF], it suffices to show that the Hutchings function $F_{S^n}(V_1, V_2, V_3)$ (Definition 4) of the prescribed volumes is positive. We consider more tractable lower bounds $\tilde{F}$ on the Hutchings function (Definition 5). By a monotonicity result of Barthe, it suffices to prove $\tilde{F}$ positive on high-dimensional spheres (Lemma 3.6). At this moment, we reuse the fact that Gauss space $G^2$ is the limit of projections of high-dimensional spheres,

so it suffices to prove $\tilde{F}$ positive in $G^2$ (Lemma 3.2), which we prove analytically (Lemma 3.3).

1.3. **Acknowledgements.** The authors would like to thank our advisor Frank Morgan for his continual guidance and input on this paper. The authors who were members of the 2004 SMALL Geometry Group (Corwin, Hurder, Šešum, Xu) further thank Morgan for bringing them to the Institut de Mathématiques de Jussieu Summer School on Minimal Surfaces and Variational Problems in Paris. We also thank the staff and organizing committee of the Summer School, especially Pascal Romon.

Lectures by Antonio Ros at the Clay Mathematics Institute Summer School [Ros] provided the initial inspiration for the investigation presented in this paper, which was first pursued by Corneli and others in the 2003 SMALL Geometry Group. The computer experiments of Section 2.3 stemmed from conversations with and help from Ken Brakke in Paris.

We thank Pat McDonald for his helpful comments on a preliminary version of this paper, and David Freeman for his comments in preparing this for publication.

We thank the NSF for its grants to the SMALL undergraduate research program and to Morgan. We also thank Williams College for support.

## 2. The Double Bubble Conjecture in Gauss Space

Our main result, Theorem 2.14, proves that the standard Y is an area-minimizing partition of Gauss space $G^m$ into three prescribed volumes, as long as the standard double bubble is area minimizing in high-dimensional spheres for the same volume fractions (as shown for certain volume fractions in Section 3). Proposition 2.1 provides the main idea: that Gauss space is the limit of projections of high-dimensional spheres. Section 2.2 discusses the standard Y, and Proposition 2.12 proves the convergence of standard double bubbles to the standard Y.

2.1. **Area and Volume Convergence in Gauss Space.** Gauss space $G^m$ is $R^m$ endowed with Gaussian density $f(x) = (2\pi)^{-m/2}e^{-x^2/2}$. We recall that volume and area in $G^m$ and in manifolds with density in general, are given by integrating the density with respect to the Euclidean volume and area (Hausdorff measure). Propositions 2.1 and 2.2 show that this density can be obtained by projecting high-dimensional spheres $S^n(\sqrt{n})$ of radius $\sqrt{n}$ into $R^m$. Proposition 2.4 shows that the areas of the inverse projections in $S^n$ of a hypersurface in $G^m$ converge to the area of the hypersurface as $n$ approaches infinity.

The following proposition, often attributed to Poincaré, is due to Mehler (see Stroock [Str], Exercise 2.1.40, page 76 and footnote page 77).

**Proposition 2.1** (Mehler, 1856)**.** *Gaussian measure on $R^m$ is obtained as the limit as $n$ approaches infinity of (orthogonal) projections $P_n$ of uniform probability density on $S^n(\sqrt{n}) \subset R^{n+1}$ to $R^m$.*

PROOF. Observe that $G^m$ is the projection of $G^n$ onto its first $m$ coordinates. The coordinates $X_1, \ldots, X_n$ of $G^n$ are Gaussian random variables. By the Central Limit Theorem, the distance to the origin $\sqrt{X_1^2 + \cdots + X_n^2}$ converges to $\sqrt{n}$ as $n \to \infty$. By the spherical symmetry of $G^n$, the volume of $G^n$ concentrates uniformly on $S^{n-1}(\sqrt{n})$ for large $n$. Therefore, $G^m$ can be obtained as the limit as $n \to \infty$ of projections $P_n$ of the uniform probability density on $S^{n-1}(\sqrt{n})$ or $S^n(\sqrt{n})$ to $R^m$. □

Furthermore, the induced density converges pointwise, not just in measure, to the Gaussian density.

**Proposition 2.2.** *The projections $P_n$ of the uniform probability density on $S^n(\sqrt{n})$ to $R^m$ for fixed $m$ converge pointwise to Gaussian density on $R^m$.*

PROOF. For a fixed $m$, let $f_n(x)$ be the density function resulting from projecting the uniform probability measure on $S^n(\sqrt{n})$ to $R^m$. By symmetry, we may assume that $x$ lies on the nonnegative first coordinate axis. Let $\theta$ be the angle between $S^n(\sqrt{n})$ and $R^m$; then $\sin\theta = x/\sqrt{n}$. A volume element $dV$ of $S^n$ is projected to a weighted volume element $dV\cos\theta$ on $R^m$. Therefore, a volume element $dV$ on $R^m$ has weighted volume $dV/(\cos\theta)$. Observe that $P_n^{-1}(x)$ is the $(n-m)$-sphere with radius $(\cos\theta)\sqrt{n}$ and thus has area proportional to $(\cos\theta)^{n-m-1}$. Therefore,

$$f_n(x) = c_n(2\pi)^{-m/2}(\cos\theta)^{n-m-2}$$

where $c_n$ is some normalization constant. Since $\cos^2\theta = 1 - \sin^2\theta = 1 - x^2/n$,

$$f_n(x) = c_n(2\pi)^{-m/2}(1 - x^2/n)^{(n-m-2)/2}.$$

Since $(1 - x^2/n)^{(n-m-2)/2}$ converges to $e^{-x^2/2}$ as $n \to \infty$, $c_n \to 1$, because the $f_n(x)$ converge to $f(x)$, the Gaussian density, in measure by Proposition 2.1. □

**Lemma 2.3.** *Let $g_n(x) = (1+x/n)^n$ and $g(x) = e^x$. Then $g_1(x) \le g_2(x) \le \cdots \le g(x)$ for all $x \in R$.*

PROOF. Note that $g_1(x) = 1 + x \le e^x$ for all $x$ by comparison of the derivatives.

Let $g'$ denote the derivative of $g_n(x)$ in $n$; we wish to show that $g' \ge 0$ for all $x$. Differentiating,

$$g' = \exp\left(n\log\left(1+\frac{x}{n}\right)\right)\left(\log\left(1+\frac{x}{n}\right) - \frac{x}{n+x}\right).$$

Since $\exp(n\log(1+x/n)) > 0$, we need only show that $\log(1+x/n)-x/(n+x) \geq 0$.

When $x$ is nonnegative,

$$\log\left(1+\frac{x}{n}\right) = \log(x+n) - \log(n) = \int_n^{x+n} \frac{dt}{t} \geq \int_n^{x+n} \frac{dt}{x+n} = \frac{x}{x+n}$$

and therefore $\log(1+x/n) - x/(n+x) \geq 0$.

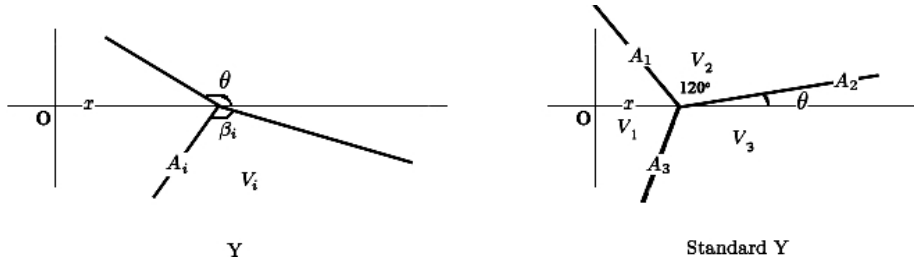
When $x$ is negative, $n+x < n$, so

$$-\log\left(1+\frac{x}{n}\right) = \log(n) - \log(x+n) = \int_{n+x}^{n} \frac{dt}{t} \leq \int_{n+x}^{n} \frac{dt}{x+n} = -\frac{x}{x+n}$$

and therefore $\log(1+x/n) - x/(n+x) \geq 0$.

Thus, the $g_n(x)$ are nondecreasing in $n$. □

**Proposition 2.4.** *The areas of the inverse projections to $S^n(\sqrt{n})$ of a measurable hypersurface $\Sigma \subset G^m$ converge to the area of $\Sigma$ as $n$ approaches infinity.*



PROOF. Define asymptotically equivalent density functions

$$F_n(x) = \frac{f_n(x)}{c_n} = (2\pi)^{-m/2}\left(1-\frac{x^2}{n}\right)^{n-m-2}$$

which differ from $f_n(x)$ by proportional constants $c_n$, which approach 1 as $n$ approaches $\infty$ (see proof of Proposition 2.2). By Proposition 2.2 and Lemma 2.3, $F_n(x)$ converges to $f(x)$ monotonically from below. By Lebesgue's Monotone Convergence Theorem, $\int_\Sigma F_n(x)$ converges to $\int_\Sigma f(x)$. Therefore, the areas of the inverse projections, $\int_\Sigma F_n(x)$, converge to the area of $\Sigma$, $\int_\Sigma f(x)$. □

2.2. **The Y and the Standard Y.** This section introduces the standard Y and its properties. Proposition 2.12 proves that the area of the standard double bubble on $S^n(\sqrt{n})$ converges to the area of the standard Y in $G^m$ of the same volume fractions as $n$ grows large.

**Definition 1.** A $Y$ in $G^m$ consists of three half-hyperplanes meeting along an $(m-2)$-dimensional plane. Let $\beta_i$ denote the angles between the hyperplanes. A *standard $Y$* is a Y with each $\beta_i = 2\pi/3$. Let $\theta$ denote the angle with the horizontal as in Figure 1. By $O(m)$ symmetry, we may assume that the $(m-2)$-dimensional plane lies normal to the $x$-$y$ plane and contains the nonnegative $x$-axis. The Y partitions $G^m$ into three volumes $V_1$, $V_2$, and $V_3$. The volumes partitioned by the standard Y satisfy $V_1 \geq V_2 \geq V_3$ as in Figure 1. Let $\mathcal{V}_i(x,\theta,\beta_1,\beta_2)$ and $\mathcal{A}_i(x,\theta,\beta_1,\beta_2)$ denote the volume and area, respectively, of the $i^{th}$ region as functions of $x$, $\theta$, $\beta_1$, and $\beta_2$.

Y Standard Y

FIGURE 1. We may assume that the Y is centered along the nonnegative $x$-axis. The standard Y partitions $G^m$ into volumes $V_1 \geq V_2 \geq V_3$.

**Lemma 2.5.** *In $G^m$, the values of $\mathcal{V}_i$ and $\mathcal{A}_i$ are independent of $m$ for $m \geq 2$.*

PROOF. This follows from the fact that Gauss space is a product measure and a Y has translational symmetry along an $(m-2)$-dimensional hyperplane. □

We state the following five minor lemmas without proof, the last two of which are used in Section 3.3. The proofs of these lemmas follow from simple geometric arguments.

**Lemma 2.6.** *In $G^m$, $\mathcal{V}_i(x, \theta, \beta_1, \beta_2)$ is continuous in $x$, $\theta$, $\beta_1$, and $\beta_2$, and for compact regions of $x$ and $\theta$, $\mathcal{V}_i$ is uniformly continuous in $\beta_1$ and $\beta_2$.*

**Lemma 2.7.** *In $G^m$, $\mathcal{A}_i(x, \theta, \beta_1, \beta_2)$ is continuous in $x$, $\theta$, $\beta_1$, and $\beta_2$, and for compact regions of $x$ and $\theta$, $\mathcal{A}_i$ is uniformly continuous in $\beta_1$ and $\beta_2$.*

Note that for a standard Y, we need only consider $0 \leq \theta \leq \pi/3$ due to $O(m)$ symmetry. Let $\mathcal{V}_i(x, \theta)$ denote $\mathcal{V}_i(x, \theta, 2\pi/3, 2\pi/3)$.

**Lemma 2.8.** *For a standard Y in $G^m$ with $x > 0$, $\mathcal{V}_1$ is strictly increasing in $x$ and strictly decreasing in $\theta$; $\mathcal{V}_3$ is strictly decreasing in $x$ and strictly decreasing in $\theta$.*

**Lemma 2.9.** *For standard Ys in $G^m$ with $V_1$ fixed, increasing $V_2$ increases the signed distance from the origin to the line between the regions of volume $V_2$ and $V_3$.*

**Lemma 2.10.** *For standard Ys in $G^m$ with $V_2 = V_3$, increasing $V_1$ increases the signed distance from the origin to the lines bounding the region of volume $V_1$.*

**Proposition 2.11.** *Given three volumes $V_1$, $V_2$ and $V_3$ such that $V_1+V_2+V_3 = 1$ and $V_1 \geq V_2 \geq V_3$, there exists a unique standard Y, up to $O(m)$ symmetry, which partitions $G^m$ into volumes $V_1$, $V_2$ and $V_3$.*

PROOF. By Lemma 2.5, we need consider only the case $m = 2$. We exclude the trivial case $V_1 = V_2 = V_3$. Since $\mathcal{V}_3(0, \pi/3) = 1/3$ and $\lim_{x\to\infty} \mathcal{V}_3(x, \pi/3) = 0$, by Lemma 2.6 there is a unique $x_0 > 0$ such that $\mathcal{V}_3(x_0, \pi/3) = V_3$. Similarly, there is a unique $x_1 > x_0$ such that $\mathcal{V}_3(x_1, 0) = V_3$.

For every $x_0 \leq x \leq x_1$, there is a unique $\theta(x)$ such that $\mathcal{V}_3(x, \theta(x)) = V_3$. Also, for $x < x_0$ or $x > x_1$, there exists no $\theta(x)$ for which $\mathcal{V}_3(x, \theta(x)) = V_3$. By Lemma 2.6 and the fact that $\theta(x)$ is continuous and strictly decreasing in $x$, $\mathcal{V}_1(x, \theta(x))$ is continuous and strictly increasing in $x$. Since $\mathcal{V}_1(x_0, \pi/3) \leq V_1 \leq \mathcal{V}_1(x_1, 0)$, there is a unique $x_0 \leq x \leq x_1$ such that $\mathcal{V}_1(x, \theta(x)) = V_1$ and, consequently, $\mathcal{V}_2(x, \theta(x)) = V_2$, proving the uniqueness of Y (Figure 2). □

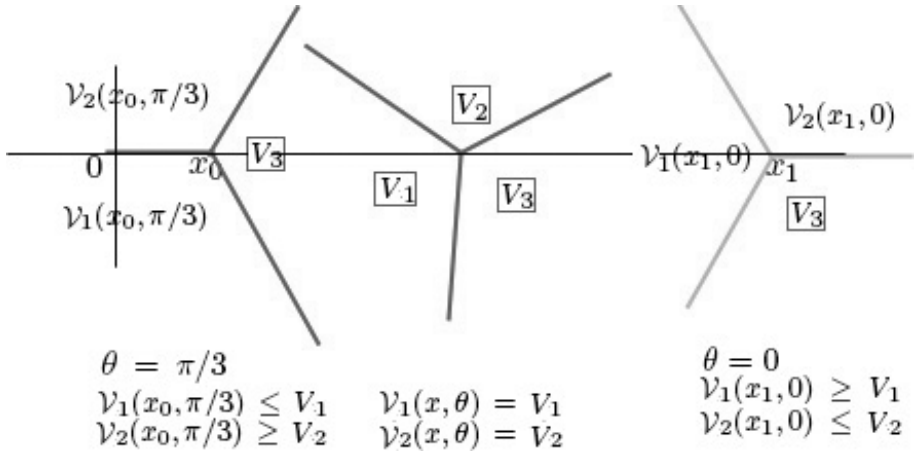


FIGURE 2. By the Intermediate Value Theorem, there exists a unique standard Y that partitions $G^2$ into given volumes.

**Definition 2.** A *standard double bubble* partitioning $S^n$ into three prescribed volumes consists of three $(n-1)$-dimensional spherical caps meeting along an $(n-2)$-sphere at 120 degrees. There exists a standard double bubble for any given set of prescribed volumes ([CF], Proposition 2.6.), unique up to isometries of $S^n$.

**Proposition 2.12.** *The area of the standard double bubble on $S^n(\sqrt{n})$ converges to the area of the standard Y in $G^m$ as $n$ approaches infinity for the same volume fractions.*

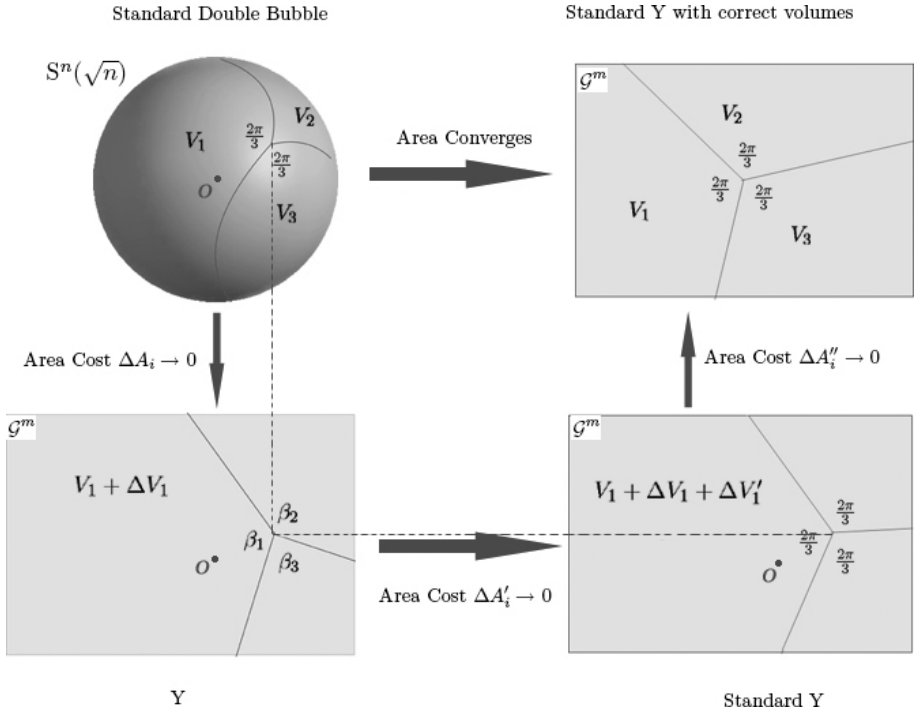

FIGURE 3. The Y projected from the standard double bubble in $S^n(\sqrt{n})$ can be transformed to the standard Y of the correct volume fractions with an area difference that approaches 0 as $n$ approaches $\infty$.

PROOF. Since the inverse image by the projection of a plane in $G^m$ is a sphere in $S^n$, the inverse image of a Y (three half-hyperplanes meeting along an $(m-2)$-plane) is three spherical caps meeting along an $(n-2)$-sphere at some angles. Given volumes $V_1$, $V_2$ and $V_3$, choose $\mathrm{Y}_n$ in $G^m$ (not necessarily with angles $2\pi/3$) with inverse image the standard double bubble (with angles $2\pi/3$) in $S^n$ with the given volumes.

The distance of the vertex of the $\mathrm{Y}_n$ from the origin is bounded above as $n \to \infty$, since too great a distance implies that $V_3$ is too small. As $n$ increases,

the radius of $S^n(\sqrt{n})$ increases, and the section of the sphere above the vertex of $\mathrm{Y}_n$ grows increasingly flat. Thus, the angles of the $\mathrm{Y}_n$ approach the angles of the preimage—namely, $2\pi/3$.

Let the volume and area differences between the standard double bubble in $S^n$ and the $\mathrm{Y}_n$ be denoted $\Delta V_n$ and $\Delta A_n$ as in Figure 3. By Propositions 2.1 and 2.4, the $\Delta V_n$ and $\Delta A_n$ approach 0 as $n \to \infty$. Rotate two rays of the $\mathrm{Y}_n$ so that the $\beta_i$ are all $2\pi/3$ (so that it is a standard Y, though not necessarily of prescribed volume), and denote the area and volume changes in the Y as $\Delta V_n'$ and $\Delta A_n'$. Since the changes in $\beta_i$ go to 0 as $n \to \infty$ and $x$ and $\theta$ are restricted to a compact region, Lemmas 2.6 and 2.7 imply that $\Delta V_n'$ and $\Delta A_n'$ both go to 0 as $n \to \infty$. By Proposition 2.11, this standard Y can then be rotated and translated so that it has the correct volumes $V_1$, $V_2$ and $V_3$. From Lemma 2.8, $V_1$ and $V_3$ are locally invertible in $x$ and $\theta$. Therefore, for the small volume change which goes to 0 as $n \to \infty$, Lemma 2.7 implies that there is a correspondingly small area change $\Delta A_n''$ which similarly goes to 0 as $n \to \infty$. Therefore, for prescribed volumes $V_1$, $V_2$ and $V_3$, the total area difference between the standard double bubble on $S^n$ and the standard Y is thus $\Delta A_n + \Delta A_n' + \Delta A_n''$ which goes to 0 as $n \to \infty$.

□

*Remark.* The proof above can be easily modified to show that the area of the single bubble of volume $V_1$ on $S^n(\sqrt{n})$ converges, as $n$ approaches infinity, to the area of the hyperplane partitioning $G^m$ into volumes $V_1$ and $1 - V_1$.

2.3. **An Area-Minimizing Partition of Gauss Space.** Theorem 2.14 proves that a standard Y is area minimizing in $G^m$ under the assumption that the standard double bubble is area minimizing in $S^n(\sqrt{n})$ for infinitely many $n$. The proof uses Lemma 2.13 to adjust volumes with controlled area cost. As in Proposition 2.2, let $f_n$ be the density of $R^m$ from the projection of $S^n(\sqrt{n})$:

$$f_n = c_n(2\pi)^{-m/2}(1 - x^2/n)^{(n-m-2)/2}$$

**Lemma 2.13** (Volume balancing at low area cost)**.** *Given a compact region $R \subset R^m$ and an $\epsilon > 0$, there exists $\delta > 0$ and $N$ such that for all $n > N$ and any $\Delta V < \delta$, a ball with $f_n$-weighted volume $\Delta V$ which is split by two hyperplanes has $f_n$-weighted total surface area (including the area of the hyperplanes inside the ball) $\Delta A < \epsilon$.*

Proof. Lemma 2.3 implies that $F_n = (2\pi)^{-m/2}(1 - x^2/n)^{(n-m-2)/2}$ converges monotonically from below to $(2\pi)^{-m/2}e^{-x^2/2}$ and assumes positive values for all

$x < \sqrt{n}$. By Proposition 2.1, the $c_n$ converge monotonically from above to 1. Hence, for $n \geq N$, $f_n$ is bounded below by $\min_R\{F_N\} > 0$ and bounded above by $\max_R(c_N(2\pi)^{-m/2}e^{-x^2/2}) \leq c_N(2\pi)^{-m/2}$. Therefore the surface area of the weighted ball goes to 0 with the volume. □

**Theorem 2.14** (An area-minimizing partition of Gauss space)**.** *The standard Y is an area-minimizing partition of $G^m$ for three given positive volumes $V_1 + V_2 + V_3 = 1$, under the hypothesis that the standard double bubble for the same volume fractions is area minimizing in $S^n$ for infinitely many $n$.*

*Remark.* Theorem 3.7 proves that the standard double bubble enclosing nearly equal volumes is area minimizing in $S^n(\sqrt{n})$ for all $n$. Corollary 3.8 combines that theorem with Theorem 2.14 above to prove that the standard Y is an area-minimizing partition of $G^m$ for nearly equal volumes.

Proof. Note that from scaling, an equivalent hypothesis to that of the theorem is that the standard double bubble for the same volume fractions is area minimizing in $S^n(\sqrt{n})$ for infinitely many $n$.

Let Y denote the standard Y with area $A$ and assume, to obtain a contradiction, that there exists a Y′ with area $A' = A - \alpha$ where $\alpha > 0$ (Figure 4).

By Proposition 2.12, for large $n$, the difference in area between the standard double bubble in $S^n(\sqrt{n})$ with the same volume fractions and the Y is less than $\alpha/2$.

Observe that there exists a compact region $R \subset R^m$ which contains distinct "Lebesgue" points of density 1 of each of the three regions. For the $i^{th}$ region, choose $\delta > 0$ as in Lemma 2.13 for $\epsilon = \alpha/12$ such that the balls are disjoint and the volume of $V_i$ in the ball exceeds half of the volume of the ball. The total surface area cost of constructing three such balls is less than $\alpha/4$.

By Propositions 2.1 and 2.4, for large $n$, the area of Y′ and the area of the preimage of Y′ on $S^n(\sqrt{n})$ differ by at most $\alpha/4$ while the volumes differ by at most $\Delta V'/2$. By Lemma 2.13, we can enclose in our balls at least $\Delta V'/2$ of each volume partition at area change of at most $\alpha/4$. Delete the volume from these balls and observe that every region now has less volume than it did in Y′. By splitting the balls with hyperplanes, we reassign the appropriate amount of volume to each region so that the total volume of each region equals the volume in each region of Y′.

We have just constructed a competitor on $S^n(\sqrt{n})$ to the standard double bubble. The total area difference between the competitor and the standard double

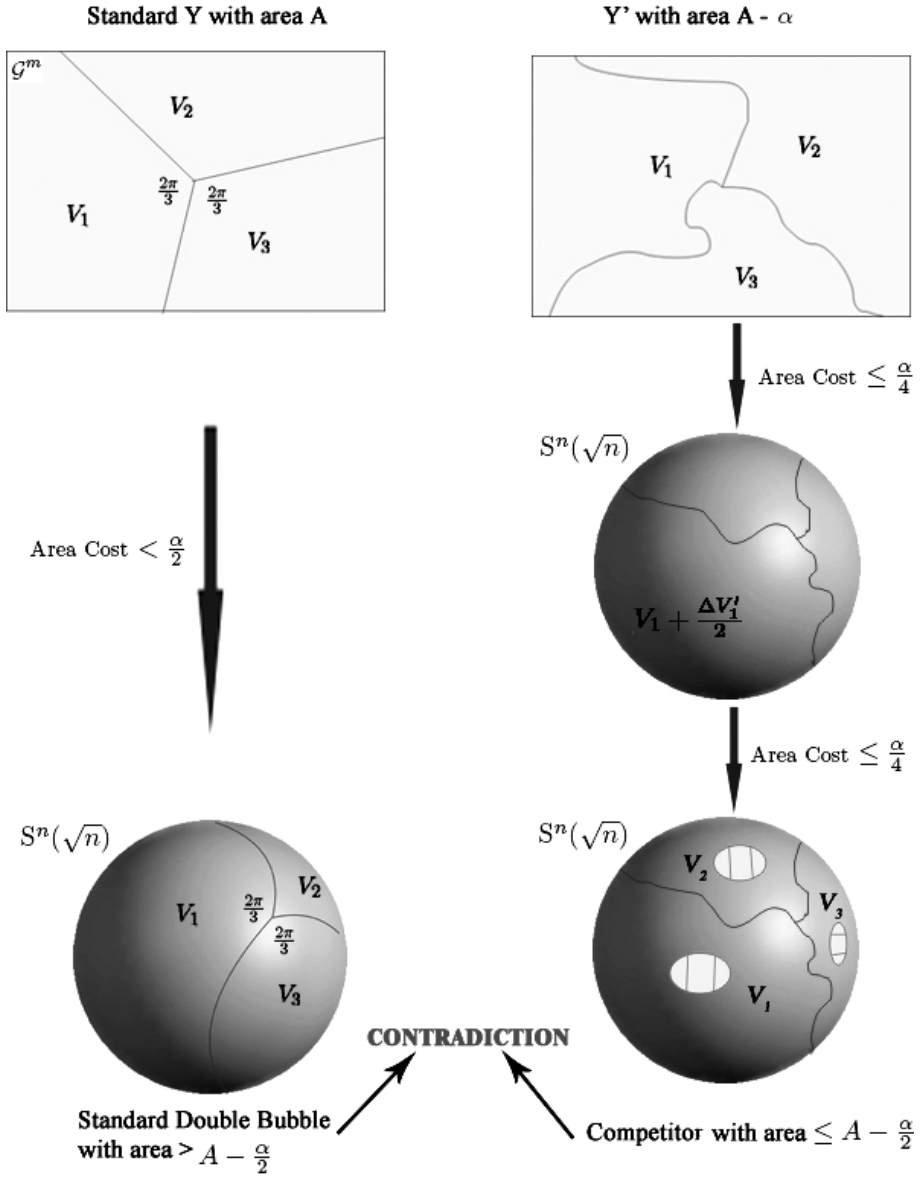

FIGURE 4. Assume there exists a Y′ better than our standard Y. This implies that the preimage of Y′ in $S^n(\sqrt{n})$ beats the standard double bubble, which is a contradiction.

bubble on $S^n(\sqrt{n})$ is less than $\alpha/2$ (area difference between the Y and the standard double bubble) plus $\alpha/4$ (difference between Y′ and preimage on $S^n(\sqrt{n})$) plus $\alpha/4$ (balls to balance volume), and hence less than $\alpha$. Y′ therefore partitions $S^n(\sqrt{n})$ into the three given volumes and uses less area than the standard double bubble, contradicting our hypothesis. □

*Remark.* Brakke's Surface Evolver [Br], available online at no cost, is a program expressly designed for the modeling of soap bubbles, foams, liquid solder, capillary shapes, and other liquid surfaces shaped by minimizing energy subject to various constraints. It inspired and helped us to simulate the perimeter-minimizing partition of three areas in $G^2$. It is a good way to see how the double bubble in Euclidean space turns into a standard Y in Gauss space.

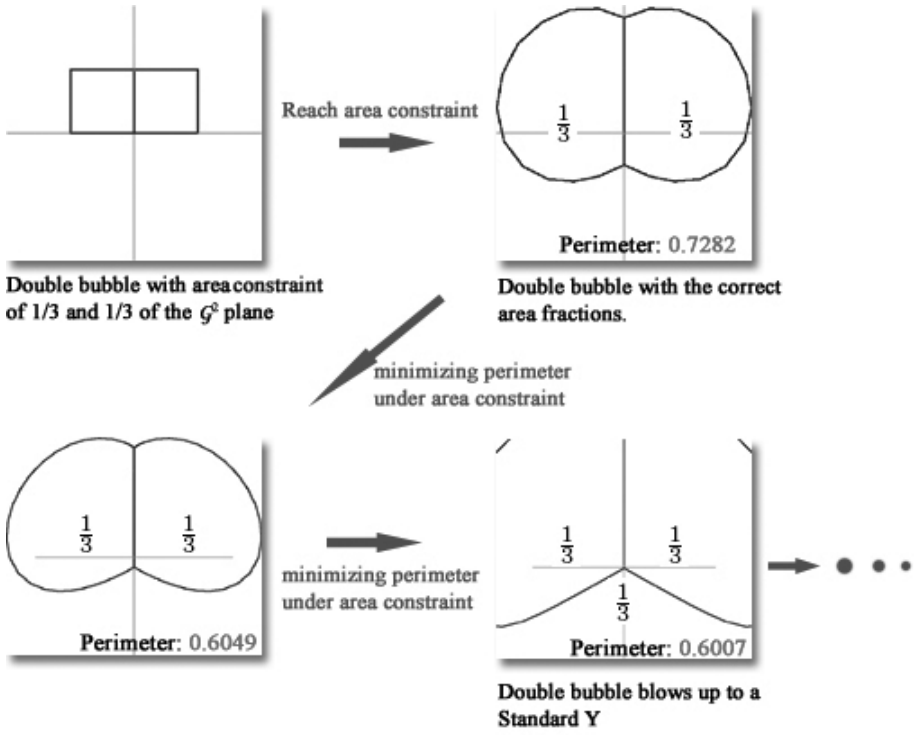

FIGURE 5. The evolution of an equal-area double bubble in $G^2$ of limiting perimeter 0.5984.

We first evolved the equal-area double bubble with area fractions $(1/3, 1/3, 1/3)$, as in Figure 5. Notice that the double bubble blows up and one vertex moves to the origin with three rays spaced approximately at angles of $2\pi/3$. The evolved shape has perimeter approaching $3/(2\sqrt{2\pi}) = 0.5984$, which is the perimeter of the standard Y at the origin.

We then evolved a double bubble with un-equal area fractions $(1/10, 1/3, 17/30)$. Notice that this bubble also blows up, forming a shifted standard Y (Figure 6).

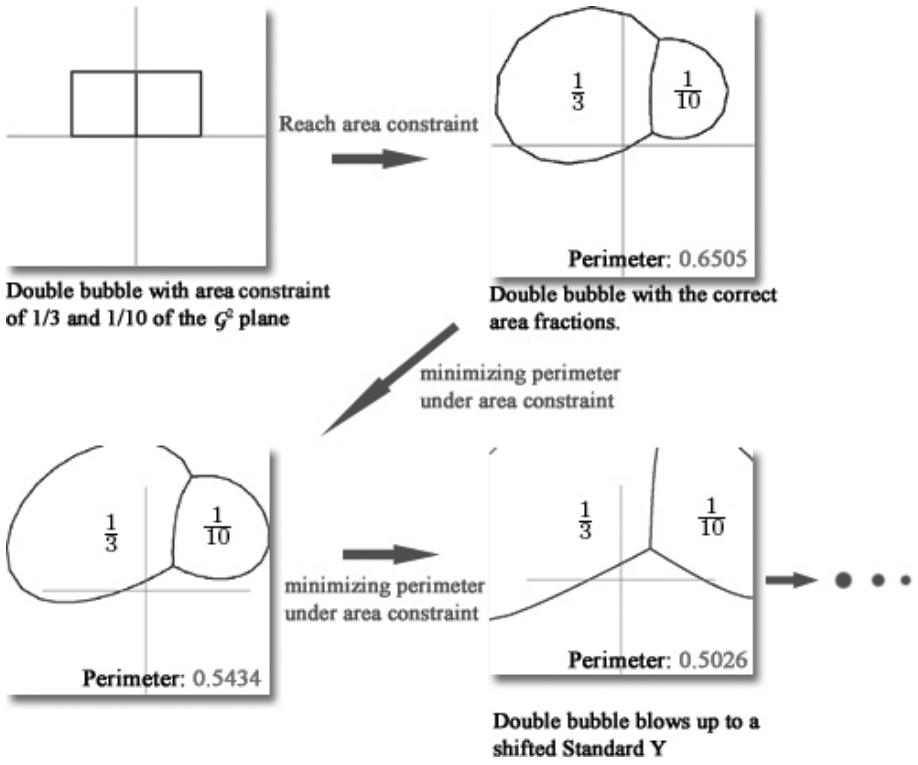

FIGURE 6. The evolution of an unequal-area double bubble in $G^2$.

*Remark.* Extending our work we propose the following conjecture.

**Conjecture 2.1.** *The perimeter-minimizing partition of $G^2$ into $n$ volumes $V_1 + V_2 + \ldots + V_n = 1$ consists of $n$ halflines and $n-3$ line segments, meeting at* 120 *degrees, as in Figure 7.*

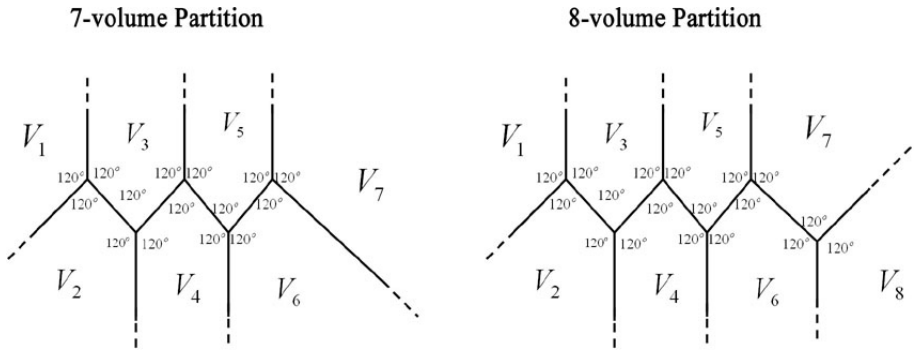

FIGURE 7. Our conjectured area-minimizing partition of $G^2$ into 7 and 8 volumes.

## 3. The Double Bubble Conjecture in $S^n$

Our main Theorem 3.7 shows that the unique area-minimizing partition of the sphere $S^n$ into three nearly equal volumes is a standard double bubble (see Definition 2). The main Lemmas 3.3–3.6 prove the Hutchings function positive in $G^m$, from which Theorem 3.7 follows. Section 3.3 extends Theorem 3.7 to a larger range of volumes.

A partial solution to the double bubble conjecture in $S^3$ obtained in [CF] states:

**Theorem 1.1.** *A least-area enclosure of two equal volumes in $S^3$ which add up to at most 90 percent of the total volume of $S^3$ must be the (unique) standard double bubble.*

Theorem 3.7 stems from this result.

### 3.1. The Hutchings Function in $G^m$ and $S^n$.

**Definition 3.** Define $T$ to be the triangular region in $R^3$ of positive volumes $(V_1, V_2, V_3)$ such that $V_1 + V_2 + V_3 = 1$. Throughout this section, unless otherwise noted, we assume that volumes $(V_1, V_2, V_3)$ are in $T$. Figures 8 and 9 illustrate this barycentric coordinate system.

**Definition 4.** The Hutchings function on the sphere $S^n$ is defined as

$$F_{S^n}(V_1, V_2, V_3) = 2A_{S^n}(V_1/2) + A_{S^n}(V_2) + A_{S^n}(V_3) - 2A_{S^n}(V_1, V_2, V_3),$$

where $A_{S^n}(v)$ denotes the surface area of the ball of volume fraction $v$ in $S^n(\sqrt{n})$ and $A_{S^n}(V_1, V_2, V_3)$ denotes the surface area of the standard double bubble which

partitions $S^n(\sqrt{n})$ into volume fractions $V_1, V_2, V_3$. Similarly, the Hutchings function in Gauss space $G^m$ is defined as

$$F_{G^m}(V_1, V_2, V_3) = 2A_{G^m}(V_1/2) + A_{G^m}(V_2) + A_{G^m}(V_3) - 2A_{G^m}(V_1, V_2, V_3),$$

where $A_{G^m}(v)$ denotes the surface area of a halfspace of $G^m$ of volume $v$ and $A_{G^m}(V_1, V_2, V_3)$ denotes the surface area of the standard Y which partitions $G^m$ into volumes $V_1, V_2, V_3$.

*Remark.* Hutchings ([Hu], Theorem 4.2) shows that if

$$F_{S^n}(V_1, V_2, V_3) > 0,$$

then the region of volume fraction $V_1$ is connected in an area-minimizing double bubble enclosing volume fractions $V_1, V_2, V_3$ in the sphere $S^n$. Hutchings actually uses a theoretically larger function, taking $A_{S^n}(V_1, V_2, V_3)$ to be the minimum area, so its positivity follows from the positivity of our $F_{S^n}$.

Note that the positivity of the Hutchings function is independent of the radius of $S^n$, since changing the radius scales the Hutchings function by a positive factor. The Hutchings theory does not apply directly to $G^m$, for lack of translational symmetry.

Cotton and Freeman ([CF], Proposition 7.3) show that for a minimizer in $S^n$, if each region and the exterior is connected, then the minimizer is a standard double bubble.

**Lemma 3.1.** *As $n$ approaches infinity, $F_{S^n}(V_1, V_2, V_3)$ approaches $F_{G^m}(V_1, V_2, V_3)$.*

PROOF. By Remark 2.2, $\lim_{n\to\infty} A_{S^n}(v) = A_{G^1}(v)$. By Proposition 2.12, $\lim_{n\to\infty} A_{S^n}(V_1, V_2, V_3) = A_{G^m}(V_1, V_2, V_3)$. Therefore,

$$F_G(V_1, V_2, V_3) = \lim_{n\to\infty} F_{S^n}(V_1, V_2, V_3).$$

□

*Remark.* Recall that $m$-dimensional Gauss space $G^m$ is $R^m$ endowed with density $(2\pi)^{-m/2}e^{-x^2/2}$. Let $(-\infty, x]$ be an interval of weighted length $v$ in $G^1$. Then

$$A_{G^1}(v) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$$

where $x$ is defined by

$$\int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt = v.$$

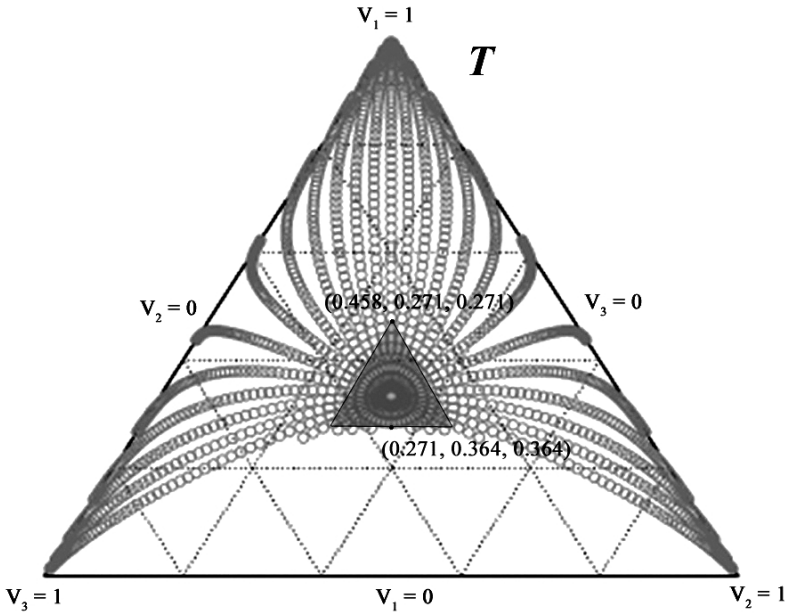

FIGURE 8. Small triangular region in $T$ where all three permutations of the Hutchings function are positive. The larger shaded region is where a particular one of them is positive; the small triangle is the intersection of three such regions.

Writing $A_{G^1}(v)$ as $e^{\psi(x)}$, observe that

$$\frac{dA_{G^1}(v)}{dv} = \frac{dA_{G^1}/dx}{dv/dx} = \psi'(x) = -x. \tag{1}$$

Therefore $A_{G^1}(v)$ is concave with maximum $A_{G^1}(1/2) = 1/\sqrt{2\pi}$.

**Definition 5.** Define the function $\tilde{F}_{S^n}(V_1, V_2, V_3)$, a lower bound of the Hutchings function $F_{S^n}(V_1, V_2, V_3)$, as

$$\tilde{F}_{S^n}(V_1, V_2, V_3) \quad = \quad 2A_{S^n}(V_1/2) + A_{S^n}(V_2) + A_{S^n}(V_3) - 3A_{S^n}\left(\frac{1}{2}\right).$$

Here $3A_{S^n}(1/2)$ arises as an overestimate for $2A_{S^n}(V_1, V_2, V_3)$ since three great $(n-1)$-hemispheres (each of which has area $A_{S^n}(1/2)/2$) meeting along a great $(n-2)$-sphere partition $S^n(\sqrt{n})$ into volume fractions $V_1, V_2, V_3$.

Similarly, define the function $\tilde{F}_G(V_1, V_2, V_3)$, a lower bound (for any $m$) of the Hutchings function $F_{G^m}(V_1, V_2, V_3)$, as

$$\tilde{F}_G(V_1, V_2, V_3) \quad = \quad 2A_{G^1}(V_1/2) + A_{G^1}(V_2) + A_{G^1}(V_3) - \frac{3}{\sqrt{2\pi}}.$$

Here $3/\sqrt{2\pi} = 3A_{G^1}(1/2)$ (as computed in Remark 3.1) arises as an overestimate of $2A_{G^m}(V_1, V_2, V_3)$. Indeed, except for the trivial case $m = 1$ three half-hyperplanes (each of which has area $A_{G^m}(1/2)/2$) meeting along an $(m-2)$-dimensional plane passing through the origin can partition $G^m$ into volumes $V_1, V_2, V_3$. Since the Gauss measure is a spherically symmetric product measure with total measure one, $A_{G^m}(v)$ is independent of $m$, so we can take $m = 1$.

**Lemma 3.2.** *As $n$ approaches infinity, $\tilde{F}_{S^n}(V_1, V_2, V_3)$ approaches $\tilde{F}_G(V_1, V_2, V_3)$.*

PROOF. By Remark 2.2, $\lim_{n\to\infty} A_{S^n}(v) = A_{G^1}(v)$. Therefore,

$$\tilde{F}_G(V_1, V_2, V_3) = \lim_{n\to\infty} \tilde{F}_{S^n}(V_1, V_2, V_3).$$

□

3.2. **Region of Positivity of the Hutchings Function.** Theorem 3.7 shows that the standard double bubble is an area minimizer for nearly equal volumes in $S^n$ for all $n$. The proof depends on the positivity of the Hutchings function $F_{S^n}$, which follows from the positivity of $F_{G^m}(V_1, V_2, V_3)$ and its permutations $F_{G^m}(V_2, V_3, V_1)$ and $F_{G^m}(V_3, V_1, V_2)$.

**Lemma 3.3.** *For equal volume fractions, $\tilde{F}_G$ is greater than* 0.029.

PROOF. Using $-100$ as an approximation for $-\infty$, we use numerical approximation to find $x$-values of $-.44$ and $-.97$ for terms of the Hutchings function applied to equal areas. Since

$$\int_{-100}^{-.97} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt < .16666 < \frac{1}{6}$$

and

$$\int_{-100}^{-.44} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt < .33333 < \frac{1}{3},$$

we have that

$$A_{G^1}(\frac{1}{6}) > \frac{1}{\sqrt{2\pi}} e^{-(-.97)^2/2} > .24922$$

and

$$A_{G^1}(\frac{1}{3}) > \frac{1}{\sqrt{2\pi}} e^{-(-.44)^2/2} > .36214.$$

Combining these inequalities yields

$$\begin{aligned} \tilde{F}_G\left(\frac{1}{3},\frac{1}{3},\frac{1}{3}\right) &= 2A_{G^1}\left(\frac{1}{6}\right) + A_{G^1}\left(\frac{1}{3}\right) + A_{G^1}\left(\frac{2}{3}\right) - \frac{3}{\sqrt{2\pi}} \\ &> 2(.24922) + 2(.36214) - \frac{3}{\sqrt{2\pi}} > .029. \end{aligned}$$

□

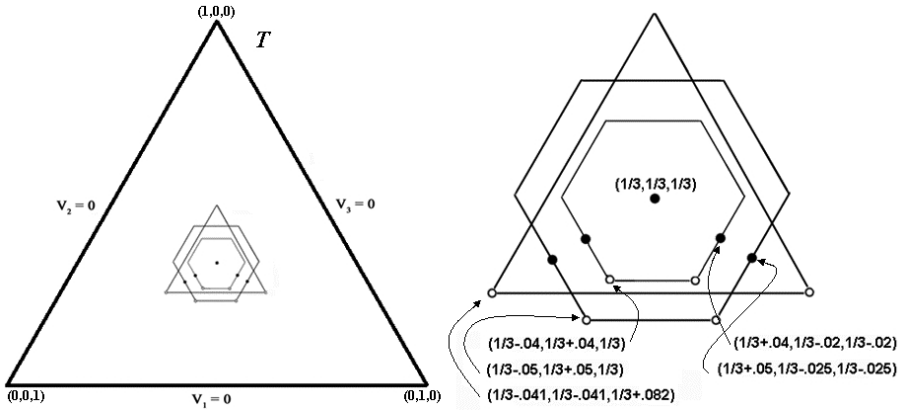

FIGURE 9. Small hexagons and triangle about $(1/3, 1/3, 1/3)$ where we prove the Hutchings function positive.

**Lemma 3.4.** *For a hexagon* $\{|V_i - 1/3| \le \delta \le 1/9\}$, $\tilde{F}_G(V_1, V_2, V_3)$ *is smallest at its two bottom vertices (with minimal* $V_1$ *as shown with the open circles in Figure 9). Similarly on a triangle* $\{1/3 - V_i \le \delta \le 1/18\}$ *the same result holds.*

PROOF. By Remark 3.1, $A_{G^1}$ is concave, hence so is $\tilde{F}_G$. Therefore $\tilde{F}_G$ attains its minimal value on the vertices of the hexagon and triangle.

We temporarily relax the constraint that $(V_1, V_2, V_3) \in T$. Then the partial derivatives of $\tilde{F}_G(V_1, V_2, V_3)$ are given by

$$\begin{aligned}\frac{\partial \tilde{F}_G}{\partial V_1} &= A'\left(\frac{V_1}{2}\right)\\ \frac{\partial \tilde{F}_G}{\partial V_2} &= A'(V_2)\\ \frac{\partial \tilde{F}_G}{\partial V_3} &= A'(V_3).\end{aligned}$$

By (1), $A'(V_1/2) = -x_1$, $A'(V_2) = -x_2$ and $A'(V_3) = -x_3$. Since $V_1/2 \leq 1/2$, $x_1$ is negative, and since $V_1/2$ is less than or equal to $V_2$ and $V_3$, therefore $x_1$ is less than or equal to $x_2$ and $x_3$. Thus for all $V_1, V_2, V_3$ in the hexagon,

$$\frac{\partial \tilde{F}_G}{\partial V_1} \geq \frac{\partial \tilde{F}_G}{\partial V_2}, \tag{2}$$

$$\frac{\partial \tilde{F}_G}{\partial V_1} \geq \frac{\partial \tilde{F}_G}{\partial V_3}. \tag{3}$$

Returning to $T$, for motion downward along the upper-righthand edge of the hexagon (as illustrated in Figure 9), $V_3$ is constant while $V_1$ decreases at the same rate that $V_2$ increases. Therefore by (2) $\tilde{F}_G$ is non-increasing. Similar analysis applies to the other non-horizontal edges. Therefore $\tilde{F}_G$ is smallest at the bottom vertices. For the triangle, the same argument applies. □

**Lemma 3.5.** *In the hexagon* $\{|V_i - 1/3| \leq .04\}$, $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$ *for large* $n$.

Proof. By Lemma 3.4, $\tilde{F}_G(V_1, V_2, V_3)$ achieves its minimum at $(1/3, 1/3, 1/3) + .04(-1, 1, 0)$. Computations show that

$$A_{G^1}\left(\frac{1}{6} - .02\right) > .24964, \quad A_{G^1}\left(\tfrac{1}{3} + .04\right) > .37866, \quad A_{G^1}\left(\frac{2}{3}\right) > .36359.$$

Hence,

$$\tilde{F}_G\left(\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) + .04(-1, 1, 0)\right) =$$

$$= 2A_{G^1}\left(\frac{1}{6} - .02\right) + A_{G^1}\left(\frac{1}{3} + .04\right) + A_{G^1}\left(\frac{2}{3}\right) - \frac{3}{\sqrt{2\pi}} > .004 > 0.$$

Thus in the hexagon $\{|V_i - 1/3| \leq .04\}$, $\tilde{F}_G(V_1, V_2, V_3) > 0$ and by Lemma 3.2, $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$ for large $n$. □

**Lemma 3.6.** *If $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$ for infinitely many n, then $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$ for all n.*

PROOF. By Barthe ([Bar], Proposition 11; see [Ros], Theorem 21),

$$\frac{A_{S^{(n+1)}}(v)}{A_{S^{(n+1)}}(\frac{1}{2})} \leq \frac{A_{S^n}(v)}{A_{S^n}(\frac{1}{2})}. \tag{4}$$

Dividing the modified Hutchings function by $A_{S^n}(1/2)$ yields

$$\frac{\tilde{F}_{S^n}(V_1, V_2, V_3)}{A_{S^n}(\frac{1}{2})} = \frac{A_{S^n}(V_1/2)}{A_{S^n}(\frac{1}{2})} + \frac{A_{S^n}(V_2)}{A_{S^n}(\frac{1}{2})} + \frac{A_{S^n}(V_3)}{A_{S^n}(\frac{1}{2})} - 3$$

By (4), $\tilde{F}_{S^n}(V_1, V_2, V_3)/A_{S^n}(1/2)$ is nonincreasing in n. The result follows. □

**Theorem 3.7.** *For all n, the $n-$dimensional standard double bubble is the unique area-minimizing partition of $S^n$ into any three volume fractions within .04 of 1/3.*

PROOF. By Lemma 3.5, for large $n$, $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$. By Lemma 3.6, for all $n$, $\tilde{F}_{S^n}(V_1, V_2, V_3) > 0$ and therefore $F_{S^n}(V_1, V_2, V_3) > 0$. By Hutchings (Remark 3.1) and the symmetry of permuting the $V_i$, each region is connected. By Cotton and Freeman (Remark 3.1), the regions must form a standard double bubble. □

**Corollary 3.8.** *In $G^m$ the standard Y is an area-minimizing partition for any three volume fractions within .04 of 1/3.*

PROOF. This follows immediately from Theorems 3.7 and 2.14. In fact, this result can be reached independent of Lemma 3.6 since it only depends on standard double bubbles with large $n$. □

3.3. **Extending the known region of positivity for the Hutchings function.** Using computational lower bounds on the Hutchings function we enlarge the known region of positivity for the Hutchings function in Gauss space and hence in high-dimensional spheres from the hexagon $\{|V_i - 1/3| \leq .04\}$ to $\{|V_i - 1/3| \leq .05\}$ and finally to the triangle $\{1/3 - V_i \leq .041\}$. (We do not know how to generalize Lemma 3.6 on lower-dimensional spheres.) Figure 9 shows the inner (.04) and outer (.05) hexagons along with the .041 triangle. An improved overestimate for $A_{G^m}(V_1, V_2, V_3)$ is necessary in order to extend the region of positivity . To this end we prove two lemmas about the concave nature of $A_{G^m}(V_1, V_2, V_3)$.

*Remark.* The concept of mean curvature can be generalized to hypersurfaces in manifolds with density, such as Gauss space ([Gr], [CHSX], [Mo2]). A first variation formula shows that the curvature $\kappa$ of a curve in an equilibrium configuration

equals minus the rate of change of perimeter or "area" with respect to volume transfer across the curve. A line in Gauss space has constant curvature equal to its signed distance from the origin (Remark 3.1).

**Lemma 3.9.** *In $T$, outside of the hexagon $\{|V_i - 1/3| < \delta\}$, $A_{G^m}(V_1, V_2, V_3)$ attains its maximum value at the middle of an edge.*

PROOF. Every candidate maximum point lies on the boundary of an expanded hexagon $\{|V_i - 1/3| \leq \delta_1\}$, for some $\delta_1 \geq \delta$. Consider moving along an edge of the hexagon. For example, hold $V_1$ constant while $V_2$ changes. By Remark 3.3, $-dA_{G^m}/dV_2$ is a signed distance which is strictly increasing by Lemma 2.9. Thus $dA_{G^m}/dV_2$ is strictly decreasing and hence $A_{G^m}$ is concave in $V_2$. By this concavity and symmetry we may assume that the candidate maximum point lies at the middle of an edge. Now consider holding $V_2 = V_3$ and changing $V_1$. By Remark 3.3, $-dA_{G^m}/dV_1$ is a signed distance which is strictly increasing by Lemma 2.10. Thus $dA_{G^m}/dV_1$ is strictly decreasing and hence $A_{G^m}$ is concave in $V_1$. By this concavity and symmetry, we may assume that $\delta_1 = \delta$. □

**Theorem 3.10.** *In $G^m$ the standard $Y$ is an area-minimizing partition for any three volume fractions within .05 of 1/3.*

PROOF. By Corollary 3.8, we need consider only the region $R$ between the outer hexagon (.05) and the inner hexagon (.04) of Figure 9. By Lemma 3.9 and the symmetry of the hexagon, we need consider only two edge midpoints

$$\begin{aligned} p_1 &= \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) + .04\left(-1, \frac{1}{2}, \frac{1}{2}\right), \\ p_2 &= \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) + .04\left(1, -\frac{1}{2}, -\frac{1}{2}\right). \end{aligned}$$

By computation $A_{G^m}(p_1)$ is approximately 0.596374, and $A_{G^m}(p_2)$ is approximately 0.596436. Therefore $A_{G^m}(V_1, V_2, V_3) \leq 0.596437$. Using this overestimate for $A_{G^m}(V_1, V_2, V_3)$ in region $R$, we define a modified $\tilde{F}_G$ (a new lower bound for $F_{G^m}$ in $R$), changing the constant term from $3/\sqrt{2\pi}$ to 0.596437. By Lemma 3.4, the lower bound for the $\tilde{F}_G$ in the outer hexagon occurs at $(1/3, 1/3, 1/3) + .05(-1, 1, 0)$. By computation this lower bound is approximately 0.0012288, and therefore $F_{G^m}$ is positive in region $R$.

By Lemma 3.1, $F_{S^n}(V_1, V_2, V_3)$ converges to $F_{G^m}(V_1, V_2, V_3)$. Therefore, for large n $F_{S^n}(V_1, V_2, V_3) > 0$. By symmetry of the hexagon, each $F_{S^n}(V_i, V_j, V_k)$ is positive. By Hutchings (Remark 3.1), each region, as well as its complement,

is connected. By Cotton and Freeman (Remark 3.1), the regions must form a standard double bubble in high-dimensional spheres. By Theorem 2.14, the minimizer in Gauss space is a standard Y. □

**Theorem 3.11.** *In $G^m$ the standard Y is an area-minimizing partition for any three volume fractions greater than or equal to* $1/3 - .041$.

Proof. By Corollary 3.8, we need consider only the region $R$ between the (.041) triangle and the outer hexagon (.05) of Figure 9. By Lemma 3.9 and the symmetry of the hexagon, we need consider only two edge midpoints

$$\begin{aligned} p_1 &= \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) + .05\left(-1, \frac{1}{2}, \frac{1}{2}\right), \\ p_2 &= \left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) + .05\left(1, -\frac{1}{2}, -\frac{1}{2}\right). \end{aligned}$$

By computation $A_{G^m}(p_1)$ is approximately 0.595213, and $A_{G^m}(p_2)$ is approximately 0.595334. Therefore $A_{G^m}(V_1, V_2, V_3) \leq 0.595335$. Using this overestimate for $A_{G^m}(V_1, V_2, V_3)$ in region $R$, we define a modified $\tilde{F}_G$ (a new lower bound for $F_{G^m}$ in $R$), changing the constant term from $3/\sqrt{2\pi}$ to 0.595335. By Lemma 3.4, the lower bound for the $\tilde{F}_G$ in the triangle occurs at $(1/3, 1/3, 1/3) + .041(-1, 2, -1)$. By computation this lower bound is approximately 0.0011504, and therefore $F_{G^m}$ is positive in region $R$.

As in the proof of Theorem 3.10, the minimizer in Gauss space is a standard Y. □

# Double Bubbles in $\mathbf{S}^3$ and $\mathbf{H}^3$

By *Joseph Corneli, Neil Hoffman, Paul Holt, George Lee, Nicholas Leger, Stephen Moseley, and Eric Schoenfeld*

*ABSTRACT. We prove the double bubble conjecture in the three-sphere* $\mathbf{S}^3$ *and hyperbolic three-space* $\mathbf{H}^3$ *in the cases where we can apply Hutchings theory:*

- *In* $\mathbf{S}^3$*, when each enclosed volume and the complement occupy at least 10% of the volume of* $\mathbf{S}^3$*;*
- *in* $\mathbf{H}^3$*, when the smaller volume is at least 85% that of the larger.*

*A balancing argument and asymptotic analysis reduce the problem in* $\mathbf{S}^3$ *and* $\mathbf{H}^3$ *to some computer checking. The computer analysis has been designed and fully implemented for both spaces.*

## 1. Introduction

In March of 2002, Hutchings, Morgan, Ritoré, and Ros [11] proved that the area-minimizing way to enclose and separate two given volumes in $\mathbf{R}^3$ is by a standard double bubble, defined as three spherical caps meeting in threes at 120 degree angles. In 2003, Cotton and Freeman [7] partially extended these methods to $\mathbf{S}^3$ and $\mathbf{H}^3$, proving that the standard double bubble is the most efficient way to enclose and separate two equal volumes with the added condition that in $\mathbf{S}^3$ the exterior of the double bubble takes up at least 10% of the volume of $\mathbf{S}^3$. More recently, Corneli et al. [3] have proved the double bubble conjecture in spheres of all dimensions provided the double bubble partitions the sphere into the nearly equal volumes.

Our main theorem in $\mathbf{S}^3$ (Theorem 6.3) improves upon Cotton and Freeman's results when $v$, $w$ are sufficiently large, showing that the standard double bubble is the least-area way to enclose and separate two regions of prescribed unequal volumes, whenever each region and the exterior contains at least ten percent of the total volume. In $\mathbf{H}^3$, our Main Theorem 6.4 improves upon the results of Cotton and Freeman, showing double bubbles are standard whenever the smallest region has volume at least 85% that of the larger region. Computer plots, Figures 1 and 2, show that this is approximately the largest range on which current methods of proof using the positivity of the Hutchings function can work. Indeed, the main focus of this article is rigorously proving that the Hutchings function is positive on most of the regions where it appears positive in these plots. The plots suggest that $F(v, w)$ is always positive when $v > w$. This fact is proved in Remark 2.11, answering the open question of Cotton and Freeman [7, Open Question 1.1].

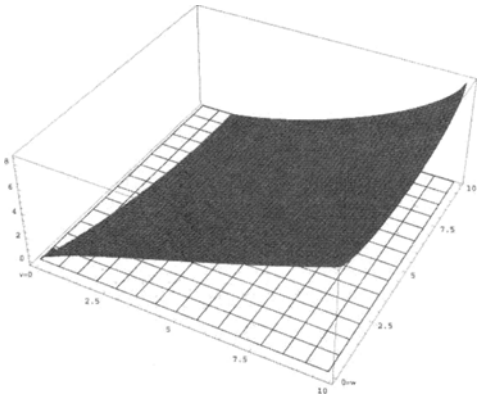

FIGURE 1 Plot of the Hutchings function $F(v, w)$ where it is positive in $\mathbf{S}^3$.

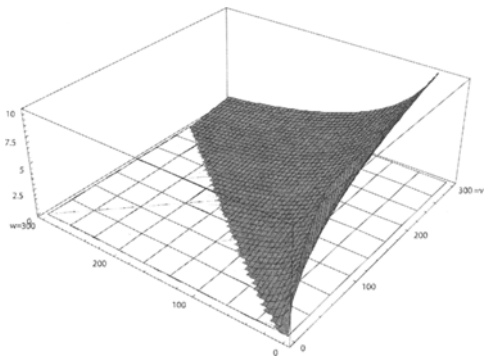

FIGURE 2 Plot of the Hutchings function $F(v, w)$where it is positive in $\mathbf{H}^3$.

**The proof.** The main difficulty is showing that both regions of a minimizing double bubble and the complement all have just one component each. Given such connectedness, Cotton and Freeman [7] extend the instability argument of [11] to show that a minimizing double bubble must be standard. By work of Hutchings [10], the first region in a minimizer of volumes $v$, $w$ is known to be connected if a certain "Hutchings function" $F(v, w)$, determined implicitly by integral formulas for volumes of spheres and standard double bubbles (see Definition 2.2) is positive. In their article, Cotton and Freeman use asymptotic analysis and intensive computation to verify this result along most of the line $v = w$ in $\mathbf{S}^3$ and all of the line $v = w$ in $\mathbf{H}^3$, thus proving that the standard double bubble is area-minimizing for equal volumes. For the two-dimensional domain of volumes $(v, w)$ in our unequal volume conjecture, the proof that $F(v, w) > 0$ is considerably harder. Sections 3 and 4 contain the requisite asymptotic analysis for the noncompact space $\mathbf{H}^3$. For small volumes, we use a Euclidean approximation (Section 3), and for large volumes we obtain the interesting result (Proposition 4.12) that

$$\lim_{w\to\infty} F(\psi w, w) = 2\pi \ln \frac{4(\psi+1)}{e^2},$$

which is positive if and only if $\psi > \lambda = e^2/4 - 1 < .85$. Along the line $v = \lambda w$, F is *decreasing* in $w$ when $w \geq 300$. Moreover, once $w > 150$, $\partial F/\partial v > 0$. This asymptotic analysis reduces the problem in $\mathbf{H}^3$ to a bounded domain. We are able to use a computer to show that the Hutchings function is positive on this bounded domain. In $\mathbf{S}^3$, which is a space of finite volume, our result requires each region to contain at least 10% of the total volume of $\mathbf{S}^3$, and we are again examining a bounded domain. Next we use a new balancing argument (Proposition 2.8), which says that if $F(\frac{v+w}{2}, \frac{v+w}{2})$ is positive, so is $F(v, w)$ for $v > 2w$. This argument, together with symmetry

(used only for $\mathbf{S}^3$) and a balancing argument due to Hutchings (Lemma 2.9), reduces the size of the domain to check. We then break up the domain into small rectangles (and triangles). Finally, we decompose the Hutchings function as the difference of a concave function and an increasing function, so that it suffices to consider the values on (or beyond) the corners of the rectangles (see Lemma 5.1). We find values of the parameters to locate such points and verify that $F(v, w) > 0$, allowing a safe margin of error. If necessary, we subdivide the rectangles and repeat the process.

Though using a computer introduces error, we bound this computation error and account for it in Section 5. For a complete version of the computer code, the reader is referred to [4].

## 2. The Hutchings function in $\mathbf{S}^3$ and $\mathbf{H}^3$

In $\mathbf{S}^3$ and $\mathbf{H}^3$, given volume $v$, a round ball has least boundary area $A(v)$ [14], [12, p. 127]. Similarly, given volumes $v$, $w$, there is an area-minimizing double bubble that encloses and separates these two volumes; furthermore, this double bubble is comprised of smooth constant-mean-curvature hypersurfaces, except possibly for a set of measure zero [12, Theorem 13.4, Remark before Proposition 13.8], [7, Proposition 2.3], and it is symmetric about some geodesic [10, Lemma 2.9, Remark 3.8]. Of course, in $\mathbf{S}^3$, we assume that $v, w$ satisfy $v + w < |\mathbf{S}^3|$, where $|\mathbf{S}^3|$ denotes the volume of $\mathbf{S}^3$. Also, we put $\bar{v}, \bar{w}, \bar{u}$ to be $v/|\mathbf{S}^3|$, $w/|\mathbf{S}^3|$, $u/|\mathbf{S}^3|$, respectively. Though the area of the area-minimizing double bubble is sometimes denoted $A(v, w)$ we reserve this notation for the area of the standard double bubble. The following argument shows $A(v, w)$ is well defined.

**Lemma 2.1** (Unique standard double bubble [7, Proposition 2.6] ). *Given volumes $v$ and $w$:*

- *Up to isometries of the space, there is a unique double bubble in $\mathbf{S}^3$ consisting of three spherical caps meeting at 120° that encloses and separates a region of volume $v$ and a region of volume $w$ (whenever $\bar{v} + \bar{w} < 1$).*
- *Up to isometries of the space, there is a unique double bubble in $\mathbf{H}^3$ consisting of two spheres (the outer caps) and a sphere, hyposphere, horosphere or geodesic plane (the inner cap) meeting at 120° that encloses and separates a region of volume $v$ and a region of volume $w$.*

***Definition 2.2.*** The *Hutchings function* in $\mathbf{S}^3$ is $F_{\mathbf{S}^3} : \{(v, w) : \bar{v} + \bar{w} < 1\} \to \mathbf{R}$, where

$$F_{\mathbf{S}^3}(v, w) = A_{\mathbf{S}^3}\left(\frac{v}{2}\right) + A_{\mathbf{S}^3}(w) + A_{\mathbf{S}^3}(v + w) - A_{\mathbf{S}^3}(v, w)\,, \tag{2.1}$$

and $A_{\mathbf{S}^3}(v, w)$ is the area of the standard double bubble.

The definition of $F_{\mathbf{H}^3}$ is similar.

We recall for the reader the basic property of the Hutchings function, namely that it can be used to limit the number of components in an area-minimizing double bubble.

**Proposition 2.3.** *In $\mathbf{S}^3$ or $\mathbf{H}^3$, if $F(v, w)$ is positive, then in an area-minimizing double bubble enclosing and separating volumes $v$ and $w$ the region of volume $v$ is connected.*

***Proof.*** This is a direct consequence of [7, Proposition 4.8] since the area of the standard double bubble has at least as much area as the area-minimizing double bubble. □

The argument given by Cotton and Freeman is essentially the same as the argument in $\mathbf{R}^n$ [12, p. 147], [10, Theorem 4.2].

Since each standard double bubble in $\mathbf{S}^3$ and $\mathbf{H}^3$ is symmetric about a geodesic line, it is convenient to compute area and volume of a standard double bubble by considering the revolution of some generating curve consisting of three circular arcs meeting at 120°. Figure 3 represents an arbitrary generating curve labeled with relevant measurements.

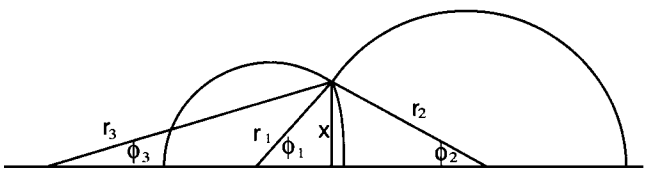

FIGURE 3 The generating curve for a standard double bubble.

Here we present the standard results on volume and surface area of spheres and double bubbles in $\mathbf{S}^3$ and $\mathbf{H}^3$.

***Remark 2.4.*** The formulas for surface area of a sphere of radius $r$ in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$A_{\mathbf{S}^3} = 4\pi \sin^2 r \text{ and } A_{\mathbf{H}^3} = 4\pi \sinh^2 r \,.$$

The volume formulas for a ball of radius $r$ in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$V_{\mathbf{S}^3} = \pi(2r - \sin 2r) \text{ and } V_{\mathbf{H}^3} = \pi(\sinh 2r - 2r) \,.$$

In $\mathbf{S}^3$ the area of a spherical cap subtended by an angle $2\phi_0$ is

$$\int_0^{2\pi} \int_0^{\phi_0} \sin^2 r \sin\phi \, d\phi \, d\theta = 2\pi \sin^2 r(1 - \cos\phi_0) \,. \tag{2.2}$$

The volume of a spherical cap that is subtended by an angle $2\phi_0$ is

$$-\pi\big(\tan^{-1}(\cos\phi_0 \tan r) - r\cos\phi_0 + (-1 + \cos\phi_0)(r - \cos r \sin r)\big) \,. \tag{2.3}$$

In $\mathbf{H}^3$ the area of a spherical cap in a sphere of radius $r$ subtended by an angle $2\phi_0$ is

$$\int_0^{2\pi} \int_0^{\phi_0} \sinh^2 r \sin\phi \, d\phi \, d\theta = 2\pi \sinh^2 r(1 - \cos\phi_0) \,. \tag{2.4}$$

The volume of a spherical cap in a sphere of radius $r$ subtended by an angle $2\phi_0$ is

$$\pi\big(-r + \tanh^{-1}(\cos\phi_0 \tanh r) - \cos\phi_0 \cosh r \sinh r + \cosh r \sinh r)\big)\big) \,. \tag{2.5}$$

Now we can compute the volume and areas of standard double bubbles.

For each bubble component, we compute the volume and area of the spherical cap which separates it from the exterior. To find the area of the double bubble, we simply add the area of the three spherical caps.

To compute the volume of the bubble components we add the volume contained by the separating cap to that contained by the smaller of the two outer cap to obtain the volume of the smaller region, and subtract the volume contained by the separating cap from that contained by the larger of the two outer cap to obtain the volume of the larger region. (Of course, when the two outer caps are the same size, the separating cap contains no volume so there is nothing to add or subtract.)

Examining Figure 3, we observe that the angle $\phi_1$ has a different orientation (relative to $r_2$ and $r_3$) depending on the relative size of the two bubbles. When $\phi_1$ is 90°, $r_2$ and $r_3$ are equal causing the volumes enclosed by both regions of the double bubble to be equal. Tracing back through the equations, we notice that this happens when

$$\frac{\tan(r_2) - \tan(r_1)}{\tan(r_2) + \tan(r_1)} = 1/3 \text{ (in } \mathbf{S}^3\text{) and } \frac{k_1 - k_2}{k_1 + k_2} = 1/3 \text{ (in } \mathbf{H}^3\text{)}. \tag{2.6}$$

We make adjustments to $\phi_1$ accordingly, and call the adjusted angle $\hat{\phi}_1$. Using this angle in the formulas for area and volumes of spherical caps yields the desired result, i.e., if $\hat{\phi}_1 > \frac{\pi}{2}$, the formulas return values corresponding to a cap smaller than a hemisphere, otherwise the values returned describe a cap that is larger than a hemisphere.

The concavity of $A(v)$ is well-known in both $\mathbf{S}^3$ and $\mathbf{H}^3$. Hutchings shows that the area of the area-minimizing double bubble enclosing volumes $v$ and $w$ is a concave function in both variables [10, Remark 3.8, Theorem 3.9]. For our computations, the concavity of the standard double bubble is relevant.

**Proposition 2.5.** *In* $\mathbf{S}^n$ *and* $\mathbf{H}^n$ *($n \geq 2$), $A(v, w)$ is a strictly concave function.*

***Proof.*** By uniqueness of standard double bubble (Lemma 2.1), it is the only equilibrium and hence the minimizer among spherical surfaces meeting along a sphere. Given $v_0$, $w_0$, and the standard double bubble, consider the area $A_1(v, w)$ of spherical double bubbles for nearby values of $v$ and $w$ obtained by varying the curvatures of the two bubbles, but leaving the curvature of the interface unchanged and giving up the 120-degree-angle condition. Along any line in $(v, w)$ space, if $v$ is strictly increasing, then the mean curvature $H_1$ of the first spherical cap is strictly decreasing, and similarly for $w$ and $H_2$. Hence, $A_1' = H_1\, dv/dt + H_2\, dw/dt$ is strictly decreasing and $A_1$ is strictly concave. Since $A(v, w) \leq A_1(v, w)$, with equality at $(v_0, w_0)$, $A(v, w)$ is strictly concave. □

The following two propositions follow directly from Proposition 2.5.

**Proposition 2.6.** *$A(v,w)$ in $\mathbf{S}^3$ is strictly increasing in $v$, $w$ on the closed triangular domain defined by $(0, 0)$, $(\frac{|\mathbf{S}^3|}{3}, \frac{|\mathbf{S}^3|}{3})$, $(0, \frac{|\mathbf{S}^3|}{2})$. Furthermore, $A(v, w)$ is also increasing on the line segment with end points $(0, \frac{|\mathbf{S}^3|}{2})$, $(\frac{|\mathbf{S}^3|}{3}, \frac{|\mathbf{S}^3|}{3})$.*

**Proposition 2.7.** *$A_{\mathbf{H}^3}(v, w)$ is strictly increasing in each variable.*

We call the following useful proposition "S-balancing" because it relies on the concavity of area of the standard double bubble, in contrast to Hutchings balancing (Lemma 2.9) which relies on the concavity of area of the minimizing double bubble.

**Proposition 2.8** (S-Balancing). *In $\mathbf{R}^n$, $\mathbf{H}^n$, or $\mathbf{S}^n$, for $n \geq 3$, if $w < v \leq 2w$ and $F(\frac{v+w}{2}, \frac{v+w}{2}) > 0$, then $F(v, w) > 0$.*

***Proof.*** By the concavity and symmetry of $A(x, y)$, we know

$$F(v, w) > 2A\left(\frac{v}{2}\right) + A(w) + A(v + w) - 2A\left(\frac{v + w}{2}, \frac{v + w}{2}\right). \tag{2.7}$$

Since $F\left(\frac{v+w}{2}, \frac{v+w}{2}\right) > 0$, to prove $F(v, w) > 0$ it suffices to show that

$$2A\left(\frac{v}{2}\right) + A(w) > 2A\left(\frac{v + w}{4}\right) + A\left(\frac{v + w}{2}\right). \tag{2.8}$$

But the concavity of $A(v)$ gives us that $f(x) = 2A(\frac{x}{2}) + A(v + w - x)$ is strictly increasing if $v + w$ is fixed and $x \in [\frac{v+w}{2}, \frac{2\cdot(v+w)}{3}]$. This shows Inequality (2.8), completing the proof. □

**Lemma 2.9** (Hutchings Balancing). ([10, Remark 3.8, Theorem 3.5, Corollary 3.9]). *In $\mathbf{R}^n$, $\mathbf{H}^n$, or $\mathbf{S}^n$, for $n \geq 3$, if $v > 2w$ (or in $\mathbf{S}^3$ if $v > 2u$), then the region of volume $v$ is connected.*

Permutation utilizes symmetries that exist with the Hutchings function when applied in compact spaces. Though this argument is applied in $\mathbf{S}^3$, it can be used in any space with finite volume that has a Hutchings function.

**Proposition 2.10** (Permutation). *In $\mathbf{S}^3$, $F(v, w) = F(v, u)$ where $u$ is the volume of the complement.*

***Proof.*** Notice $A(v, w) = A(v, u)$, $A(v+w) = A(u)$, and $A(w) = A(v+u)$. Thus, $F(v, w) = F(v, u)$. □

***Remark 2.11.*** S-balancing (Proposition 2.8), Hutchings balancing (Lemma 2.9), and permutation (Proposition 2.10) yield a complete answer to a question of Cotton and Freeman [7, Open Question 1]. In particular, the larger region of an area-minimizing double bubble in $\mathbf{H}^3$ is always connected. If $v > 2w$, this follows from Hutchings balancing (Lemma 2.9). Otherwise, connectedness follows from the positivity of the Hutchings function $F(v, w)$ (Proposition 2.3). This in turn follows from S-balancing (Proposition 2.8) and the positivity of the Hutchings function $F(v, v)$ for equal volumes [7, Propositions 5.11, 5.14, 5.19]. In $\mathbf{S}^3$, Hutchings balancing (Lemma 2.9) shows connectedness when $v > 2w$ or $v > 2u$. By Proposition 2.3, it suffices to show that $F(v, w) > 0$ if $w < v \leq 2w$ or $u < v \leq 2u$. If $\bar{v} \leq .4$, $F(v, v) > 0$ [7, Propositions 5.5, 5.8]. S-balancing (Proposition 2.8) shows that $F(v, w) > 0$ if $w < v \leq 2w$. Finally, permutation (Proposition 2.10) shows $F(v, w) > 0$ if $u < v \leq 2u$.

## 3. Positivity of the Hutchings function for small volumes in $\mathbf{H}^3$

**Theorem 3.1** (Double Bubble Theorem in $\mathbf{R}^3$ [11]). *The unique least-area enclosure of prescribed volumes $v$, $w$ in $\mathbf{R}^3$ is a standard double bubble.*

***Remark 3.2.*** For small prescribed volumes in $\mathbf{H}^3$, the space around any standard double bubble is nearly flat and looks like a portion of $\mathbf{R}^3$. By estimating the amount of distortion carefully, we can use information about the Hutchings function in $\mathbf{R}^3$ to prove that the Hutchings function in $\mathbf{H}^3$ is positive for certain prescribed volumes near 0. In the following proof, $\lambda$ is a constant which captures the amount of distortion, and $r$ represents the radius of a small ball in $\mathbf{H}^3$ which is only slightly affected by the curvature of $\mathbf{H}^3$.

**Lemma 3.3.** *For any pair of prescribed volumes less than* $(\frac{2\pi}{3} + \frac{\pi\sqrt{3}}{2})(\frac{2}{2+\sqrt{3}}r)^3$, *some minimizing double bubble in* $\mathbf{R}^3$ *enclosing those volumes fits inside a ball of radius* $r$.

***Proof.*** Without loss of generality assume that $v \leq w$ and fix $w$. The exterior spherical cap enclosing the region of volume $w$ has a radius, $r_w$. Consider standard double bubbles where the radius of this spherical cap is fixed at $r_w$. In this case, the equal volumes double bubble has the greatest diameter. However, the region enclosed by the spherical cap with radius $r_w$ has volume less than $w$. By increasing the radius until this region has volume $w$, the diameter increases. Thus for any nonequal volume double bubble enclosing volumes $v$ and $w$, where $v \leq w$, there will be a double bubble enclosing two regions of volume $w$ with a bigger diameter.

If $r_w$ is the radius of the spherical cap that forms the exterior of $W$, then the diameter of the equal volume double bubble is $2r_w + r_w\sqrt{3}$. So, this double bubble will fit inside a ball of radius $r > r_w\frac{(2+\sqrt{3})}{2}$.

We also know that in $\mathbf{R}^3$ a spherical cap of radius $r_0$ subtended by an angle $2\phi$ has volume:

$$V(r) = \frac{2\pi}{3}(r_0)^3 + \pi r_0{}^3\cos\phi\,. \tag{3.1}$$

Since $\phi \in [0, \frac{\pi}{6}]$,

$$w \leq (r_w)^3\Big(\frac{2\pi}{3} + \frac{\pi\sqrt{3}}{2}\Big)\,. \tag{3.2}$$

Substituting $\frac{2}{2+\sqrt{3}}r$ for $r_w$ in the above inequality gives the desired result. □

**Lemma 3.4.** *If* $.84w \leq v \leq w$, *then*

$$2A_{\mathbb{R}^3}\Big(\frac{v}{2}\Big) + A_{\mathbb{R}^3}(w) + A_{\mathbb{R}^3}(v+w) > (2.02676)A_{\mathbb{R}^3}(v, w)\,. \tag{3.3}$$

***Proof.*** (Modification of [11, Proposition 6.2]). By rescaling, we may assume that $v = 1 - w$ and that $w \in [\frac{1}{2}, \frac{1}{1.84}]$. As $A_{\mathbb{R}^3}(v, w)$ is concave [10, Theorem 3.2], we have

$$A_{\mathbb{R}^3}(1-w, w) \leq A_{\mathbb{R}^3}\big(\tfrac{1}{2}, \tfrac{1}{2}\big) = \big(2^{-\frac{4}{3}}\cdot 3\big)A_{\mathbb{R}^3}(1)\,.$$

Hence, it suffices to prove that

$$2A_{\mathbb{R}^3}\big(\tfrac{1-w}{2}\big) + A_{\mathbb{R}^3}(w) + A_{\mathbb{R}^3}(1) \geq 2.02676\big(2^{-\frac{4}{3}}\cdot 3\big)A_{\mathbb{R}^3}(1)\,,$$

which follows from the concavity of the left-hand side. □

**Proposition 3.5.** *If* $0 < v, w < .002743$ *and* $.84w \leq v \leq w$, *then*

$$2A_{\mathbf{H}^3}\Big(\frac{v}{2}\Big) + A_{\mathbf{H}^3}(w) + A_{\mathbf{H}^3}(v+w) - 2A_{\mathbf{H}^3}(v, w) > 0\,. \tag{3.4}$$

***Proof.*** By Lemma 3.3, we can fit a double bubble in $\mathbf{R}^3$ with prescribed volumes $v, w < .002743$ in a ball $B$ of radius $r < .1547$.

For ease of notation let $\lambda = \frac{\sinh r}{r} < 1.003994$.

Notice that if this ball can enclose a standard double bubble of volumes $(\lambda^{-2}v, \lambda^{-2}w)$ then it can enclose spheres of volumes:
$\{\lambda^{-2}\frac{v}{2}, \lambda^{-2}w, \lambda^{-2}(v+w)\}$. We may estimate the surface area of any sphere in $\mathbf{R}^3$ which fits inside $B$. Suppose that a sphere enclosing volume $\lambda^{-2}\alpha$ fits inside $B$; in particular, this holds for $\alpha \in \{\frac{v}{2}, w, (v+w)\}$. The single bubble in $\mathbf{H}^3$ encloses a volume $\alpha' \leq \alpha$ and has surface area at least $A_{\mathbf{R}^3}(\lambda^{-2}\alpha)$. Thus,

$$A_{\mathbf{H}^3}(\alpha) \geq A_{\mathbf{R}^3}\left(\lambda^{-2}\alpha\right). \tag{3.5}$$

Therefore,

$$\begin{aligned} &2A_{\mathbf{H}^3}\left(\frac{v}{2}\right) + A_{\mathbf{H}^3}(w) + A_{\mathbf{H}^3}(v+w) \\ &\quad \geq 2A_{\mathbf{R}^3}\left(\lambda^{-2}v/2\right) + A_{\mathbf{R}^3}\left(\lambda^{-2}w\right) + A_{\mathbf{R}^3}\left(\lambda^{-2}(v+w)\right). \end{aligned} \tag{3.6}$$

By Lemma 3.4,

$$2A_{\mathbf{R}^3}\left(\frac{\lambda^{-2}v}{2}\right) + A_{\mathbf{R}^3}\left(\lambda^{-2}w\right) + A_{\mathbf{R}^3}\left(\lambda^{-2}(v+w)\right) \geq (2.02676)A_{\mathbf{R}^3}\left(\lambda^{-2}v, \lambda^{-2}w\right). \tag{3.7}$$

Scaling of double bubbles in $\mathbf{R}^3$ tells us

$$A_{\mathbf{R}^3}\left(\lambda^{-2}v, \lambda^{-2}w\right) = (\lambda)^{-4/3}A_{\mathbf{R}^3}(v, w). \tag{3.8}$$

Because $B$ contains some minimizing double bubble $\Sigma_1$ in $\mathbf{R}^3$ enclosing volumes $v, w$, we can estimate the surface area of the image of $\Sigma_1$ in $\mathbf{H}^3$. This double bubble $\Sigma_2$ encloses volumes $v_2 \geq v$ and $w_2 \geq w$, with surface area less than or equal to $A_{\mathbf{R}^3}(v_2, w_2)\lambda^2$. Therefore,

$$A_{\mathbf{R}^3}(v, w) \geq \lambda^{-2}A_{\mathbf{H}^3}(v_2, w_2). \tag{3.9}$$

By Proposition 2.7, $A_{\mathbf{H}^3}(x, y)$ is increasing in each variable, implying that

$$A_{\mathbf{H}^3}(v_2, w_2) \geq A_{\mathbf{H}^3}(v, w). \tag{3.10}$$

Combining inequalities (3.6), (3.7), (3.9), and (3.10) with equality (3.8) gives

$$2A_{\mathbf{H}^3}\left(\frac{v}{2}\right) + A_{\mathbf{H}^3}(w) + A_{\mathbf{H}^3}(v+w) \geq (2.0676)(\lambda)^{-10/3}A_{\mathbf{H}^3}(v, w). \tag{3.11}$$

The desired result follows from the inequality $(2.02676)\lambda^{-10/3} > 2$. □

***Remark 3.6*** (Notes on $\mathbf{S}^3$). Although we are only concerned with volumes greater than 10% of the volume $\mathbf{S}^3$, the above argument works in $\mathbf{S}^3$ with a distortion factor, $\lambda = \frac{\sin r}{r}$. Otherwise the proof follows with very little adjustment. Using Lemma 3.4, the Hutchings Function is positive for small volumes in $\mathbf{S}^3$ namely $v, w < 0.002738$ and $.84w \leq v \leq w$.

## 4. Positivity of the Hutchings function for large volumes in $\mathbf{H}^3$

Theorem 4.21 shows that for sufficiently large $v$ and $w$, the Hutchings function in $\mathbf{H}^3$ is positive whenever $\psi = v/w \geq \lambda$ and $w \geq 300$. (Throughout this section we set $\lambda = e^2/4 - 1$.) The proof of Theorem 4.21 uses three ancillary results.

Proposition 4.12. *For a fixed ratio $v/w$, the limit of the Hutchings function as $w \to \infty$ is nonnegative if and only if $\psi \geq \lambda < .85$.*

Proposition 4.18. *The Hutchings function strictly decreases if one travels outward along the line* $v = \lambda w$ *as long as* $w > 300$.

Lemma 4.20. *For any fixed* $w \geq 150$ *and* $v \geq \lambda w$, $\frac{\partial F}{\partial v} > 0$.

Together, these results show that the Hutchings function is positive for $\psi \geq \lambda$ and $w > 300$. In order to prove Proposition 4.12, we must describe the limits of various quantities for standard double bubbles enclosing volumes $v$, $w$ as $v$, $w$ grow large. Proving Proposition 4.18 and Lemma 4.20 requires a closer examination of how fast these quantities converge to their limits. So, the results about the limits appear alongside various inexact numerical estimates.

If $r = r(v)$ is the radius of a sphere with volume $v$, then

$$r > \frac{1}{2} \ln \frac{2v}{\pi} . \tag{4.1}$$

**Lemma 4.1.** *If* $r = r(v)$ *is the radius of a sphere with volume* $v$, *then*

$$\lim_{v \to \infty} \left( r - \frac{1}{2} \ln \frac{2v}{\pi} \right) = 0 . \tag{4.2}$$

***Proof.*** By manipulation of the volume formula,

$$\frac{2v}{\pi} \left( e^{2(r - \frac{1}{2} \ln \frac{2v}{\pi})} - 1 \right) = e^{-2r} + 4r . \tag{4.3}$$

Notice for any $\epsilon > 0$ we can find a sufficiently large $r$, such that,

$$e^{-2r} + 4r < 2(\sinh 2r - 2r)\left(e^{2\epsilon} - 1\right) . \tag{4.4}$$

Hence, $\frac{2v}{\pi}(e^{2(r - \frac{1}{2} \ln \frac{2v}{\pi})} - 1) < \frac{2v}{\pi}(e^{2\epsilon} - 1)$ and $2(r - \frac{1}{2} \ln \frac{2v}{\pi}) < 2\epsilon$, as needed. □

***Remark 4.2.*** When $v > 150\lambda > \pi(\sinh(4.4) - 4.4)$, we have $r > 2.2$ and Inequality (4.4) holds for $\epsilon = 0.06$. Thus, $r < \frac{1}{2} \ln \frac{2v}{\pi} + .06$ for such $v$. We obtain the following numerical estimate: If $v > 150\lambda < 127.09$, then $r < \frac{1}{2} \ln \frac{2v}{\pi} + .06$.

**Lemma 4.3.** *As* $v \to \infty$, $A(v)$ *tends to* $2v + 2\pi \ln v - 2\pi(1 - \ln(\pi/2))$.

***Proof.*** Let $r = r(v)$ denote the radius of a sphere with volume $v$. Since

$$r = \frac{1}{2} \ln \left( \frac{2v}{\pi} + e^{-2r} + 4r \right) , \tag{4.5}$$

we see that,

$$A(v) = 2v - 2\pi + 2\pi e^{-2r} + 4\pi r . \tag{4.6}$$

By Lemma 4.1,

$$\lim_{v \to \infty} r - \frac{1}{2} \ln \frac{2v}{\pi} = \lim_{v \to \infty} r - \frac{1}{2} \ln v + \frac{1}{2} \ln \frac{\pi}{2} = 0 . \tag{4.7}$$

Also, $\lim_{v \to \infty} e^{-2r} = 0$. The desired result follows easily. □

**Lemma 4.4.** *The curvature of a sphere with volume $v$ and radius $r$ is*

$$2 + \frac{2\pi}{v + 2\pi r + \frac{\pi}{2}e^{-2r} - \pi/2}\,. \tag{4.8}$$

***Proof.*** This holds since the curvature is $2\coth r$ and $2v/\pi = e^{2r} - e^{-2r} - 4r$. □

**Lemma 4.5.** $A'(x) < 2 + \frac{2\pi}{x+\pi\ln x - 3}$.

***Proof.*** From (4.1) we have the following bound on the radius $r$ of a sphere containing volume $x$:

$$r > \frac{1}{2}\ln(2x/\pi) = \frac{1}{2}\ln x + (1/2)\ln(2/\pi) \tag{4.9}$$

$$> \frac{1}{2}\ln x - 3/2\pi + 1/4\,. \tag{4.10}$$

By Lemma 4.4,

$$A'(x) = 2 + \frac{2\pi}{x + 2\pi r + (\pi/2)e^{-2r} - \pi/2}\,. \tag{4.11}$$

Also, $e^{-2r} > 0$. Applying these inequalities in the above expression for $A'(x)$ yields the desired result. □

**Lemma 4.6.** *If $x > 150\lambda$, then $A'(x) > 2 + \frac{2\pi}{x+\pi\ln x - 1.041}$.*

***Proof.*** By Lemma 4.4,

$$A'(v) = 2 + \frac{2\pi}{v + 2\pi r + \frac{\pi}{2}e^{-2r} - \frac{\pi}{2}}\,. \tag{4.12}$$

Notice, $\frac{\pi}{2}e^{-2r} - \frac{\pi}{2} < 0$. Also, we have $r < \frac{1}{2}\ln\frac{2v}{\pi} + 0.06$ because $v > 150\lambda$ (Remark 4.2). Hence,

$$2\pi r < \pi\ln\frac{2v}{\pi} + 0.12\pi = \pi\ln v + \pi\ln\frac{2}{\pi} + 0.12\pi < \pi\ln v - 1.041\,. \tag{4.13}$$

With these approximations, we find

$$A'(v) > 2 + \frac{2\pi}{v + \pi\ln v - 1.041}\,. \tag{4.14}$$ □

**Corollary 4.7.** *If $x > 300\lambda$ then $A'(x+3) > 2 + \frac{2\pi}{x+\pi\ln x + 2}$.*

***Proof.*** By Lemma 4.6, $A'(x) > 2 + \frac{2\pi}{x+\pi\ln x - 1.041}$, if $x > 150\lambda$.

Consider the denominator of the fraction in (4.8). Because $e^{-2r} < 1$, the third term minus $\pi/2$ is less than 0. We now approximate the second term. By Remark 4.2, we have $r < \frac{1}{2}\ln\frac{2v}{\pi} + 0.06$ because $v > 150\lambda$. Hence, the second term satisfies

$$2\pi r < \pi\ln\frac{2v}{\pi} + 0.12\pi = \pi\ln v + \pi\ln\frac{2}{\pi} + 0.12\pi < \pi\ln v - 1.041\,. \tag{4.15}$$

With these approximations, we find

$$A'(v) > 2 + \frac{2\pi}{v + \pi \ln v - 1.041} . \tag{4.16}$$

For $x > 300\lambda$, we have

$$\pi \ln \frac{x+3}{x} - 1.041 < -1.004 . \tag{4.17}$$

Hence,

$$A'(x+3) > 2 + \frac{2\pi}{x + 3 + \pi \ln x - 1.004} > 2 + \frac{2\pi}{x + \pi \ln x + 2} . \qquad \square \tag{4.18}$$

**Lemma 4.8.** *Given a standard double bubble, the radius of the circular interface where the three caps meet is less than* $\cosh^{-1}(2)$.

***Proof.*** Let $D$ be the disk whose boundary is the circular interface. Let $y$ be the radius of $D$. $D$ meets the bigger of the outer caps of the double bubble at an angle $\alpha \geq 2\pi/3$. The radii of this outer cap and $D$ come together at an angle of $\beta \geq \pi/6$ along the circular interface. Let $2\phi_o$ be the angle that subtends this cap. By the formula for the area of a spherical cap in $\mathbf{H}^3$ [Equation (2.4)] and the hyperbolic laws of cosines and sines the surface area of the outer cap is

$$\frac{2\pi \sinh^2 y}{1 - \cosh y \sin \beta} . \tag{4.19}$$

The surface area of this cap is positive and finite, implying that $\cosh y < \csc \beta \leq \csc(\pi/6) = 2$. Because $t \mapsto \cosh t$ is increasing for $t > 0$, $y < \cosh^{-1}(2)$. $\square$

**Lemma 4.9.** *Given a spherical cap subtended by an angle of* $2\phi$ *on a sphere of radius* $r$, *let* $\theta$ *be the angle the sphere makes with the disk of radius* $y$ *that shares a boundary with the spherical cap. The volume of this cap can be expressed as,*

$$\pi \left( \frac{\sinh y \sin\theta}{sech\, y + \cos\theta} - \tanh^{-1}\left( \frac{\sinh y \sin\theta}{\cosh y + \cos\theta} \right) \right) . \tag{4.20}$$

***Proof.*** This follows from using the identities:

$$\begin{aligned}
\tanh(a+b) &= \frac{\tanh a + \tanh b}{1 + \tanh a \tanh b} \text{ where } (a+b) = \left( -r + \tanh^{-1}(\tanh r \cos\phi) \right) , \\
1 - \tanh^2 x &= \operatorname{sech}^2 x \text{ and } \cosh b = \frac{\sin\phi}{\cos\gamma} , \\
\cosh c &= \cosh y \cosh b , \\
\cos\gamma &= \sin\phi \cosh b , \\
\tanh r \cos\gamma &= \tanh y, \cosh y \sin\gamma = \cos\phi , \\
\sinh y &= \sin\phi \sinh r \text{ and } \cos\gamma = \frac{\tanh y}{\tanh r}, \text{ and} \\
\sin\phi &= \frac{\sinh y}{\sinh r} .
\end{aligned}$$

$\square$

**Lemma 4.10.** *Given a standard double bubble enclosing volumes $v, w$, let $\theta$ be the angle between the separating cap and the disk, D, with the same boundary, and let $y$ be the radius of D. As $v, w$ grow large, $\theta \to 0$ and $y \to \cosh^{-1}(2)$.*

***Proof.*** By Lemma 4.8, $y < \cosh^{-1}(2)$. The two caps of the region containing D meet D at angles $\theta \in [0, \pi/3)$ and $\alpha = 2\pi/3 - \theta$. Put $x$ to be the volume of this region. Using the volume formulas we see

$$x < \pi \left( \frac{\sinh y \sin \alpha}{\operatorname{sech} y + \cos \alpha} + \frac{\sinh y \sin \theta}{\operatorname{sech} y + \cos \theta} \right) . \tag{4.21}$$

Since $\operatorname{sech} y > 1/2$ and $\cos\theta, \cos\alpha > -1/2$,

$$\begin{aligned} x &< \pi \left( \frac{\sinh\left(\cosh^{-1}(2)\right) \sin(\pi/2)}{\operatorname{sech} y + \cos \theta} + \frac{\sinh\left(\cosh^{-1}(2)\right) \sin(\pi/2)}{\operatorname{sech} y + \cos \alpha} \right) \\ &< \frac{2\pi\sqrt{3}}{\operatorname{sech} y + \cos(2\pi/3 - \theta)} . \end{aligned}$$

As $v, w$ approach infinity, $x \geq \min\{v, w\}$ must approach infinity as well, implying that the positive quantity $\operatorname{sech} y + \cos(2\pi/3 - \theta)$ must approach 0—that is, $y$ must approach $\cosh^{-1}(2)$, and $\cos(2\pi/3 - \theta)$ must approach $-\frac{1}{2}$. Because $2\pi/3 - \theta \in (\pi/3, 2\pi/3]$, $\theta$ must approach 0. In particular, when $v, w > x_0 = 300\lambda$, we have

$$x_0 < \frac{2\pi\sqrt{3}}{\operatorname{sech} y + \cos(2\pi/3 - \theta)} < \frac{2\pi\sqrt{3}}{1/2 + \cos(2\pi/3 - \theta)} \tag{4.22}$$

or

$$\cos(2\pi/3 - \theta) < \frac{2\pi\sqrt{3}}{x_0} - 1/2 < -.457 . \tag{4.23}$$

For $\theta \in [0, \pi/3)$, this is true only if $\theta < 1/20$. □

Note, the following numerical estimate: If $v, w > 300\lambda \approx 254.18$, then $\theta < 1/20$.

**Lemma 4.11.** *As $v, w$ grow large, the surface area of a standard double bubble enclosing volumes $v, w$ approaches*

$$A_{\mathbf{H}^3}(v + v_\infty) + A_{\mathbf{H}^3}(w + v_\infty) - 2a_\infty + c_\infty \tag{4.24}$$

*where $v_\infty = \pi(3/2 - \ln 2)$, $a_\infty = 3\pi$, and $c_\infty = 2\pi$.*

***Proof.*** Given a standard double bubble enclosing volumes $v, w$, consider the region enclosing volume $v$. Its outer cap lies on a sphere; let the volume of this sphere be $v + v^{(1)}_{v,w}$ and let the surface area of the sphere exceed that of the outer cap by $a^{(1)}_{v,w}$. Define $v^{(2)}_{v,w}$ and $a^{(2)}_{v,w}$ similarly with respect to the region enclosing volume $w$. Finally, let $c_{v,w}$ denote the surface area of the separating cap. Then the surface area of the standard double bubble is

$$A_{\mathbf{H}^3}\left(v + v^{(1)}_{v,w}\right) + A_{\mathbf{H}^3}\left(w + v^{(2)}_{v,w}\right) - a^{(1)}_{v,w} - a^{(2)}_{v,w} + c_{v,w} . \tag{4.25}$$

Suppose that $\theta$ is the angle between the separating cap and the disk with the same boundary, and let $y$ be the radius of the disk. By Lemma 4.10, as $v$ and $w$ grow large, $\theta \to 0$ and

$y \to y_0 = \cosh^{-1}(2)$. Using formulas for volume and surface area, one can easily check that

$$\lim_{v,w\to\infty} v^{(1)}_{v,w} = \lim_{v,w\to\infty} v^{(2)}_{v,w} = \pi\left(\frac{\sinh y_0 \sin(\pi/3)}{\operatorname{sech} y + \cos(\pi/3)} - \tanh^{-1}\left(\frac{\sinh y_0 \sin(\pi/3)}{\cos y + \cos(\pi/3)}\right)\right) = v_\infty$$

$$\lim_{v,w\to\infty} a^{(1)}_{v,w} = \lim_{v,w\to\infty} a^{(2)}_{v,w} = \frac{2\pi \sinh^2 y_0}{1+\cos(\pi/3)\cosh y_0} = a_\infty$$

and

$$\lim_{v,w\to\infty} c_{v,w} = \frac{2\pi \sinh^2 y_0}{1+\cos 0 \cosh y_0} = c_\infty .$$

Hence,

$$\left|A\left(v + v^{(1)}_{v,w}\right) - A(v+v_\infty)\right| < A'(v)\left|v^{(1)}_{v,w} - v_\infty\right|$$

approaches 0 as $v$, $w$ grow large. So too does $|A(w+v^{(2)}_{v,w}) - A(w+v_\infty)|$. From these computed limits, it follows that the surface area of the standard double bubble enclosing volumes $v$, $w$—as calculated in Equation 4.25—approaches $A(v+v_\infty)+A(w+v_\infty)-2a_\infty+c_\infty$ as $v$, $w$ get large. □

**Proposition 4.12.** *For each fixed* $\psi > 0$, $\lim_{w\to\infty} F(\psi w, w) = 2\pi \ln \frac{4(\psi+1)}{e^2}$.

***Proof.*** We write $v = v(w) = \lambda w$. Let $v_\infty = \pi(3/2 - \ln 2)$, $a_\infty = 3\pi$, and $c_\infty = 2\pi$. By Lemma 4.11, the given limit equals

$$\lim_{w\to\infty} 2A\left(\frac{v}{2}\right) + A(w) + A(v+w) - 2(A(v+v_\infty) + A(w+v_\infty) - 2a_\infty + c_\infty) \tag{4.26}$$

provided that the latter limit exists. By Lemma 4.3,

$$\lim_{x\to\infty} A(x) = 2x + 2\pi \ln x - 2\pi(1 - \ln(\pi/2)) \tag{4.27}$$

for $x \in \{\frac{v}{2}, w, v+w, 2v+v_\infty, w+v_\infty\}$. Substituting these expressions into (4.26) and simplifying gives

$$\lim_{w\to\infty}\left(2\pi\left(2\ln\left(\frac{v}{2}\right)+\ln w+\ln(v+w)-2\ln(v+v_\infty)-2\ln(w+v_\infty)\right) - 8v_\infty+4a_\infty-2c_\infty\right)$$

provided that this new limit exists. Indeed, this new limit does exist and equals

$$\begin{aligned}
&\lim_{w\to\infty}\left(2\pi \ln\left(\frac{v^2 w(v+w)}{4(v+v_\infty)^2(w+v_\infty)^2}\right) - 8v_\infty + 4a_\infty - 2c_\infty\right)\\
&= \lim_{w\to\infty}\left(2\pi\ln\left(\frac{v+w}{4w}\right) - 8v_\infty + 4a_\infty - 2c_\infty\right)\\
&= 2\pi \ln\left(\frac{4(\psi+1)}{e^2}\right).
\end{aligned}$$

Hence, the limit in Equation (4.26) evaluates to $2\pi \ln(\frac{4(\psi+1)}{e^2})$. □

(Note that this limit is nonnegative if and only if $\psi \geq \lambda < 0.85$.)

**Lemma 4.13.** *Given a standard double bubble enclosing volumes* $v$, $w$, *the outer cap of the region of volume* $v$ *lies on a sphere, say with volume* $v + v_1$ *(resp. the outer cap of the region of volume* $w$ *lies on a sphere with volume* $w + w_1$*). If* $v, w > 300\lambda$ *then* $v_1, w_1 < 3$.

***Proof.*** Let $\mathrm{vol}(y, \alpha)$ denote the volume of a spherical cap with associated disk of radius $y$, where the cap and disk meet at an angle $\alpha \in [0, \pi]$. This volume is increasing in both $y$ and $\alpha$. Without loss of generality, assume that $v \leq w$. The three caps of the standard double bubble meet along a circular interface with radius $y_0$; let the disk with this circle as its boundary meet the separating cap of the double bubble at angle $\theta$. By Lemma 4.8, $y_0 < \cosh^{-1}(2)$. By Lemma 4.10, $\theta < 1/20$. Both $v_1 = \mathrm{vol}(y_0, \pi/3 + \theta) - \mathrm{vol}(y_0, \theta)$ and $w_1 = \mathrm{vol}(y_0, \pi/3 - \theta) + \mathrm{vol}(y_0, \theta)$ are less than $\mathrm{vol}(y_0, \pi/3 + \theta) + \mathrm{vol}(y_0, \theta)$, which in turn is less than $\mathrm{vol}(\cosh^{-1}(2), \pi/3 + 1/20) + \mathrm{vol}(\cosh^{-1}(2), 1/20) < 3$. □

We now prove some algebraic lemmas that will be used in the proof of Proposition 4.18 and later in Proposition 4.19.

**Lemma 4.14.** *For positive numbers $\mu$, $w$ with $\ln \mu + a > 0$*

$$\frac{\mu}{\mu w + \pi \ln(\mu w) + a} > \frac{1}{w} - \frac{1}{w^2}\left(\frac{\pi \ln w}{\mu} + \frac{\pi \ln \mu}{\mu} - \frac{a}{\mu}\right). \tag{4.28}$$

***Proof.*** If $\pi \ln x + a > 0$, then

$$\frac{1}{x + \pi \ln x + a} > \frac{1}{x} - \frac{\pi \ln x + a}{x^2}. \tag{4.29}$$

Making the substitution $x = \mu w$ yields the desired result. □

**Lemma 4.15.** *For positive $\mu$, $w$ , with $\mu w > 150$*

$$\frac{\mu}{\mu w + \pi \ln(\mu w) - 3} < \frac{1}{w} - \frac{1}{w^2}\left(\frac{\pi \ln w}{1.1\mu} + \frac{\pi \ln \mu}{1.1\mu} - \frac{3}{1.1\mu}\right). \tag{4.30}$$

***Proof.*** If $x > 150\lambda$, we have $1.1x > x + \pi \ln x - 3 > 0$. Hence,

$$\frac{1}{x + \pi \ln x - 3} = \frac{1}{x} - \frac{\pi \ln x - 3}{x(x + \pi \ln x - 3)} < \frac{1}{x} - \frac{\pi \ln x - 3}{1.1x^2}. \tag{4.31}$$

Making the substitution $x = \mu w$ yields the desired result. □

**Lemma 4.16.** *For all $w \geq 300$,*

$$\begin{aligned} &2\left(\frac{\pi \ln w}{\lambda} + \frac{\pi \ln \lambda}{\lambda} - \frac{2}{\lambda} + \pi \ln w - 2\right) \\ &\quad < \frac{2\pi \ln w}{1.1\frac{\lambda}{2}} + \frac{2\pi \ln\left(\frac{\lambda}{2}\right)}{1.1\frac{\lambda}{2}} - \frac{6}{1.1\frac{\lambda}{2}} + \frac{\pi \ln w}{1.1} - \frac{3}{1.1} \\ &\qquad + \frac{\pi \ln w}{1.1(\lambda + 1)} + \frac{\pi \ln(\lambda + 1)}{1.1(\lambda + 1)} - \frac{3}{1.1(\lambda + 1)}. \end{aligned}$$

***Proof.*** For all $w \geq 300$,

$$\begin{aligned} &\pi\left(2\frac{\ln \lambda}{\lambda} - 2\frac{\ln \lambda/2}{1.1\lambda/2} - \frac{\ln(\lambda + 1)}{1.1(\lambda + 1)}\right) \\ &\qquad + \left(2\frac{3}{1.1\lambda/2} + \frac{3}{1.1} + \frac{3}{1.1(\lambda + 1)} - \frac{4}{\lambda} - 4\right) \\ &\quad < \left(\frac{2}{1.1\lambda/2} + \frac{1}{1.1} + \frac{1}{1.1(\lambda + 1)} - \frac{2}{\lambda} - 2\right)\pi \ln w. \end{aligned}$$

Simple algebraic manipulation gives the desired result. □

**Lemma 4.17.** *If* $w \geq 300$, *then*

$$\left(\frac{2\lambda}{\lambda w + \pi \ln(\lambda w) + 2} + \frac{2}{w + \pi \ln(w) + 2}\right) > \left(\frac{\lambda}{\lambda\frac{w}{2} + \pi \ln\left(\lambda\frac{w}{2}\right) - 3} + \frac{1}{w + \pi \ln(w) - 3} + \frac{\lambda + 1}{(\lambda + 1)w + \pi \ln((\lambda + 1)w) - 3}\right).$$

***Proof.*** By Lemma 4.14,

$$\begin{aligned}
&\frac{2\lambda}{\lambda w + \pi \ln(\lambda w) + 2} + \frac{2}{w + \pi \ln(w) + 2} \\
&\quad > 2\left(\frac{2}{w} - \frac{1}{w^2}\left(\frac{\pi \ln w}{\lambda} + \frac{\pi \ln(\lambda)}{\lambda} - \frac{2}{\lambda}\right) - \frac{1}{w^2}(\pi \ln w - 2)\right) \\
&\quad > \frac{4}{w} - \frac{1}{w^2}\left(\frac{2\pi \ln w}{1.1\frac{\lambda}{2}} + \frac{2\pi \ln\left(\frac{\lambda}{2}\right)}{1.1\frac{\lambda}{2}} - \frac{6}{1.1\frac{\lambda}{2}} + \frac{\pi \ln w}{1.1} - \frac{3}{1.1}\right. \\
&\qquad \left. + \frac{\pi \ln w}{1.1(\lambda + 1)} + \frac{\pi \ln(\lambda + 1)}{1.1(\lambda + 1)} - \frac{3}{1.1(\lambda + 1)}\right)
\end{aligned}$$

(by Lemma 4.16)

$$> \frac{\lambda}{\frac{\lambda w}{2} + \pi \ln\frac{\lambda w}{2} - 3} + \frac{1}{w + \pi \ln w - 3} + \frac{(1 + \lambda)}{(\lambda + 1)w + \pi \ln((\lambda + 1)w) - 3}$$

(by Lemma 4.15). □

**Proposition 4.18.** *If* $w \geq 300$, *then* $\frac{d}{dw}F(\lambda w, w) < 0$.

***Proof.*** Consider a standard double bubble enclosing volumes $\lambda w$ and $w$. Let $v_1, w_1$, be the volumes needed to complete the two outer caps of the double bubble which enclose volumes $\lambda w$ and $w$. Then,

$$\frac{dA}{dw}(\lambda w, w) = \lambda A'(\lambda w + v_1) + A'(w + w_1)\,. \tag{4.32}$$

The bound on $A'(x)$ given in Lemma 4.5 tells us that

$$2\lambda + 2\pi\left(\frac{\lambda}{\lambda\frac{w}{2} + \pi \ln\left(\lambda\frac{w}{2}\right) - 3}\right) > \lambda A'\left(\frac{\lambda w}{2}\right), \tag{4.33}$$

$$2 + 2\pi\left(\frac{1}{w + \pi \ln(w) - 3}\right) > A'(w), \text{ and} \tag{4.34}$$

$$2 + 2\pi\left(\frac{\lambda + 1}{(\lambda + 1)w + \pi \ln((\lambda + 1)w) - 3}\right) > A'((\lambda + 1)w)\,. \tag{4.35}$$

By Corollary 4.7,

$$\lambda A'(\lambda w + 3) + A'(w + 3) > \lambda\left(2 + \frac{2\pi}{\lambda w + \pi \ln(\lambda w) + 2}\right) + \left(2 + \frac{2\pi}{w + \pi \ln w + 2}\right). \tag{4.36}$$

Since $\lambda w$ and $w$ are greater than $300\lambda$, we can apply Lemma 4.13 to see that $v_1, w_1 < 3$. Hence,

$$\lambda A'(\lambda w + v_1) + A'(w + w_1) > \lambda A'(\lambda w + 3) + A'(w + 3)\,. \tag{4.37}$$

Therefore,

$$\lambda A'(\lambda w+v_1)+A'(w+w_1) > \lambda\left(2+\frac{2\pi}{\lambda w+\pi\ln\lambda w+2}\right)+\left(2+\frac{2\pi}{w+\pi\ln w+2}\right)\,. \tag{4.38}$$

By inequalities (4.38), (4.33), (4.34), (4.35), and Lemma 4.17, we can see for all $\lambda w, w > 300\lambda$,

$$2\lambda A'(\lambda w + v_1) + 2A'(w + w_1) > \lambda A'\left(\frac{\lambda w}{2}\right) + A'(w) + A'(\lambda w + w)\,. \tag{4.39}$$

Thus, we get the desired result,

$$2\frac{d}{dw}A(\lambda w, w) > \lambda A'\left(\frac{\lambda w}{2}\right) + A'(w) + A'(\lambda w + w)\,. \qquad \square \tag{4.40}$$

**Proposition 4.19.** *For $v \geq \lambda w$, $w \geq 150$,*

$$\frac{1}{\frac{v}{2}+\pi\ln\frac{v}{2}-1.041}+\frac{1}{v+w+\pi\ln(v+w)-1.041} > 2\frac{1}{v\pi\ln v-3}\,. \tag{4.41}$$

***Proof.*** Since $v \geq \lambda w$, $w \geq 150$,

$$\frac{v^2}{2} > 4(v+w)\left(\pi\ln\frac{v}{2}-1.041\right) \text{ and } \frac{v+w}{2} > \pi\ln(v+w). \tag{4.42}$$

Hence,

$$v^2(v+w) > (v+w)^2\frac{\pi\ln\frac{v}{2}-1.041}{\frac{1}{4}}+v^2\pi\ln(v+w)-1.041v^2-(v+w)^2\frac{\pi\ln v-3}{1.1}\,. \tag{4.43}$$

So,

$$\frac{2}{v}-\frac{\pi\ln\frac{v}{2}-1.041}{\left(\frac{v}{2}\right)^2}+\frac{1}{v+w}-\frac{\pi\ln(v+w)-1.041}{(v+w)^2} > 2\left(\frac{1}{v}-\frac{\pi\ln v-3}{1.1v^2}\right)\,. \tag{4.44}$$

Applying Lemmas 4.14 and 4.15 to the above equation yields,

$$\frac{1}{\frac{v}{2}+\pi\ln\frac{v}{2}-1.041}+\frac{1}{v+w+\pi\ln(v+w)-1.041} > 2\frac{1}{v+\pi\ln v-3} \tag{4.45}$$

as desired. $\square$

**Lemma 4.20.** *For any fixed $w \geq 150$ and $v \geq \lambda w$, $\frac{\partial F}{\partial v} > 0$.*

***Proof.*** Differentiating the Hutchings function with respect to $v$ yields

$$\frac{\partial F}{\partial v} = A'\left(\frac{v}{2}\right) + A'(v+w) - 2\frac{\partial}{\partial v}A(v,w) > A'\left(\frac{v}{2}\right) + A'(v+w) - 2A'(v)\,. \tag{4.46}$$

By Lemmas 4.6 and 4.5,

$$\frac{\partial F}{\partial v} > \frac{1}{\frac{v}{2}+\pi\ln\frac{v}{2}-1.041} + \frac{1}{v+w+\pi\ln(v+w)-1.041} - 2\frac{1}{v+\pi\ln v-3}\,. \tag{4.47}$$

The desired inequality follows from Proposition 4.19. □

**Theorem 4.21** (Hutchings function is positive for large volumes). *For all $v \le w$ such that $w > 300$ and $v > .85w$ (or indeed $v \ge \lambda w \approx .841w$), the Hutchings function $F(v,w) = 2A(\frac{v}{2}) + A(w) + A(v+w) - 2A(v,w)$ is positive.*

***Proof.*** Consider $(v,w) = (v_0, w_0)$, where $v_0/w_0 > .85 > \lambda$ and $w_0 > 300$. By Proposition 4.20 the derivative of $F$ with respect to its first argument is positive for the volume pairs under consideration, so $F(v_0, w_0) > F(\lambda w_0, w_0)$.

By Proposition 4.18 $F(\lambda w, w)$ decreases as $w$ increases and by Proposition 4.12,

$$F(\lambda w_0, w_0) > \lim_{w\to\infty} F(\lambda w, w) = 0\,.$$

Hence, $F(v_0, w_0) > 0$, as claimed. □

***Remark 4.22.*** The ratio $\lambda = e^2/4 - 1$ is sharp in the following sense: For $\psi < \lambda$, there exist arbitrarily large $v$, $w$ with $v/w = \psi$ such that the Hutchings function is negative. This is a result of Proposition 4.12.

## 5. The computer proof of the positivity of the Hutchings function in $\mathbf{S}^3$ and $\mathbf{H}^3$

Rigorously showing positivity of the Hutchings function is equivalent to showing that $g(v,w) = 2A(\frac{v}{2}) + A(w) + A(v+w)$ is strictly greater than $h(v,w) = 2A(v,w)$. The functions $g$ and $h$ have very similar properties in $\mathbf{S}^3$ and $\mathbf{H}^3$, but the proofs vary slightly because the areas of single bubbles and standard double bubbles are not increasing for all volumes in $\mathbf{S}^3$ and the $\mathbf{H}^3$ code has to efficiently calculate the curvatures of double bubbles.

The computer proof relies on the facts that $g$ is concave and $h$ is increasing on relevant domains (Propositions 2.6 and 2.7) in both spaces and that $g$ is increasing on all of $\mathbf{H}^3$. If $g$ and $h$ were each concave increasing functions of one variable, we could show that $g$ is bigger than $h$ on the interval $[v, v+b]$, by showing $g(v) > h(v+a)$ and $g(v+a) > h(v+b)$ (see Figure 4). The computational lemma (Lemma 5.1) extends this idea into two dimensions showing that $g > h$ on a polygonal domain in the $vw$-plane if the minimum value of $g$ on the vertex set is bigger than the maximum value of $h$.

Using a computer does introduce error, which must be accounted for. A computer uses approximations for $g$ and $h$, which we will call $g_{\text{comp}}$ and $h_{\text{comp}}$. However, if $g$ is underestimated and $h$ is overestimated then the computer test will show $g_{\text{comp}} > h_{\text{comp}}$ only if $g > h$.

The following lemma shows that checking a finite number of points can give a global inequality.

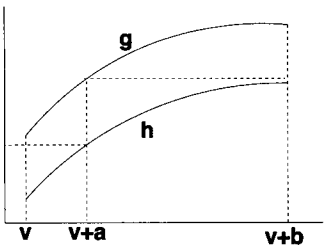

FIGURE 4 The steps to show that $g > h$ if both are concave increasing functions of one variable.

**Lemma 5.1.** *Given a polygonal domain $D$ with vertices identified by ordered pairs $(v_i, w_i)$, a concave function $g(v, w)$, and another function $h(v, w)$ with a maximum at $(v_0, w_0)$, if $\min(g(v_i, w_i)) > h(v_0, w_0)$ then $g > h$ on $D$.*

***Proof.*** Since $g$ is concave it has a minimum on $D$ at a vertex of the polygon. Thus, $\min(g(v_i, w_i))$ is a lower bound for $g$ on $D$ and $h(v_0, w_0)$ is an upper bound for $h$ on $D$. Hence, $g > h$ follows directly. □

**The computer proof in $S^3$.** In $S^3$, rectangular and triangular regions are considered. In $S^3$, there is additional computational complexity because $A(v)$ and $A(v, w)$ are not increasing for all volume pairs $(v, w)$. For rectangles where $h(v, w)$ is strictly increasing in a neighborhood of the rectangle, the area of the standard double bubble is over-approximated by using radii of the outer spherical caps corresponding to volumes $v_4 > v$ and $w_4 > w$ [see Figure 5(a)].

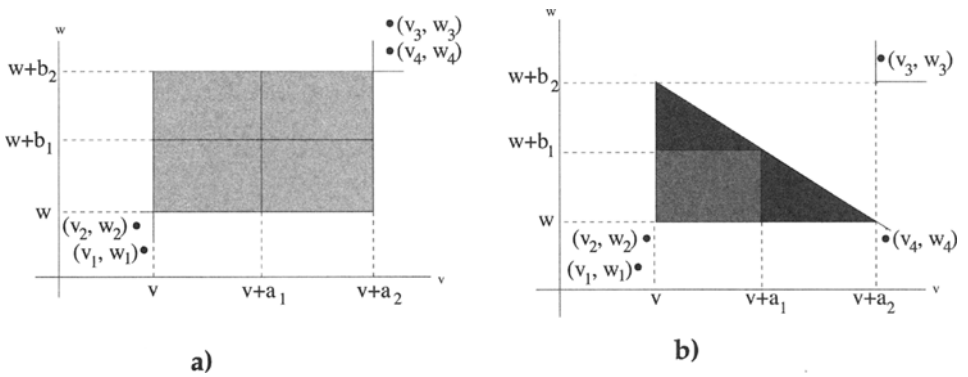

FIGURE 5 The steps needed to show that $g > h$ on (a) a rectangular region (b) a triangular region with A(v,w) increasing along the hypotenuse.

Let $g_1(v, w) = A\left(\frac{v}{2}\right) + A(w)$ and $g_2(v, w) = A(v + w)$. For the area of the single bubble each part of $g(v, w)$ is under-approximated. $A(\frac{v}{2})$ and $A(w)$ are always under-approximated by taking radii that correspond to spheres enclosing volumes less than $\frac{v}{2}$ and $w$. Evaluating $g_1$ at $(v_1, w_1)$ in Figure 5(a) and (b) gives a lower bound on $g_1(v, w)$ on the whole polygon. $A(v + w)$ is under-approximated by considering the minimum of the value of $A$ at a point to the lower left and a point to the upper right of the rectangle. This is the minimum of $g_2(v_2, w_2)$ and $g_2(v_3, w_3)$ in Figure 5(a) and (b).

If $g(v, w) \leq h(v+a_2, w+b_2)$ (where $v+a_2$ and $w+b_2$ correspond to Figure 5(a)), then the inequality is checked on the four rectangles with lower left corners of $(v, w)$, $(v+a_1, w)$, $(v, w+b_1)$ and $(v + a_1, w + b_1)$.

Next, we consider the entire region where numerical analysis is necessary (Figure 6). The

triangular domain is first broken into parts: The right triangle $(\bar{v}, \bar{w}) = (.1, .1), (.1, \frac{1}{3}), (\frac{1}{3}, \frac{1}{3})$ and the triangle $(\bar{v}, \bar{w}) = (.1, \frac{1}{3}), (\frac{1}{3}, \frac{1}{3})$ and $(.1, .45)$. The latter, upper triangle is difficult to deal with because $h$ is increasing up to the hypotenuse and decreasing above the hypotenuse. We can assure that we land exactly on this line by setting the two parameters $r_1$ and $r_3$ to be equal. Getting an over-approximation for area on this line just involves overestimating $r_1$. In addition, $A(\frac{1}{3}, \frac{1}{3})$ must be hard coded into the program as it is the global maximum. If we want to over-approximate $h(v, w)$ we move the point $(v, w)$ southeast along the line where $w = u$ to $(v_4, w_4)$ and use $h(v_4, w_4)$ as an over-approximation [see Figure 5(a)]. For $g$, we still just take the appropriate corners of the rectangle containing the triangle. If not, then we break the triangle into a rectangle and two smaller right triangles by connecting a point on the hypotenuse to the two legs of the triangle via perpendicular lines. The desired inequality is then shown to be true on the rectangle and the two smaller triangles. Similarly for the rectangle, if the desired inequality cannot be shown on the large rectangle, the rectangle is split into four smaller rectangles and the inequality is shown to hold true on them [see Figure 5(a)]. Both subdivisions repeat until the desired inequality can be shown on each subdivided rectangle or triangle. In the case where the upper right corner of a rectangle is on the line where $w = u$, we over-approximate $v, w$ using the same methods as the triangle. The lower triangle can be replaced by the rectangle containing it, which can then be subdivided into smaller rectangles by the argument above.

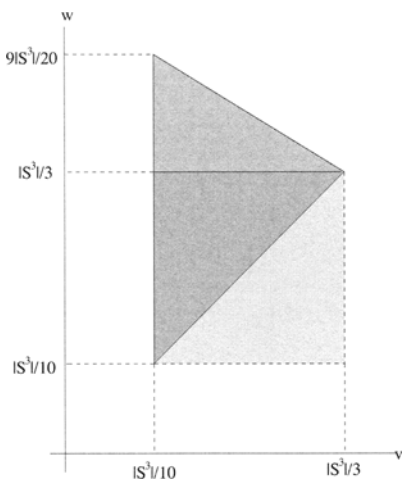

FIGURE 6 The triangular domain of the $(v, w)$ where numerical analysis is implemented.

Mathematica uses computer algebra (with infinite precision variables). When checking inequalities, it reports true, false, or null if it cannot tell for sure [15].

**The computer proof in $\mathbf{H^3}$.** In $\mathbf{H^3}$, rectangular regions that tile the area between two lines through the origin are considered (see Figure 7). The function $g$ is strictly increasing, so $g(v_0, w_0)$ is less than any value of $g(v, w)$ on a rectangular region with $v_0 \leq v$ and $w_0 \leq w$. We can assure that these two conditions hold if we take a guess at the curvature that we know to be too low (corresponding to a volume that is too high). Then, we increase the curvature (decreasing the volume) of the sphere by multiplying it by some constant. This process is done first with a relatively large constant until the curvature corresponds to volume that is too low; then the curvature is divided by the constant and the curvature is increased by a smaller constant until it corresponds to a volume that is less then the volume being approximated. Using this curvature for our surface area calculations under-approximates the surface area of single bubbles.

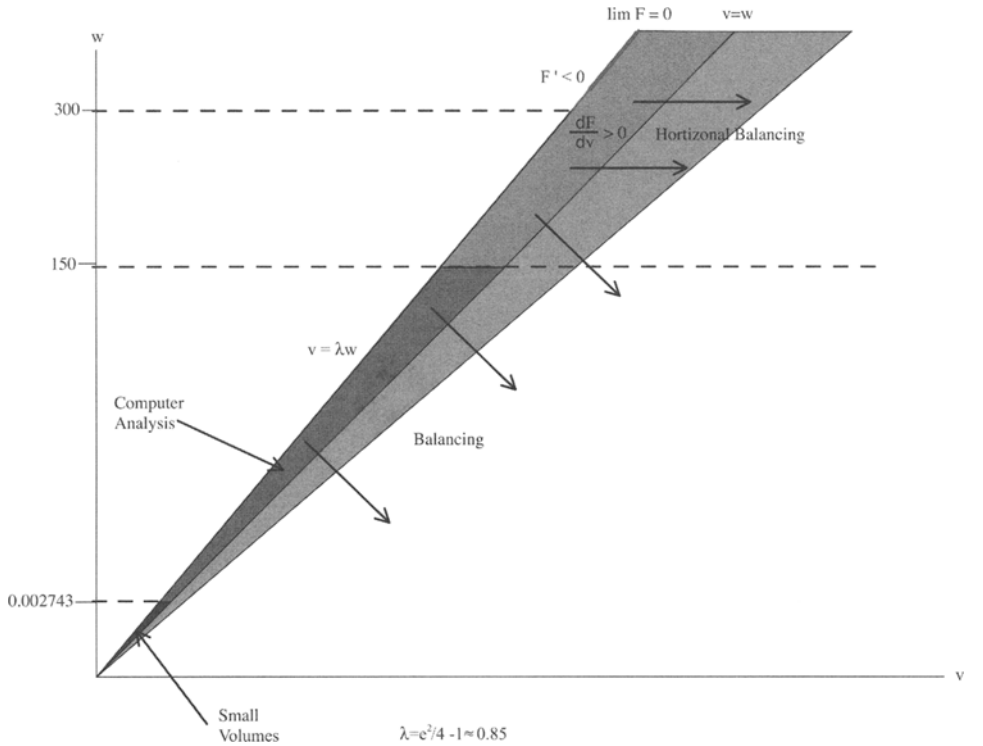

FIGURE 7 The basic steps of the proof that F is positive for $v \geq .85w$ and $w \geq .85v$ in $\mathbf{H}^3$.

For $A(v, w)$, the double bubble is completely determined by the mean curvatures of the outer caps. Thus, under-approximating the curvatures of these caps (by an analogous method to the single bubble case) corresponds to a double bubble with larger volumes and hence more surface area.

We use Mathematica's built-in *SetAccuracy* function, which assures accuracy on 25 binary digits right of the decimal point in our important computations. When we calculate curvature, we check that the calculated associated volume $VolSphere[k]$ is less than $v - 2^{-24}$, which guarantees that the associated volume is less that $v$. Hence, the associated area will be less than A. Finally, we subtract $2^{-24}$ from our calculated area to be sure that we have a lower bound.

We check that the calculated associated volumes $VolBubV[k1, k2]$ and $VolBubW[k1, k2]$ exceed v and w by $2^{-23} = 2 \cdot 2^{-24}$, because sometimes there are two numbers summed in the calculation. Hence, the associated area will be greater than A. We add $3 \cdot 2^{-24}$ to the calculated area to be sure.

When $w \geq 150$, the proof-function is restricted to showing that the Hutchings function is positive only on rectangles that include the line $v = .85w$.

***Remark 5.2.*** In $\mathbf{S}^3$, the proof-function determines the size of each polygon via a recursive algorithm. Both proof-functions (Claims 5.5 and 5.6) complete in under six hours each depending on computer speed. In $\mathbf{H}^3$, the proof-functions take about 150 hours to complete. The function is broken into pieces in order to maximize efficiency by choosing the rectangle size to be relatively large on a given region. Finally, the claim dealing with the ray $v = .85w$ completes in under three hours.

This section discusses the code in [4]. The computer proof in $\mathbf{S}^3$ uses two proof functions. The first is called ProofFunctionTriangle. The other is called ProofFunctionRectangle. The following claims can be proved by examining and running the code in the Appendix of [4]. The proof-functions returns a 1.

**Claim 5.3.** *The computed function A(v_, error_) returns a lower bound on the area of a sphere in* $\mathbf{S}^3$ *with given volume v.*

**Claim 5.4.** *The function A(v_, w_, VError_, WError_, changeToV_, changeToW_) gives an upper bound on A(v,w).*

**Claim 5.5.** *If ProofFunctionRectangle returns a 1 on a region, then the Hutchings Function is positive on this region.*

**Claim 5.6.** *If ProofFunctionTriangle returns a 1 on a region, then the Hutchings Function is positive on this region.*

**Implementation in** $\mathbf{H}^3$**.** The following claim can be proved by examining and running the code in the Appendix. The program stops if it finds a rectangle where $g \leq h$. Therefore, if the proof-function completes, the Hutchings function is positive on the region it was called on (Claim 5.7).

**Claim 5.7.** *If ArrayFillingProof completes then the Hutchings function is positive on the region it was called on.*

The following propositions consolidate the claims that the computer code runs showing the Hutchings function is positive on the desired domains. In order to decrease the number of computations needed, [4] uses a modified version of the code that checks only that the Hutchings function is positive on a small domain that includes the line $v = .85w$.

**Proposition 5.8.** *If an area-minimizing double bubble in* $\mathbf{S}^3$ *encloses volumes* $.1 \leq \bar{v} \leq \min\{\bar{w}, 1 - 2\bar{w}\}$, *then the Hutchings function* $F_{\mathbf{S}^3}(v, w) > 0$.

***Proof.*** This result can be verified by implementing ProofFunctionRectangle and ProofFunctionTriangle in the $\mathbf{S}^3$ section of [4]. □

**Proposition 5.9.** *If an area-minimizing double bubble in* $\mathbf{H}^3$ *encloses volumes* $v$, $w$ *such that* $.002743 \leq v \leq w \leq 150$ *and* $w \geq .85v$ *or such that* $w = .85v$ *and* $150 \leq w \leq 300$, *then the Hutchings function* $F_{\mathbf{H}^3}(v, w) > 0$.

***Proof.*** This result can be verified by implementing the ArrayFillingProof functions at the end of [4]. In the case where $w = .85v$, ArrayFillingProof is slightly modified so that the positivity of the Hutchings function is checked only on a neighborhood of $w = .85v$. □

## 6. Double bubbles in $\mathbf{S}^3$ and $\mathbf{H}^3$

Theorems 6.3 and 6.4 provide our main results on double bubbles in $\mathbf{S}^3$ and $\mathbf{H}^3$. They depend on Propositions 6.1 and 6.2 of Cotton and Freeman [7], after Hutchings et al., which reduce the proofs to our connectivity results of Sections 3–5 via the Hutchings Function.

**Proposition 6.1** ([7, Proposition 7.3]). *An area-minimizing double bubble in* $\mathbf{S}^3$ *for which both enclosed regions and the exterior are connected must be standard.*

**Proposition 6.2** ([7, Proposition 7.7]). *An area-minimizing double bubble in* $\mathbf{H}^3$ *for which both enclosed regions are connected must be standard.*

**Theorem 6.3** (Area-minimizing double bubbles in $\mathbf{S}^3$). *An area-minimizing double bubble in* $\mathbf{S}^3$ *is standard if the volume of each of the three regions is larger than 10% of the total volume of* $\mathbf{S}^3$.

***Proof.*** By Proposition 6.1, it suffices to show that all regions are connected. By Lemma 2.9, we know that the region of volume $v$ is connected whenever $v > 2w$ or $v > 2u$ [Figure 8(a)]. This reduces the problem to showing that the region of volume $v$ is connected on the pentagonal domain of Figure 8(e) defined by the points: $(\bar{v}, \bar{w}, \bar{u}) = (.1, .1, .8), (.1, .8, .1), (.2, .7, .1), (.5, .25, .25)$, and $(.2, .1, .7)$. By Proposition 2.3, it suffices to show that the Hutchings function $F(v, w)$ is positive on this domain. When $.1 \leq \bar{v} \leq \bar{w}$ and $\bar{v} \leq 1 - 2\bar{w}$, computer analysis [Proposition 5.8, see Figure 8(b)] tells us that the Hutchings function $F(v, w)$ is positive. In particular, for $\bar{v} \leq \frac{1}{3}$, $F(v, v)$ is positive. When $\frac{1}{3} \geq \bar{v} > \bar{w}$ and $v \leq 2w$, by S-balancing [Proposition 2.8, see Figure 8(c)] $F(v, w) > 0$ on the quadrilateral domain with endpoints: $(\bar{v}, \bar{w}, \bar{u}) = (.1, .1, .8), (\frac{1}{3}, \frac{1}{3}, \frac{1}{3}), (\frac{4}{9}, \frac{2}{9}, \frac{1}{3})$, and $(.2, .1, .7)$. Thus $F(v, w) > 0$ on the pentagonal domain gained by S-balancing in addition to the region where the computer analysis was done. Hence, by permutation [Proposition 2.10, see Figure 8(d)], $F(v, w) > 0$ on the pentagonal domain with endpoints: $(\bar{v}, \bar{w}, \bar{u}) = (.2, .7, .1), (\frac{4}{9}, \frac{1}{3}, \frac{2}{9}), (\frac{1}{3}, \frac{1}{3}, \frac{1}{3}), (.1, .45, .45)$, and $(.1, .8, .1)$. In particular, if $\bar{v} \leq .45$, $F(v, v) > 0$. By S-balancing [Proposition 2.8, see Figure 8(e)] $F(v, w) > 0$ whenever $\bar{w} \leq \bar{v} \leq 2\bar{w}$. Thus, $F(v, w) > 0$ on the pentagonal domain $(\bar{v}, \bar{w}, \bar{u}) = (.1, .1, .8), (.1, .8, .1), (.2, .7, .1), (.5, .25, .25)$, and $(.2, .1, .7)$. □

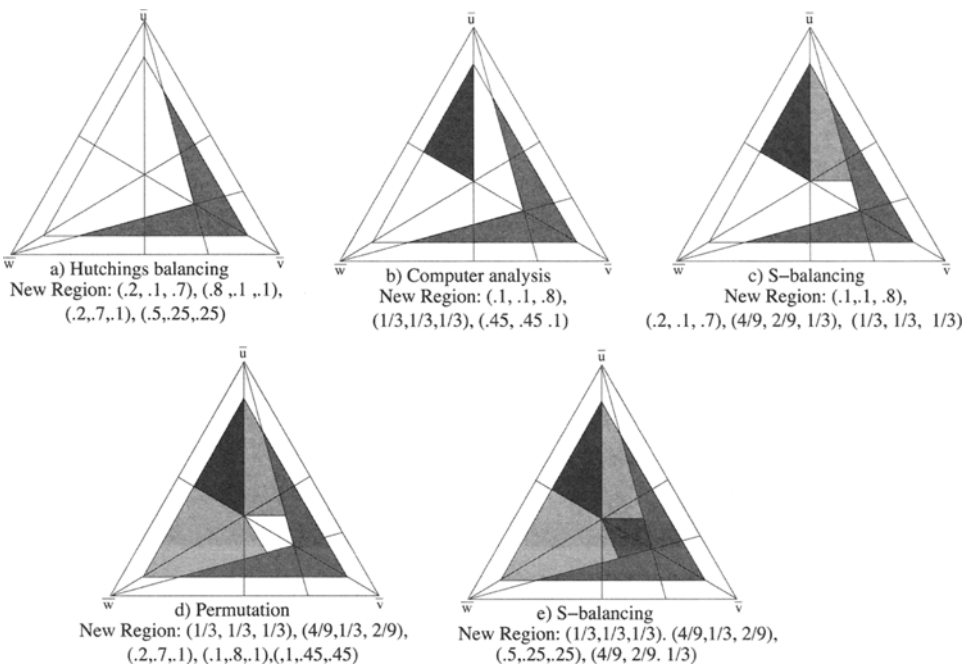

FIGURE 8 An illustration of the steps taken to cover the whole domain of volumes on $\mathbf{S}^3$.

**Theorem 6.4** (Area-minimizing double bubbles in $\mathbf{H}^3$). *An area-minimizing double bubble in* $\mathbf{H}^3$ *is standard if the volume of the smaller region is at least* 85% *of the volume of the larger region.*

***Proof.*** By Proposition 6.2 it suffices to show that the two enclosed regions are connected. By Proposition 2.3, it suffices to show that the Hutchings function $F(v, w)$ is positive for $(.85)^{-1}w \geq v \geq .85w$ (see Figure 7). Computer analysis (Proposition 5.9) shows that when $.002743 \leq v \leq w \leq 150$ and $v \geq .85w$, the Hutchings function $F(v, w)$ is positive. It also shows that the Hutchings function is positive along the line segment $v = .85w$, $w \in [150, 300]$. Since the partial derivative of the Hutchings function with respect to v is positive for $w \geq 150$ (Lemma 4.20), $F(v, w) > 0$ for $w \in [150, 300]$. Asymptotic analysis (Theorems 3.5 and 4.21) shows that $F(v, w) > 0$ when $v \leq w < .002743$ or $v/.85 \geq w \geq 300$. In particular, $F(v, v) > 0$ is positive. When $(.85)^{-1}w \geq v \geq w$, Proposition 2.8 shows that $F(v, w) > 0$. □

***Remark 6.5.*** In hyperbolic quotient spaces, Theorem 6.4 and [1, Remark 4.4] prove that the standard double bubble is area minimizing for some small volume pairs where the smaller volume is at least 85 percent that of the larger.

**Future work.** It follows from Theorem 6.4 and balancing (Lemma 2.9, Proposition 2.8) that the largest region in $\mathbf{H}^3$ is always connected. Connectivity of the largest region is the key hypothesis for the even more general instability argument used in $\mathbf{R}^4$ [13, Section 8]; future work might produce an analog of this result for $\mathbf{H}^3$.

## Acknowledgments

We would like to thank Colin Adams for posing this problem and for his insightful questions and helpful conversations. We would also like to thank David Futer, Matt Kudzin, and Pat McDonald for helpful conversations. Finally, we would like to thank Frank Morgan for his direction and advice.

This research is the joint work of SMALL undergraduate research Geometry Group from '01, '02 and '03, and was completed by Neil Hoffman (Geometry Group '03) in his undergraduate thesis work [9]. We thank the National Science Foundation, Williams College, and the organizers of the SMALL REU for helping to make this research possible.

# A Scholia-based Document Model for Commons-based Peer Production

Joseph Corneli and Aaron Krowne

**Abstract:** Commons-based peer production is a term that describes authorship of shared information resources. In this article we examine the technical aspects of writing-in-common. We begin with a simple model: that of text and commentary. This scholia-based model emphasizes *ownership of speech* and *freedom of speech*. We then consider what happens when the *freedom to create derivative versions* is added to the mix. The resulting model proves to be quite sophisticated, and flexible enough to describe many different commons-based peer production systems. We provide an overview of our implementation of this model, and suggest some ideas for subsequent work. We conclude by discussing the implications of our model for distributed authorship and writing.

## INTRODUCTION

The simplest model of a document is a list of characters; a string, file, or buffer. This model is not diachronic; a diachronic model keeps track of editing operations, or summarizes them as a sequence of differences between document versions.

Many texts have features which can not be modeled adequately without still more information: markup or metadata. Compilations, hypertext, and collaboratively written documents are examples. In this essay, we advance the idea that it can be useful to treat such documents and document ensembles as collections of *scholia*.

### The Digital Library and the Document

For our purposes, the document and the library are essentially the same. In other words, the traditional library-document dichotomy can be viewed as a smooth spectrum, which we consider as a whole. Towards one end of the spectrum, the number of authors decreases and the topics under discussion become more integrated, and the information artifacts look more document-like. Towards the other end, the number of authors grows and the semantic gaps

M. Halbert (Ed.): *Free Culture and the Digital Library Symposium Proceedings*. Atlanta, Georgia: MetaScholar Initiative at Emory University, 2005. pp. 241-254.

This work is covered by the Creative Commons Attribution-NonCommercial-NoDerivs 2.5 License.

between topics increase, and the information artifacts become more library-like. To be clear, when we wish to refer to elements of a given information artifact in a generic way, we will call them *articles*. We will use the term "scholium" to describe an article that is about another article. While a given article need not be about another article in general, our view is that it is about *something*, or perhaps about many things. An article that does not express these relationships explicitly is a degenerate scholium.

**Scholia**

According to Webster,[1] a *scholium* (pluralized *scholia*) is,

1. A marginal annotation; an explanatory remark or comment; specifically, an explanatory comment on the text of a classic author by an early grammarian;

2. A remark or observation subjoined to a demonstration or a train of reasoning.

The Talmud is an excellent example of a document that is comprised of scholia. This document is a collection of interconnected commentaries and reflections on Jewish law (the *Torah*), composed by generations of Jewish religious scholars. There is an obvious and oftnoted comparison between the internet and the Talmud: we readily see ancient scholia-based documents as primitive hypertext. However, a deeper comparison is not simply technological but psycho-social.[2] There are similarities between our experiences of "culturally comprehensive" documents, whether secular or religious in nature. Of course, if you subscribe to the McLuhan view of media ("the medium is the message"), you would expect to see similarities (Federman 2004; McLuhan 1964).

Scholia also appear in the writings of mathematical scientists (*e.g.* Euclid, Galileo, and Newton) or philosophers writing in a similar style (*e.g.* Spinoza). Today, mathematicians typically call peripheral observations (frequently, of secondary importance) "corollaries" or "remarks." Mathematicians also mark up parts of their texts as "axioms," "definitions," "propositions," "theorems," "lemmas," or "proofs." Markup, in general, can be thought of as scholia-based, *i.e.*, as commentary that instructs the typesetter or the reader to treat a given piece of content in a certain way.

## Free culture and the scholia-based document

This paper, and the system it describes, are a response to certain concerns that face us when we work with and think about shared information resources. These concerns have to do with the issues of *intersubjectivity*, *ownership*, and *freedom*. Content in a shared document is typically of non-trivial intersubjective importance. However, it is more than likely that different parties will have some different ideas about the information that is presented in a given text (it is no coincidence that the root of *intersubjective* is *subjective*)!

Free content (*i.e.* free as in freedom, or *libre* content) is one way to nurture difference. Free content can be modified and redistributed (and, in particular, *forked*) without permission or apology. Nevertheless, free content typically manifests aspects of a common resource as well as an open access resource; while anyone can do essentially whatever they wish with the content offline, in its online life, the content is managed in a socially-mediated way. In particular, rights to *in situ* modification tend to be strictly controlled. The details differ from ownership model to ownership model (*e.g.*, PlanetMath has article owners and access control lists, software projects like Emacs have a limited number of developers with commit privileges, members of the Wikipedia community enforce rules about what kinds of content are allowed, and so forth). In these instances and generally, unwillingness to cooperate comes at a cost of valuable support from the community, which must be balanced against the limitations the community imposes on the individual.

By finding new ways to support freedom of speech within CBPP documents, we embrace subjectivity as a way to enhance the content of an intersubjectively valued corpus. In the context of "hackable" media and maintenance protocols, the semantics with which scholia are handled can be improved upon indefinitely on a user-by-user basis and a resource-wide basis. This is free culture in action.

## Hyperreal Texts

Our interest in scholia-based documents largely derives from an interest in helping assemble a human-friendly, AI-enriched mathematics learning and communication interface. The immediate goal is a system in which text and code are both well-supported, as two sides of the same coin. Qualitatively, we want want to be able to represent and work with complex ontological

relationships between entities that are encoded in the system. The system should be useful for both humans and programs—balance along the human/artificial axis is as important toward this end as balance along the freedom/ownership axis or the intersubjective/subjective axis. In short, we find it natural to use a scholia-based platform as the foundation of our *Hyperreal Dictionary of Mathematics* project.[3] Applications in other areas of intellectual inquiry (including digital libraries), as well as in business, government, and day-to-day life also seem to hold great promise.

## Inspiration

We have already seen glimpses of the ideology informing this paper (in particular, we've touched on free software, commons-based peer production, the Talmud, and mathematics). We'll come to more of this later on. Here, we would like to describe certain key technological inspirations. These should serve to illustrate the naturality of a scholiabased document model, as well as to contextualize our implementation of the model. Usenet, Slashdot, the World Wide Web and WikiWikiWeb are all inspirations. In the first two, the most obvious type of scholium is the *followup*. In the latter two, it is the *link*.

PlanetMath[4] uses several types of scholia. Discussion fora are attached to pretty much every "substantial" object in the system; there are auto-generated invocation links between articles; and attachment relationships can be asserted to apply to between objects. Objects can themselves be distinguished as being one of several different types and belonging to one of a number of different subject categories. Also, and most importantly for the current discussion, PlanetMath employs an explicit article ownership model.

Emacs text properties provide a facility for unlimited markup of strings, buffers, and files.[5] However, text properties are hierarchical (treelike), whereas we are looking for something web-like. Of course, locally, text properties are great (and, indeed, we use them in our implementation).

The semantic web project is exploring ways in which to make metadata about web pages available to computers with reasoning capabilities.[6] Our scholia-based documents are small "semantic webs" with a particular flavor, though it may be more appropriate to use the older and more generic term "semantic network" (Quillian 1968) to describe them. As a data structure, a scholia-

based document is a network with arbitrary text (and metadata) on its nodes and arbitrary annotations on the connections between nodes. Graphically, this closely resembles the notion of a *concept map* (Novak 1998), albeit with significant text content attached to each node.

Semantic networks and concept maps are just two of the many different strategies for knowledge representation. Cyc[7] and KM[8] are two other systems we've studied. Our goal is a system with similar expressive power, but which is more human-friendly (with *reasoning* capabilities to come eventually).

The first author's earlier hypertext experiments were heavily inspired by LISP, and the results ended up resembling Gopher (Karger 2000). The current system is meant to be much richer, but it is still LISP-inspired, particularly in terms of support for self-modification. Indeed, one of the key inspirations for the current system are the text-based "game" environments (MUDs,[9] etc.), in which people are able to "hack" the text-based virtual worlds that they are interacting in and with, in real time.[10] Scholia can include actionable features, and with appropriate support, contributing authors can modify the medium in which the scholia reside, not just its content.

**Survey**

The scholium-based document is not a new idea. Here, we are referring not to classical works, but to Ted Nelson's project and document model entitled *Xanadu*, which is described in his book *Literary Machines* (Nelson 1990), originally published in 1982. His development strategy was quite different from the one taken here, however—in particular, while he and his cohorts were focused on developing powerful server-side technology, we focus on implementing user-ware with a simple p2p extension. Importantly, while at least some of Nelson's ideas have been implemented and released under a free software license, the code didn't compile for us.[11] A biography of sorts together with a history of the Xanadu project has been published in *Wired*.[12] Nelson is admired by FSF General Counsel, Eben Moglen, for "identifying the predicament of information ownership in the digital age" (Williams 2002).

One rather important difference between Nelson's vision (as expressed in *Literary Machines*) and the present one is that he deprioritizes artificial intelligence in favor of human intelligence. As remarked above, actionable features and artificial intelligence

occupy an important place in the scholium system. Our situation with regard to artificial intelligence is similar to the one described by Minsky in *The Society of Mind* (Minsky 1985). The connection between ideas and agents is not so dissimilar; only the translation to actionable form is missing to make an idea into an agent. Meaning clusters translate to complex agencies. As time goes by, we expect to find actionable and non-actionable features paralleling one another along some dimensions, intertwining along some, and diverging on others.

"Superimposed information" is a subject of current research in the field of digital libraries.[13] Note that while this model is *locally* similar to the scholia-based document model, this branch of research focuses on one superimposed layer. This makes a certain amount of sense for traditional libraries, which hold a specific, administratively-controlled collection of information. The superimposed information model emphasizes making this primary artifact more useful via value-added "attachments" (annotations and so forth). However, for us, neither library nor document is static, and annotations are an integral part of both. Thus, scholia-based documents are as much "community" as they are "collection."

We find it compelling that, in the context of a digital library, marginal conversations within a text provide a chance for readers to interact with primary authors and with each other, and to become primary authors themselves, all at once. While marginalia are considered to be *vandalism* in physical library books, in a digital library, there is no reason to fear them—they can easily be hidden away. The scholia-based document model reflects the standard postmodern pun which says that writing on a text or subject (*i.e.* criticism, discourse) is writing *on* the text (making ones mark). We expect meaning to accumulate in the "margins" of texts, and for meaning complexes to grow by stitching documents together along their margins.

## IMPLEMENTATION OVERVIEW

In this section we give a tour of our implementation of the scholium system. The critical elements of the system are described in general terms here. Details, including code (and literate markup of the code) may be found at (Corneli 2004).

## Articles

The foundation of the scholium system is a catalog of articles (list or hash table). Adding or updating the reference for an article to the catalog is the fundamental operation in the system. This operation stores

- the article's name;
- its text or a pointer to its text;
- a record of what it is about—nothing if it is degenerate, otherwise, some article(s) or passage(s) of articles in the collection;
- the designation of a type (link, followup, forum, action to take if a certain event happens at the parent, etc.);
- and bookkeeping information to keep track of ownership information and editing history.

In Figure 1, we illustrate the conceptual model of the scholium system with a hypothetical content instance. Shown are the key entities of *people*, *articles*, and *references*.

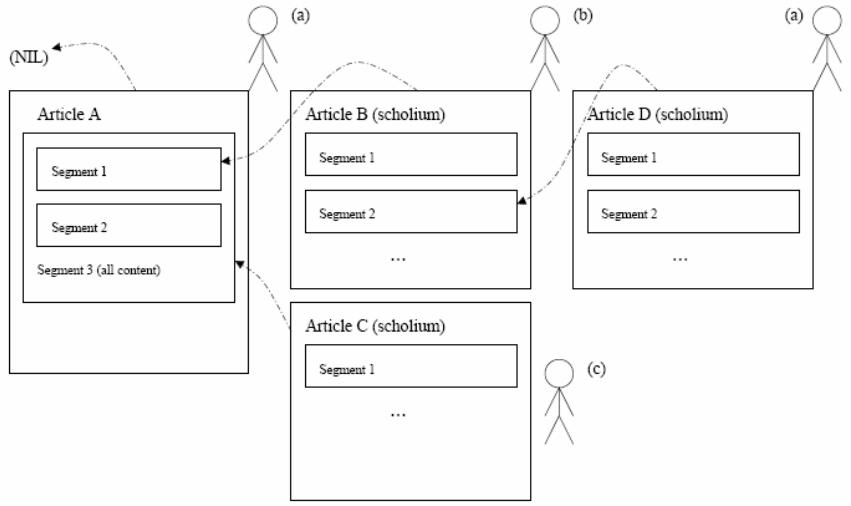

Figure 1: The key elements of the scholium system, for a hypothetical small document/library. There are three people (a, b, and c), and four articles (A, B, C, and D). All articles are scholia (i.e. refer to another article), except A. The contents of each article have been broken into "segments" for clarity. Links are shown as dashed arrows from articles to article segments.

## Environment

The current prototype system runs under GNU Emacs. We try to conform to the Emacs Way to the greatest extent possible. Typically, scholia are written about files and buffers, and are displayed alongside them. The default display uses color to associate displayed scholia with regions that are being commented on, but delimiters can be used for this purpose as well (for the benefit of those working without fontlock). Color can also be used to distinguish between different types of scholia (*e.g.* comments by different authors).

Our ability to render articles is limited to things Emacs can display: plain text, code, and pictures all work, but special proprietary formats are not supported in this implementation, nor do we have support for making scholia about specific pieces of a rendered diagram, for example.

The user can navigate the display in various ways, e.g., by scrolling between marked-up regions of the main article, or finding the region(s) associated with a given scholium, or the scholia associated with a given region. Additional browsing methods are described below.

## Displaying Scholia

When an article is displayed, the system finds attached scholia and displays them too. Selective displays are possible (*e.g.* just show all the *links* attached to a given article). Finding scholia in the catalog requires search; sometimes we can limit the search to make it faster (this will be described further below). In Figure 2, we show a number of ways in which the underlying content from Figure 1 can be displayed.

## Adding to the library

We support various convenient ways to add articles. Different kinds of articles need different treatment. For example, the content of a buffer is lost if the buffer is killed, so a backup of the buffer's contents should be made immediately. In addition to specifying the article's text and stating what (if anything) it is about, one can specify the article's type. We provide built-in functions for creating scholia about the current buffer, and for creating scholia about mixed collections of other articles and passages.

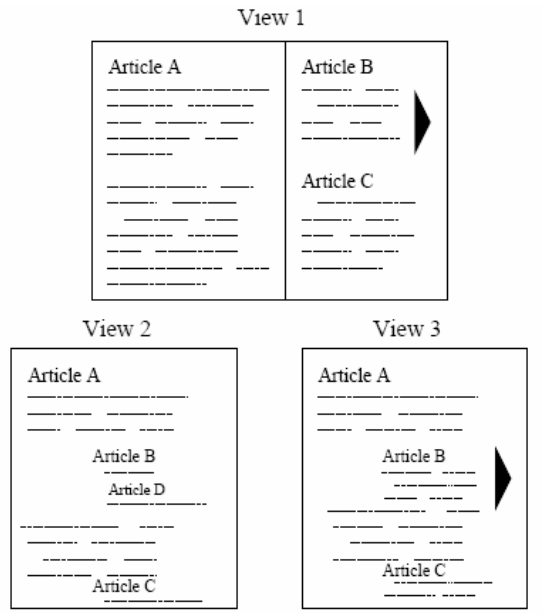

Figure 2: Different possible views of the articles from Figure 1. Three views are shown. View 1 is a two-pane style, with attached scholia on the right and the main article on the left. View 2 includes only title and linkage information for attached scholia, unfolding recursively to a user-specified depth. View 3 is a single-frame view, with one level of attached scholia inclusion (deeper levels are indicated with an arrow).

## Browsing

We provide several different browsing mechanisms. Simple local navigation features (scrolling etc.) were mentioned above. “Following” a scholium to make it into the new current article is supported. Browsing by catalog (*i.e.*, by list) is supported; we use a generic menu mechanism that make it easy to select different collections of articles matching different criteria, and perform various actions on them. Finally, web-browser-like history-based navigation is provided.

## Editing, deleting, saving, restoring

Articles are versioned and entire document versions or, alternatively, a collection of patches sufficient to move between versions, is maintained for each article. When articles change, it is typically necessary to propagate data to attached scholia in order to maintain coherence of references. Propagated changes need not be accepted, in which case the attachment relationship is fixed at the previous version.

Similarly, permission is typically requested whenever a portion of an article that has been *transcluded* changes. ("Transclusion" is Nelson's term for "included by reference"; both transclusion and inclusion of pieces of other articles are supported.)

Changes that take place to articles outside of the system (*e.g.* moving a file from the shell) are of course nearly impossible to deal with. However, scholia can be saved in explicit, invariant forms. (CVS is natively supported).[14] Saved articles can be read back in selectively.

Currently, name conflicts pose a bit of a problem; if every scholium has a unique name, then the problem goes away. In general, we can approximate a solution by asking the user to uniquify names when conflicts are encountered.

### Namespaces

Another solution to the problem of name conflicts is provided by namespaces. For example, if article *A* has type "sublibrary" and we read in a scholium of type "member of sublibrary *A*," then we don't have to worry about name conflicts with articles not in sublibrary *A*. Namespaces can be used to make search convenient. For example, we can store all assertions of type *Z* in a given namespace; then if we are building a display that only relates to objects of type *Z*. In other words, we need only search one namespace instead of the whole library.

## DISTRIBUTED AUTHORSHIP

Distributed authorship is actually very easy using this system. Each contributing author posts her or his contributions to the document at their own chosen location. Then the other authors download the articles stored in all of the locations they want to use. (All authors don't necessarily need to have all of the articles.) In the case of document revision, changed versions are simply posted, and other authors learn of the changes whenever they sync.

### Derivative versions

In general, the author may be the only person with permission to create modified versions, but we can also distribute this permission over a wider group of people. As we've already mentioned, derivative versions can be put together using two principles, inclusion and transclusion. Inclusion tends to reduce search but increase storage.

Here we illustrate *tracking* of derivative versions with a scenario. Suppose that a series of definitions was quoted in a textbook-style entry. The author of the textbook might receive a question from a reader and then adjust one of these definitions to include more expository text. If the original author was tracking derivative versions, the new expository text could be added as a scholium attached directly to the original, or the original could be modified.

These sorts of exchanges should still be possible even if one of the agents is working outside of the scholia-based system. In order to make *bi-directional updating* work in this case, both content-sharing parties need to be able to read a stream of diffs generated by edits taking place in another system and decide how to incorporate the modifications.

These issues should be of interest to anyone maintaining a collaborative digital library; information-sharing between such entities typically needs to support content that can change on both ends of the pipeline.

## FUTURE WORK

Some ideas for explorations to undertake with the scholium system and related concepts follow. Note that some of these could be considered feasibility or proof-of-utility experiments:

- Import a wiki and build a wiki-like interface to the scholium system;
- Use the scholium system to write a synchronous or asynchronous multiplayer game;
- Use the scholium system to maintain a text-based forum or set of fora, as found on PlanetMath or Slashdot;
- Implement a Slashdot-like scoring system for quality control;
- Use the scholium system to manage an evolving codebase (*i.e.*, take advantage of the functionality which subsumes a system like CVS);
- Use the scholium system to manage TODO lists;
- Port the GNU Collaborative Dictionary of English (GCIDE) to Emacs and give instant access to definitions as scholia;
- Implement code to make an index or do autolinking as you type;
- Port WordNet15 to the scholium system and use the system to collaboratively improve the database;

- Implement semi-automated content sharing between two collaborative digital libraries, for instance, PlanetMath, and Wikipedia.

This list should give some idea of the range of capabilities the scholium system, in theory, encompasses. Long term investigations under conditions of fairly wide uptake would shed light on broader social implications of the system. We imagine that social institutions—from peer review to popular science, and from online shopping to participatory government—would tend to be transformed by widespread use of these systems. In fact, some of this social transformation is already apparent—in specialized implementations of the scholia concept (*e.g.* weblogs, wikis, online forums, PlanetMath). Currently we can only speculate as to how the general system outlined here would interact with these trends.

One thing we can say at this point is that the model seems to provide a useful basis from which to explore the design and implications of social contracts in online communities. We hope future work will take up this issue.

## CONCLUSION

In this article, we have described a scholia-based document model and outlined an implementation of a system that supports this model. We have discussed some ramifications of scholia-based documents and libraries. We have have also shown how the model can be used to facilitate powerful collaboration dynamics in a wide array of scenarios and social settings—by fostering and managing alternative perspectives, encouraging responsible maintainership, and enabling readers to routinely make useful contributions.

The scholia-based document model corresponds to a culture with empowering conceptualizations of freedom and ownership. Accordingly, this paper has been a description of a model as well as something of a social manifesto. We hope to see the ideas presented here take off, as we and others work to push the limits of the model.

### Acknowledgments

Thanks to Ray Puzio for helpful comments and encouragement as the scholium system developed. Thanks also to Thien-Thi Nguyen and Sacha Chua for their comments on free software and hypertext, including comments on an earlier prototype of the system by the first author.

# THE DOUBLE BUBBLE PROBLEM ON THE FLAT TWO-TORUS

JOSEPH CORNELI, PAUL HOLT, GEORGE LEE, NICHOLAS LEGER,
ERIC SCHOENFELD, AND BENJAMIN STEINHURST

Abstract. We characterize the perimeter-minimizing double bubbles on all flat two-tori and, as corollaries, on the flat infinite cylinder and the flat infinite strip with free boundary. Specifically, we show that there are five distinct types of minimizers on flat two-tori, depending on the areas to be enclosed.

## 1. Introduction

Our Main Theorem 6.1 shows that on any flat two-torus, the least-perimeter way to enclose and separate two prescribed areas is a double bubble of one of the five types shown in Figure 1: the standard double bubble, the band lens, a standard chain, the double band, or the standard hexagon tiling. Figure 2 gives "phase portraits," computational plots of the minimizing type for given areas, for four different tori. (Section 8 describes the creation of these phase portraits, using formulas for the perimeter and area of the five minimizers derived in Section 7.)

The strategy of the proof is to separate all candidates into five classes, as described in Proposition 4.6. Proposition 4.6 says that a minimizer must either be the double band or (possibly after relabelling the two interior regions and the exterior) belong to one of four other topological classes: Section 5.1 deals with contractible double bubbles; Section 5.2 deals with double bubbles whose components taken together wrap around the torus, and whose complement is not contractible; Section 5.3 deals with double bubbles with one band adjacent to a contractible set of components; and Section 5.4 deals with double bubbles for which both enclosed regions and the exterior region are contractible.

The last of these topological classes (with both regions and the exterior contractible) we refer to as "tilings" because the three regions taken together lift to a tiling of the plane. Despite escaping our initial conjectures, this class turned out to be one of the most interesting. Whereas the nontiling types tie only for prescribed areas in the transitions between phases (Figure 2), the hexagon tiling and the double band provide distinct minimizers over an open set of areas (Figure 2(b)) — the first example of such a phenomenon in double bubble history. Another candidate tiling, the octagon square, with one region consisting of two four-sided components (Figure 23), was the last candidate to be eliminated (Proposition 5.4.22).

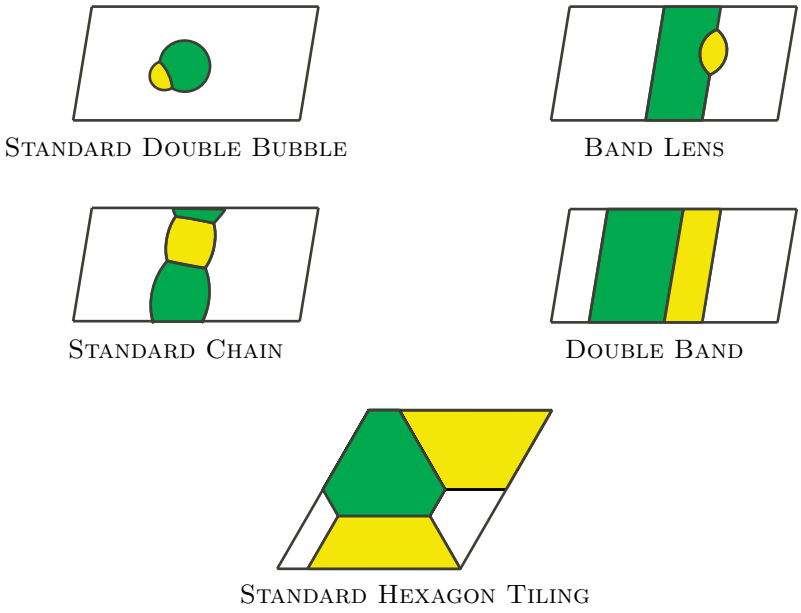

FIGURE 1. There are five types of perimeter-minimizing double bubbles on a flat two-torus. The standard hexagon tiling occurs only on the hexagonal torus.

We also consider the double bubble problem on the flat infinite cylinder, which is simpler because there are no candidate tilings. Corollary 6.3 provides a complete characterization of the minimizers in this space as a trivial consequence of the torus result, and the cylinder result is used in Corollary 6.5 to characterize all minimizers on the flat infinite strip with free boundary.

The torus and cylinder lack the useful symmetries used in other spaces to establish connectedness of the exterior and bounds on the number of components. Luckily, the recent work of Wichiramala [MW] on the triple bubble problem in the plane gave us a very useful component bound (Proposition 3.7).

**History and recent developments.** The double bubble problem is a generalization of the isoperimetric problem. Given a geometric space, the latter seeks the least-area way to enclose a single volume. (A solution to the isoperimetric problem on the flat two-torus can be found in [HHM].) The double bubble problem seeks the least-area way to enclose and separate two volumes. In recent years, this problem has been solved in a number of spaces, including $\mathbf{R}^2$ [F], $\mathbf{S}^2$ [Ma2], and still more recently $\mathbf{R}^3$ [HMRR] and $\mathbf{R}^4$ [RHLS]. In these cases the minimizers are all standard double bubbles, in contrast to the multiplicity of types on the torus. Some of the major contributions were due to undergraduates affiliated with Williams College and the Williams "SMALL" REU program. Underlying all of these results is geometric measure theory as developed by Federer, Fleming, Almgren, and others. For a more complete discussion of the history of the double bubble problem as well as many related problems on films, foams, and other efficient surfaces, see [M1].

The triple bubble problem in the plane has recently been solved by Wichiramala [W]. On the other hand, even the single bubble problem remains unsolved on a torus

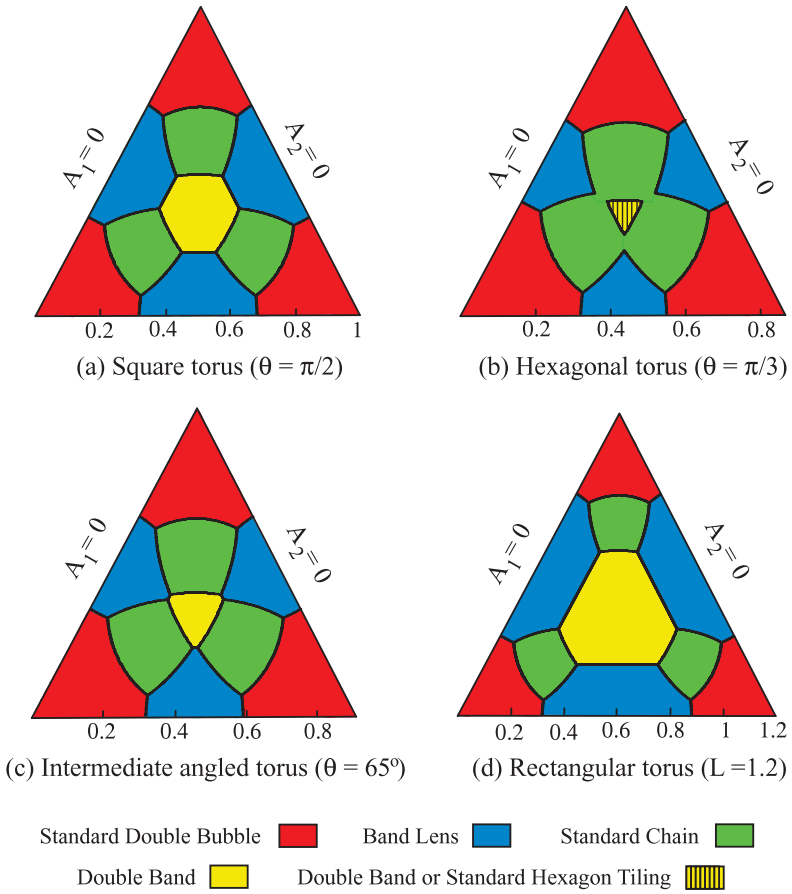

FIGURE 2. These phase portraits show which type of double bubble is minimizing given prescribed area pairs $(A_1, A_2)$ on four specific flat tori. Each torus for (a)–(c) has a rhombic fundamental domain with interior angle $\theta$; the torus for (d) has a rectangular fundamental domain with side lengths 1 and $L = 1.2$.

of revolution. We have contributed to a paper that gives experimental evidence on the solutions to the double bubble problem in a cubic flat three-torus [CCWB], another space where the single bubble problem is still open.

## 2. Definitions

This section contains definitions for, among other things, the classes of potential minimizers mentioned above.

### 2.1. **Tori and the cylinder.**

**Definition 1.** A *flat two-dimensional torus* can be represented by a planar parallelogram with opposite sides identified. Throughout the paper the torus is normalized so that each shortest closed geodesic has unit length.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Remark* 2.1.1. The parallelogram can be chosen such that one shortest side is a shortest closed geodesic and no interior angle is less than sixty degrees. Then the area of the parallelogram, and hence the area of the torus, is at least $\sqrt{3}/2$ with equality precisely for the hexagonal torus (see Definition 2).

**Definition 2.** The *hexagonal torus* can be represented either by a regular hexagon with opposite sides identified with the same orientation, or by a 60-degree rhombus with opposite sides identified with the same orientation.

**Definition 3.** We say that each shortest closed geodesic lies along a *short direction* of the torus. On certain nonhexagonal tori (those that can be represented by a parallelogram with four sides of unit length), there are two short directions; on the hexagonal torus, there are three.

**Definition 4.** The *flat infinite cylinder* can be represented as the surface contained between two identified infinite parallel lines in the plane, where each segment perpendicular to and connecting the lines is a closed geodesic. The *flat infinite strip with free boundary* is the surface between the same two lines, except that the lines are not identified; portions of the lines may be included in the boundary of a double bubble without contributing to the perimeter of the double bubble.

2.2. **Topological definitions.**

**Definition 5.** A *double bubble* on a smooth Riemannian surface consists of two disjoint regions (i.e., nonempty open sets) bounded by piecewise smooth curves, such that the exterior of these regions has nonzero area. The boundary of the double bubble divides the surface into three regions: the two regions belonging to the double bubble, which we call the *enclosed* regions, and the complement of the closure of the double bubble, which we call the *exterior* region. Any of the three regions may have multiple components.

*Remark* 2.2.1. On the torus, by relabelling which of the three regions in a double bubble is the exterior, we can obtain two other double bubbles with the same boundary. On the infinite cylinder, the exterior region has infinite area.

**Definition 6.** A *tiling* is a double bubble on the torus for which each component, including each component of the exterior, is contractible, such as the standard hexagon tiling of Figure 1. It is called a tiling because the two enclosed regions plus the exterior region lift to a tiling of the plane.

**Definition 7.** An *octagon-square tiling* is a tiling in which one of the three regions consists of two curvilinear quadrilaterals, and each of the other two regions consists of one curvilinear octagon (see Figure 23).

**Definition 8.** A *band* is a noncontractible annulus.

**Definition 9.** A *swath* is a set of contractible components with noncontractible complement and whose union has noncontractible and connected closure, such as the standard chain of Figure 1.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Definition 10.** A *chain*, such as the standard chain of Figure 1 or the chain of Figure 3, is a minimal swath — that is, a swath without a proper subset of components that themselves form a swath. Note that every swath contains at least one chain and that every chain is itself a swath.

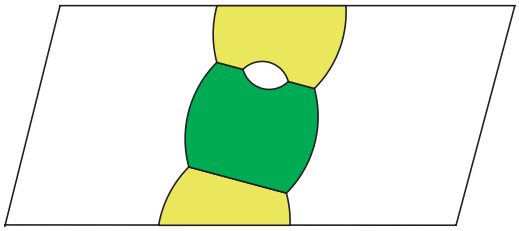

FIGURE 3. The two shaded six-sided components form a *chain*, even though there is a curvilinear digon embedded between them. The two shaded components plus the curvilinear digon do not form a chain, because the swath they form is not minimal.

**Definition 11.** Two closed curves lie in the same *homology class*, or have the same homology, if they can be smoothly deformed into each other along the surface of the torus. Given two different oriented directions of the torus (i.e., directions of closed geodesics on the torus), the homology class of a closed curve is given by an ordered pair $(p, q)$, where the curve wraps around the torus $p$ times in the first direction and $q$ times in the other direction. (The ordered pair is well defined up to negating both $p$ and $q$.) We will refer to the homology of a band or chain $K$, by which we mean the homology of any noncontractible component of the boundary of $\overline{K}$.

2.3. **Geometric definitions.**

**Definition 12.** The *standard double bubble* is comprised of three circular arcs meeting in threes at 120°, such that the curvature of the arc separating the contractible components is the difference of the curvatures of the outer caps. For prescribed areas, there is a standard double bubble in the Euclidean plane, unique up to congruence [M1, Proposition 14.1]; it may or may not fit on the torus.

**Definition 13.** The *double band* consists of two adjacent bands, bounded by three shortest closed geodesics.

**Definition 14.** A *symmetric chain* is a chain that is symmetric about a closed geodesic with the same homology as the chain.

**Definition 15.** A *standard chain* is a symmetric chain enclosing two four-sided components whose boundary is comprised of six circular arcs that satisfy the regularity conditions in Proposition 3.1. That is, the arcs meet in threes at four common vertices at 120° such that the curvature of each arc separating the two components in the chain is the difference of the curvatures of the outer arcs (see Figure 1). The *axis-length* of a standard chain is the length of the geodesic with the same homology as the chain.

*Remark* 2.3.1. Our parameterization of the standard chain (Section 7.2, see Remark 7.2.3) proves existence of some family of standard chains. Furthermore, there exists

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

graphical evidence that the only chains that are minimizing are those with the same homology as a shortest closed geodesic (Remark 5.2.16).

We believe the standard chain is also unique up to isometries of the torus for given areas and homology class. Indeed, a parametric plot in *Mathematica* (see Figure 4) suggests that different standard chains with the same homology enclose different area pairs.

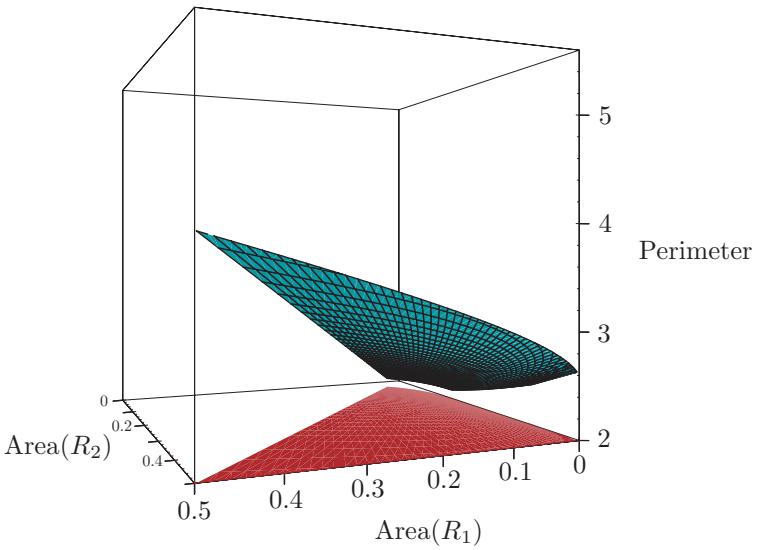

FIGURE 4. This parametric plot from *Mathematica* of perimeter as a function of areas for standard chains with axis-length 1. The plot has no folds in it and contains only one sheet, suggesting uniqueness for prescribed area pairs $A_1 \leq A_2$.

**Definition 16.** A *lens* is a pair of congruent circular arcs meeting at two vertices at 120°.

*Remark* 2.3.2. It is easily shown that if the distance between the two vertices is less than or equal to 1, then the lens can be embedded on any torus with its axis along any short direction.

**Definition 17.** A *band lens* consists of a band and a lens, such that the boundary curves meet in threes at two vertices at 120°, as in Figure 1.

*Remark* 2.3.3. By Lemma 5.3.6, a minimizing band lens on the torus has the same homology as a shortest closed geodesic (that is, the closed geodesic bordering the band has length one). It is easy to see that when a minimizing band lens enclosing two given areas exists, it is essentially unique for those areas (up to isometries of the torus).

**Definition 18.** A *hexagon tiling* is a tiling in which every component of the double bubble and exterior is a hexagon with interior angles of 120°.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Definition 19.** The *standard hexagon tiling* is a hexagon tiling on the hexagonal torus, which partitions the torus into three hexagonal regions, whose boundary edges lie parallel to the three short directions of the torus. By Corollary 7.4.3 and Lemma 7.4.4, the standard hexagon tiling exists and is unique for a particular range of area pairs.

## 3. Existence, regularity, and basic properties

This section provides existence and regularity of perimeter-minimizing double bubbles (Proposition 3.1), a bound on the number of components for minimizers (Proposition 3.7), and an easy but important perimeter bound (Proposition 3.8).

**Proposition 3.1** (Existence and Regularity Theorem [M2, 2.3 and 2.4])**.** *In a smooth Riemannian surface $S$ with compact quotient by its isometry group, for any two areas $A_1$ and $A_2$ (whose sum is less than the area of $S$), there exists a least-perimeter enclosure of the two areas. This enclosure consists of finitely many smooth constant-curvature curves meeting in threes at* 120° *angles. No boundary curve separates components of the same region, and all curves separating a specific pair of the three regions have the same (signed) curvature. Moreover, the enclosure satisfies the cocycle condition: the sum of the signed curvatures around any closed path is zero.*

*Remark* 3.2. In particular, given any minimizing double bubble on the torus, each of the three regions contains finitely many components.

*Remark* 3.3. It follows that in a minimizing double bubble on the torus, the union of the closures of any two regions is connected. Otherwise, two disjoint pieces of this union can be translated to be made tangent, forming a new minimizer that violates regularity, a contradiction. In particular, each component (in either of the two enclosed regions or the exterior region) is adjacent to components of both other regions.

*Remark* 3.4. It also follows that alternating sides of a component must border different regions. Hence, any contractible component in a minimizing double bubble or its exterior has an even number of sides.

*Remark* 3.5. A perimeter-minimizing double bubble is in *equilibrium*: under any smooth variation that preserves areas, the derivative of perimeter with respect to time is initially zero. (Here by "variation" we mean a perturbation of the double bubble over time.) For a piecewise smooth double bubble, being in equilibrium is equivalent to having boundary curves that satisfy the given curvature conditions, satisfy the cocycle condition, and meet in threes at 120° (see, for instance, [HMRR], Lemma 3.1).

*Remark* 3.6. The curvature and cocycle conditions imply the existence of a well-defined *pressure* for each region with the following property: the difference between the pressures of any two regions in an equilibrium double bubble is the curvature of the separating arcs between those regions, signed so that a curve separating two regions bows into the region of lower pressure. (For instance, we could set the pressure of the exterior region to equal zero and set the pressure of each enclosed region to equal the curvature of the interface separating that region from the exterior.) A least-pressure nonpolygonal contractible component must have more than six sides;

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

and a highest-pressure nonpolygonal contractible component must have fewer than six sides.

**Proposition 3.7** (Wichiramala component bound [MW, Proposition 3.1])**.** *Unless all three regions have equal pressure, each region of highest pressure in a perimeter-minimizing double bubble in the flat two-torus has at most two contractible components.*

*Proof.* The proof in [MW], which we sketch here, uses variations that shrink or expand a high-pressure nonpolygonal component at a constant rate along its boundary. If there are at least three such components in some region, then some nontrivial linear combination of the corresponding "shrink and expand" variations will preserve the areas of each region to first order. Each of the three variations will contribute a negative term to the second variation of the combined variation, so that the new variation has negative second variation (i.e., negative second derivative of perimeter with respect to time). In this case, we call the double bubble "unstable," and no such double bubble is perimeter minimizing. The topology of the torus does not affect this proof. □

**Proposition 3.8** (Perimeter bound)**.** *The perimeter of a perimeter-minimizing double bubble in the flat two-torus is at most* 3*.*

*Proof.* A double band of perimeter three can enclose any pair of prescribed areas, so no minimizer can have greater perimeter. □

## 4. Topological classification of minimizers

This section proves two important propositions. Proposition 4.5 says that if the three regions in a perimeter-minimizing double bubble all have equal pressure, then it is a hexagon tiling or the double band. Proposition 4.6 is the backbone for the proof of our Main Theorem 6.1. It shows that any minimizing double bubble must be a tiling, a contractible double bubble, a swath, a single band adjacent to a contractible set of components, or the double band. Section 5 will treat in turn each of these topological classes.

**Lemma 4.1.** *A noncontractible component $C$ in a minimizing double bubble must either be a band or have contractible complement.*

*Proof.* If every component of the boundary of $C$ is contractible, then the complement of $C$ is contractible.

Otherwise, some component $\sigma$ of the boundary of $C$ is noncontractible, and any other noncontractible component of the boundary of $C$ has the same homology as $\sigma$. Thus, $C$ must be a band with that homology, except possibly with some collection of contractible components in its interior. But such contractible components never exist in a minimizing double bubble (Remark 3.3), so $C$ must indeed be a band. □

**Lemma 4.2.** *Consider a fundamental domain of the torus, a parallelogram with sides* $1, L$ *and interior angle* $\theta \in [\pi/3, \pi/2]$*. Suppose that a chain or band is part of a minimizing double bubble and has homology* $(p, q)$*, defined with respect to two directions along the sides of the parallelogram. Then* $|p|, |q| \leq 1$*.*

*Proof.* Each band or chain has least two disjoint, noncontractible boundary curves. If $|p| \geq 2$ or $|q| \geq 2$, then the length of each of these boundary curves is at least

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

$\sqrt{3}$, and the total perimeter is at least $2\sqrt{3}$. By the perimeter bound (Proposition 3.8), the double bubble cannot be a minimizer. □

**Lemma 4.3.** *A perimeter-minimizing double bubble on the torus, together with its exterior, has at most three disjoint bands or chains. If there are three, then the double bubble must be the double band.*

*Proof.* Each band or chain has at least two noncontractible boundary curves, and each such boundary curve borders at most two bands or chains. Hence, if there are $n$ bands and chains, then there will be at least $n$ such noncontractible boundary curves, each with length at least one. Then by Proposition 3.8, $n \leq 3$. If $n = 3$, then the boundary must consist entirely of three parallel closed geodesics, each of length one. In this case, the double bubble must be the double band. □

**Lemma 4.4.** *In a perimeter-minimizing double bubble with three equal pressures, every component in the double bubble plus exterior is either a vertex-free band or a hexagon.*

*Proof.* Consider any component in the double bubble plus exterior, and let $\mathcal{C}$ be the boundary of this component.

Because the double bubble has three equal pressures, any vertex-free component of $\mathcal{C}$ is linear and thus must be a closed geodesic.

Suppose that a component of $\mathcal{C}$ has at least one vertex. Then it has positive total turning angle, whereas any noncontractible closed curve has total turning angle 0. Hence, if a component of $\mathcal{C}$ has at least one vertex, then it is contractible. Also, it consists of straight edges meeting at interior angles measuring $2\pi/3$ — precisely the configuration of a hexagon.

Therefore, every component of $\mathcal{C}$ is a closed geodesic or a contractible hexagon, and the desired result follows easily. □

**Proposition 4.5.** *A perimeter-minimizing double bubble with three equal pressures is either a hexagon tiling or the double band.*

*Proof.* By Lemma 4.4, each component in the double bubble plus exterior is a vertex-free band or a hexagon. If every component is a hexagon, then the double bubble is a hexagon tiling. If every component is a band, then because there are at least three components, by Lemma 4.3 the double bubble is a double band. Finally, the double bubble cannot contain both bands and hexagons, because no band can be adjacent to a hexagon without violating regularity (Proposition 3.1). □

**Proposition 4.6.** *A minimizing double bubble on the torus must be a contractible double bubble, a tiling, a swath, a band adjacent to a set of components such that the closure of their union is contractible, or the double band (after perhaps relabelling the two regions and the exterior).*

*Proof.* We will categorize the minimizing double bubble by the number and type of noncontractible components in the double bubble plus its exterior. By Lemma 4.1 any noncontractible component must either be a band or have contractible complement. If the double bubble plus its exterior has in any region (say, in the exterior) a component with contractible complement, then the double bubble is contractible. Thus, for our remaining cases we can assume that all noncontractible components are bands.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

If the double bubble plus its exterior has no bands, then every component (of the double bubble plus its exterior) is contractible, and by definition the double bubble is a tiling.

If the double bubble plus its exterior has exactly one band, say in the exterior, then the double bubble consists of contractible components. But the closure of the union of this set of components is noncontractible, because it shares a noncontractible boundary curve with the band. Furthermore, any minimizing double bubble is connected (Remark 3.3). Then by definition the double bubble is a swath.

If the double bubble plus its exterior has exactly two bands (say, with at least one band in the exterior), then consider the set $C$ of the contractible components — that is, the set of components different from the bands. Suppose some subset of these components has noncontractible and connected closure. Then $C$ contains a swath, and therefore a chain. Now the double bubble plus its exterior has two bands and at least one chain, so by Lemma 4.3 it is not perimeter minimizing. Therefore, $C$ must be a contractible set of components. The two bands must then be adjacent to each other, and hence lie in different regions. Then the double bubble contains exactly one band, together with a subset of $C$ — that is, the double bubble is a band adjacent to contractible set of components.

If the double bubble plus its exterior has three or more bands, then by Lemma 4.3, the double bubble must be the double band. □

## 5. The four classes with contractible components

By Proposition 4.6, upon relabelling, every minimizing double bubble on the torus must be a contractible double bubble, a tiling, a swath, a band adjacent to a set of components whose union is contractible, or the double band. While the double band describes a specific geometric configuration, each of the remaining possibilities is merely a topological class of configurations. This section identifies the potential minimizer in each of these four remaining topological classes: the standard double bubble among contractible double bubbles (Proposition 5.1.2), a standard chain among swaths (Proposition 5.2.15), the band lens among double bubbles with a single band adjacent to a contractible set of components (Proposition 5.3.5), and the standard hexagon tiling among tilings (Proposition 5.4.23).

5.1. **Contractible double bubbles.** Proposition 5.1.2 uses the result from $\mathbf{R}^2$ that perimeter-minimizing double bubbles are standard [F], to show that the only potential minimizer among contractible double bubbles is the standard double bubble.

**Proposition 5.1.1.** *The perimeter of any planar standard double bubble is greater than $\pi$ times its diameter: $P > \pi D$.*

*Proof.* We obtain a formula for $P/D$ as a function $f(\theta)$, where $\theta \in [0, \pi/3)$ is the angle between the interior arc of the standard double bubble and the chord that connects the endpoints of the arc (see Figure 5). Then we show $f(\theta) > \pi$ for the entire domain $0 < \theta < \pi/3$. (A separate computation easily verifies the inequality $P > \pi D$ when $\theta = 0$.)

Let $r_1, r_2, c_1, c_2$ be the radii and centers of the longer and shorter exterior arcs of the standard double bubble, respectively. Then the diameter is the sum of $r_1$, $r_2$, and the distance between $c_1$ and $c_2$:

$$D = r_1 + r_2 + r_1 \cos(\pi/3 - \theta) + r_2 \cos(\pi/3 + \theta).$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

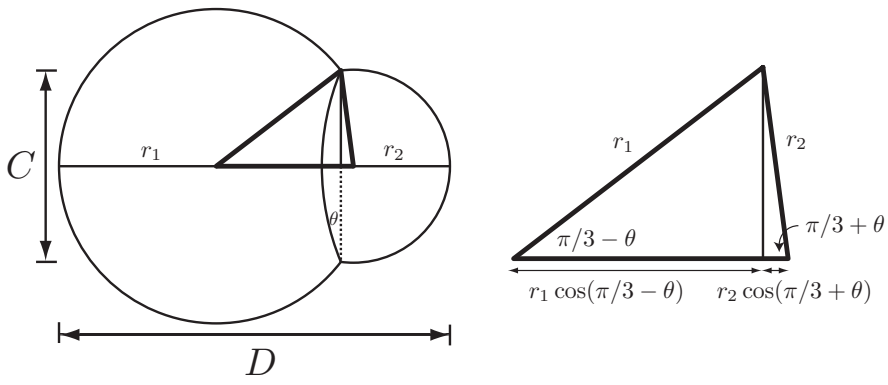

FIGURE 5. The perimeter of the standard double bubble is greater than $\pi$ times its diameter.

Applying the formula for radii (see (7.3)), we obtain an expression that can be solved for $C$, the length of the chord connecting the two vertices:

$$D = C\left(\frac{1+\cos(\pi/3-\theta)}{2\sin(2\pi/3+\theta)} + \frac{1+\cos(\pi/3+\theta)}{2\sin(2\pi/3-\theta)}\right).$$

Substituting for $C$ in the formula for perimeter (see (7.2)) yields after some simplification the desired function in $\theta$:

$$f(\theta) = P/D = \frac{8\pi\sin\theta\cos\theta + 3\sqrt{3}\theta}{6\sin\theta\cos\theta + 3\sin\theta}.$$

Now, showing $f(\theta) > \pi$ is equivalent to showing

$$8\pi\sin\theta\cos\theta + 3\sqrt{3}\theta > \pi(6\sin\theta\cos\theta + 3\sin\theta).$$

Moving the terms to the left-hand side and using the identity $\sin(2\theta) = 2\sin\theta\cos\theta$ gives the equivalent inequality

$$g(\theta) = \pi\sin(2\theta) + 3\sqrt{3}\theta - 3\pi\sin\theta > 0$$

with

$$g''(\theta) = -4\pi\sin(2\theta) + 3\pi\sin\theta = \pi\sin\theta(-8\cos\theta + 3).$$

For $\theta$ in $(0, \pi/3)$, $\sin\theta > 0$ while $\cos\theta > \cos(\pi/3) > 3/8$. Therefore, $g''(\theta)$ is strictly negative. Because $g(\theta)$ equals 0 at both endpoints of this interval, it must be positive along the interior, as desired. □

**Proposition 5.1.2** (Suggested by Masters [Ma1])**.** *The standard double bubble is the only contractible double bubble that may be a minimizer.*

*Proof.* Assume that there is a perimeter-minimizing contractible double bubble $\Sigma$ enclosing areas $A_1$ and $A_2$ that is not the standard double bubble. By [F], the unique perimeter-minimizing solution in $\mathbf{R}^2$ for the same prescribed areas is a standard double bubble, $\Theta$. By the perimeter bound (Proposition 3.8), $\Sigma$ has perimeter at most three. Since $\Theta$ has less perimeter than $\Sigma$, the perimeter $P$ of $\Theta$ satisfies $P < 3$.

By Proposition 5.1.1, the diameter $D$ of $\Theta$ satisfies $D < P/\pi < 1$. Hence, it fits on the torus with its axis of symmetry in any direction (Figure 6). Therefore, $\Theta$ is

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

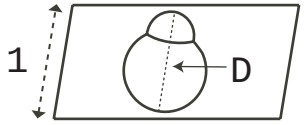

FIGURE 6. A standard double bubble with minimizing perimeter has diameter $D \leq 1$ and hence fits on the torus.

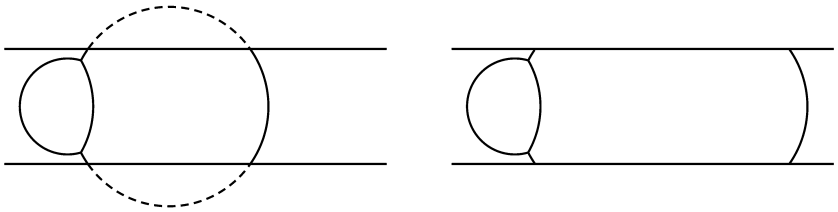

FIGURE 7. If a standard double bubble does not fit on the cylinder, we can easily construct a double bubble with even less perimeter.

a double bubble on the torus enclosing areas $A_1$ and $A_2$ with less perimeter than $\Sigma$, a contradiction. □

*Remark* 5.1.3. There is an easier argument on the infinite cylinder: when $\Theta$ does not fit with its diameter parallel to the sides of the cylinder, we can modify its boundary to create a new double bubble with less perimeter than $\Theta$ and enclosing the same areas, contradicting the assumption that there is a nonstandard contractible minimizer (see Figure 7).

5.2. **Swaths of contractible components.** Recall that by Definition 9 a swath is a set of contractible components with noncontractible and connected closure, and with noncontractible complement, such as the standard chain of Figure 1. This section shows that minimizing chains are standard chains (Definition 15), exactly as in Figure 1. Lemma 5.2.11 shows that minimizing swaths must be chains consisting of curvilinear quadrilateral components. Lemma 5.2.13 shows that asymmetric chains satisfying regularity cannot be minimizers since they have perimeter greater than three. Finally, Proposition 5.2.15 shows that minimizing symmetric chains are standard.

*Remark* 5.2.1. In this section, we often speak about contractible four-sided components as if they sat in the plane rather than a torus, because it is easier to talk about lines, reflections, and circles in the plane. (Lines can wrap around a torus infinitely many times, reflections across lines on a torus do not always exist, and circles on a torus may overlap themselves.)

**Lemma 5.2.2** ([W, Lemma 5.31])**.** *Given a contractible four-sided component in a regularity-satisfying double bubble or its exterior, the vertices of the component lie on a circle or a line. They lie clockwise on the circle or line in the same or opposite order as they appear clockwise on the boundary of the four-sided component.*

*Proof.* [W, Lemma 5.31] actually considers four-sided components in regularity-satisfying triple bubbles in the plane. However, the proof looks at each contractible

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

four-sided component in isolation from the rest of the triple bubble, using only the facts that each side has constant curvature, that the sides do not intersect each other, and that the sides meet at angles of $2\pi/3$. Thus, the proof also applies to contractible four-sided components of double bubbles in the torus.

[W, Lemma 5.31] is also slightly more limited than our result, not proving that if the vertices of the component lie on a line, then they do so in the same order that they appear on the boundary of the component. However, it does offer a proof of the analogous fact about the vertices when they lie on a circle, and this proof can be easily modified to give our complete result. □

**Lemma 5.2.3.** *Given a contractible four-sided component with vertices $A, B, C, D$ in a regularity-satisfying double bubble or its exterior, $AB = CD$ unless sides $AB$ and $CD$ of the component lie on the same circle or line.*

*Proof.* By Lemma 5.2.2, vertices $A, B, C, D$ lie on a circle or line $\omega$. Suppose that sides $AB$ and $CD$ do not lie on the same circle or line. By regularity in double bubbles, sides $AB$ and $CD$ have constant curvature and lie on some circles or lines $\omega_1$ and $\omega_2$, respectively. Also by regularity, sides $AB$ and $CD$ have the same curvature, and they meet side $BC$ at equal angles (namely, $2\pi/3$). Hence, $\omega_1$ and $\omega_2$ are reflections of each other across the perpendicular bisector of $\overline{BC}$. Thus, $\omega_1 \cap \omega = \{A, B\}$ and $\omega_2 \cap \omega = \{C, D\}$ are reflections of each other across the perpendicular bisector of $\overline{BC}$ as well, implying that $AB = CD$. □

**Lemma 5.2.4.** *Given a contractible four-sided component in a regularity-satisfying double bubble or its exterior, the vertices of the component do not lie on a line.*

*Proof.* Let the vertices of the component be $A, B, C, D$ in that order along the boundary of the component. Suppose, for sake of contradiction, that the vertices lie on a line $\ell$. By Lemma 5.2.2, $A, B, C, D$ lie in that order along $\ell$ — without loss of generality, $\ell$ is horizontal with $A$ at the left and $D$ at the right. Because $BC \neq DA$, Lemma 5.2.3 implies that sides $DA$ and $BC$ of the component lie on the same circle or line. The only circle or line that contains all four vertices $A, B, C, D$ is $\ell$, so that sides $DA$ and $BC$ of the component are linear and lie along $\ell$. However, this is impossible because then sides $DA$ and $BC$ would overlap, a contradiction. □

**Lemma 5.2.5** (Compare [W, proof of Lemma 5.3])**.** *Given a contractible four-sided component in a regularity-satisfying double bubble or its exterior, the vertices of the component form a nondegenerate isosceles trapezoid. The vertices appear clockwise on this trapezoid in the same order as they appear clockwise on the boundary of the component. If the trapezoid is not a rectangle, then the two boundary curves subtended by the parallel sides of the trapezoid lie on a circle circumscribing the polygonal quadrilateral.*

*Proof.* By Lemmas 5.2.2 and 5.2.4, the polygonal quadrilateral $ABCD$ formed by the vertices of the component is inscribed in some circle $\omega$; the vertices appear on the quadrilateral in the same order that they appear on the circle (although perhaps with different orientation).

By regularity, curvilinear sides $AB, BC, CD, DA$ cannot all lie along $\omega$. Without loss of generality, assume that sides $AB$ and $CD$ do not lie on the same circle. By Lemma 5.2.3, we have $AB = CD$. Hence, because quadrilateral $ABCD$ is inscribed in a circle, it must be an isosceles trapezoid with $\overline{BC} \parallel \overline{DA}$.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

If sides $BC$ and $DA$ of the curvilinear component do not lie on the same circle, then by the same analysis we have $BC = DA$, so that quadrilateral $ABCD$ is a rectangle (Figure 8(a)). Also, if trapezoid $ABCD$ is not a rectangle, say because $BC \neq DA$, then sides $BC$ and $DA$ of the curvilinear component *do* lie on the same circle (Figure 8(b)).

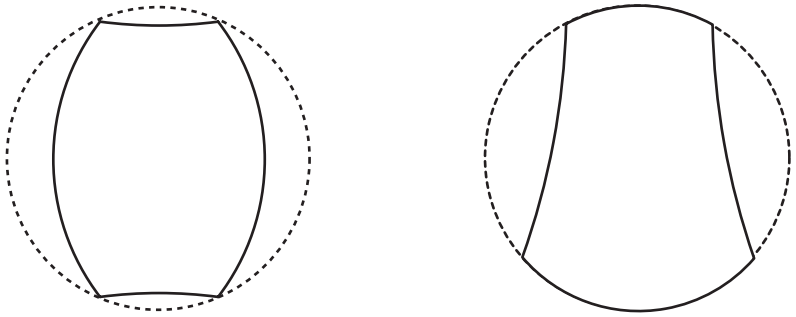

FIGURE 8. The vertices of any four-sided component lie on a circle. Either (a) the vertices form a rectangle, or (b) two opposite sides of the component lie along the same circle.

Finally, it remains to show that the vertices appear clockwise on the boundary of the component in the same order as they appear clockwise on the trapezoid. Because the vertices form a trapezoid (say, with $\overline{BC} \parallel \overline{DA}$), the four-sided component is symmetric about the perpendicular bisector $m$ of sides $BC$, $DA$ of the component. It follows easily that neither side $AB$ nor side $CD$ intersects $m$, implying the desired fact about the order of the vertices. □

**Lemma 5.2.6.** *In a contractible four-sided component of a highest-pressure region in a regularity satisfying double bubble or its exterior, the arcs bordering a least-pressure region are subtended by parallel chords, and the arcs bordering a medium-pressure region are subtended by congruent chords.*

*Proof.* By Lemma 5.2.5, the chords subtending the boundary curves of the component form an isosceles trapezoid inscribed in a circle $\omega$. If the trapezoid is a rectangle, we are done. Otherwise, the two boundary curves $\sigma, \sigma'$ subtended by parallel chords lie on $\omega$, and the other two boundary curves $\mu, \mu'$ are subtended by congruent chords. Because $\sigma, \sigma'$ meet the remainder of $\omega$ at angles *greater* than $2\pi/3$ (namely, $\pi$), the other boundary curves $\mu, \mu'$ of the component bow within $\omega$. In other words, the curvature of $\mu$ is less than the curvature of $\omega$, which equals the curvature of $\sigma$. It follows that $\sigma, \sigma'$ bound a region of less pressure than $\mu, \mu'$ do. □

**Lemma 5.2.7.** *For a minimizing tiling on a torus, the average number of edges per component is exactly six.*

*Proof.* The Euler characteristic on the torus is $v - e + c = 0$, where $v$ is the number of vertices, $e$ is the number of edges, and $c$ is the number of components. By regularity, (Proposition 3.1 and Remark 3.2), $v$, $e$ and $c$ are all finite. Now, let $a$ be the average number of edges per component. Then $c = \frac{2}{a}e$, since each edge is

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

adjacent to two components. Similarly, $v = \frac{2}{3}e$, since each edge is adjacent to two vertices and (by regularity, Proposition 3.1) each vertex is adjacent to three edges. Substituting into the Euler formula, we obtain $(\frac{2}{3} - 1 + \frac{2}{a})e = 0$, from which we obtain $a = 6$. □

**Proposition 5.2.8.** *A minimizing double bubble with a contractible component in a region of least pressure must be either an octagon-square tiling or a hexagon tiling.*

*Proof.* If the pressures of the three regions are equal, then by Proposition 4.5 either the double bubble is a hexagon tiling or the double band; the latter case is impossible because the double bubble must have a contractible component by assumption. Hence, we may assume that the three regions do not all have the same pressure.

If any component in the double bubble plus exterior is a vertex-free band, then its boundary curves are closed geodesics. This either implies that both regions and the exterior have equal pressure, contradicting our previous assumption, or we can slide the band until it collides with some other boundary curve, for a violation of regularity (Remark 3.3). Thus, no component is a vertex-free band.

If any region has contractible complement, then by Proposition 5.1.2, the double bubble is the standard double bubble. Again, the least-pressure region consists solely of noncontractible components, a contradiction. Hence, we may assume that every region has noncontractible complement.

Let $R_1$ be a region of highest pressure. From the previous paragraph and Lemma 4.1, any noncontractible component of $R_1$ is a band. Because $R_1$ is of highest pressure, such a band cannot have any vertices; if it did, then each boundary edge of the band would have positive turning angle, a contradiction. However, we have already shown that no region contains a vertex-free band. Therefore, any component in $R_1$ is contractible. By Proposition 3.7, $R_1$ has at most two contractible components. Also, each component of $R_1$ contains at most four vertices (Remark 3.6). Hence, $R_1$ contains at most eight vertices.

Let $R_2$ be a region of lowest pressure, containing a contractible component with $n$ sides (and perhaps other contractible, or noncontractible, components). This component has least pressure but is not polygonal (because the three pressures are not all equal), so $n > 6$ (Remark 3.6). By Remark 3.4, $n$ is even, implying that $n \geq 8$.

Because every vertex of $R_1$ is a vertex of $R_2$ (and vice versa), and because neither $R_1$ nor $R_2$ contains a vertex-free band, it follows that $R_1$ consists of two contractible four-sided components and that $R_2$ consists of a single contractible curvilinear octagon.

Because no region has contractible complement, $R_2$ and some four-sided component $C$ in $R_1$ must form a chain that wraps around the torus. We now consider two cases.

*Case* 1: $C$ borders two opposite sides of $R_2$. Then just as $R_2$ and $C$ form a chain wrapping around the torus, so too do $R_2$ and the *other* four-sided component of $R_1$ — wrapping around the torus in a different direction. In this case, the double bubble is a tiling. Because $R_1$ and $R_2$ each have eight vertices, $R_3$ must have eight vertices as well, for a total count of 24 vertices. But by Lemma 5.2.7, the average number of vertices per component must be exactly six. Therefore, there are exactly four components, implying that $R_3$ consists of one curvilinear octagon. Therefore, as shown in Figure 9(a), the configuration is an octagon-square tiling.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

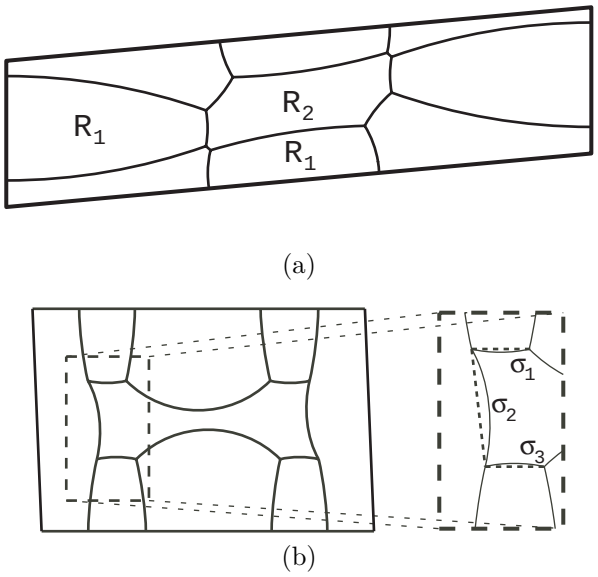

FIGURE 9. Two double bubbles with a purported contractible low-pressure component.

*Case* 2: $C$ borders two sides $\sigma_1, \sigma_3$ of $R_2$ as depicted in Figure 9(b). Let $\sigma_2$ be the side of the eight-sided component between them. By Lemma 5.2.6, the chords subtending $\sigma_1$ and $\sigma_3$ are parallel. Therefore, one of these chords must meet the chord subtending $\sigma_2$ at a nonobtuse angle. But then the corresponding arcs meet at an angle less than $2\pi/3$, a contradiction.

Therefore, if a least-pressure region contains a contractible component, then the double bubble is a hexagon tiling or an octagon-square tiling. □

**Corollary 5.2.9.** *A perimeter-minimizing tiling is either a hexagon tiling or an octagon-square tiling.*

**Lemma 5.2.10.** *Let $\gamma$ be a boundary edge separating two components $X_1$ and $X_2$ in a minimizing double bubble, where both $X_1$ and $X_2$ have different pressures from the third region of the double bubble. Let the two boundary arcs of $X_1$ adjacent to $\gamma$ be $\sigma_1$ and $\sigma_2$, and let the two boundary arcs of $X_2$ adjacent to $\gamma$ be $\mu_1$ and $\mu_2$. (The $\sigma_i$ coincide if $X_1$ has two sides, and the $\mu_i$ coincide if $X_2$ has two sides.) Suppose that $\sigma_1$ and $\sigma_2$ have the following property: they lie on a common arc, and this arc forms an immersed curvilinear digon with $\gamma$. Then $\mu_1$ and $\mu_2$ have this property as well.*

*Proof.* Consider the curvilinear digon bordered by $\gamma$ and the arc containing $\sigma_1$ and $\sigma_2$. We may add a third arc $\mu$ to the curvilinear digon to form an immersed standard double bubble. Because the cocycle condition holds for both the given double bubble and for the immersed standard double bubble, $\mu_1$, $\mu_2$, and $\mu$ have the same (signed) curvatures. Therefore, $\mu_1$ and $\mu_2$ lie on the same circular arc $\mu$, which forms a curvilinear digon with $\gamma$. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Lemma 5.2.11.** *A minimizing swath must be a chain of four-sided components. The exterior is a band with less pressure than either enclosed region of the swath.*

*Proof.* By Proposition 5.2.8, every component of a region of least pressure is noncontractible. This implies two facts: first, because the swath contains contractible components from two regions, the exterior region is the only region of least pressure, as claimed. Second, because the exterior is a region of least pressure, each component of the exterior region is noncontractible. Also, the *complement* of each component in the exterior is noncontractible, because this complement contains the swath formed by the two enclosed regions. Thus, by Lemma 4.1, each component of the exterior is a band. Because the swath formed by the two enclosed regions is connected (Remark 3.3), the exterior region consists of exactly one band, as claimed. Also, the swath cannot contain a contractible cycle of components, because otherwise the cycle would encircle a contractible component of the exterior.

Consider a chain $K$ in the swath. The components in $K$ must alternate between two regions $R_1$ and $R_2$ with higher pressure than the exterior. We will show that the swath contains no additional component of $R_1$ or $R_2$ attached to the chain, as in Figure 10.

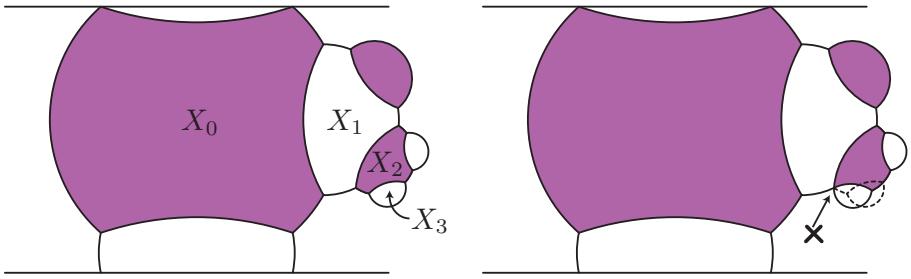

FIGURE 10. Extra components attached to a chain could be slid to create a double bubble violating regularity.

Suppose, for sake of contradiction, that the swath contained an additional component $X_1$ attached to some component $X_0$ in the chain. Either $X_1$ has two sides, or another component $X_2$ attaches to it. In this case, either $X_2$ has two sides, or another component $X_3$ attaches to it. Because the swath contains no contractible cycle, this process terminates after yielding some sequence of components $X_0, X_1, \ldots, X_k$, where $X_k$ has two sides. By Lemma 5.2.10, the boundary edges of $X_{k-1}$ meeting the curvilinear digon $X_k$ lie on the same circle. Therefore, $X_k$ can be slid along the boundary of this circle until it bumps into the boundary of another component, creating a minimizer with an illegal singularity (Proposition 3.1), a contradiction. Therefore, our original assumption was false, and no additional components of $R_1$ or $R_2$ attach to the chain.

Thus, the double bubble is a chain. Because the exterior consists of a single band, each component in the chain is enclosed by four boundary curves: two separating it from the other components of the chain, and two separating it from the exterior. Therefore, the double bubble is a chain of four-sided components. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Lemma 5.2.12.** *Consider a chain of four-sided components in a perimeter-minimizing double bubble. If the arcs separating each component from the exterior of the chain lie on the same circle, then the perimeter of the chain is greater than* 3.

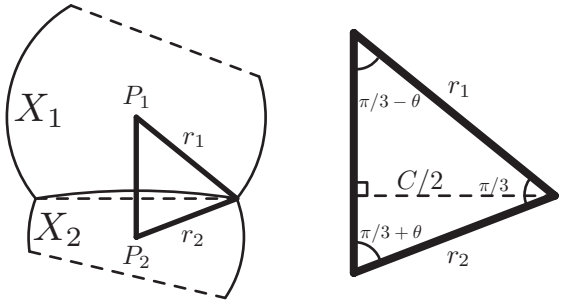

FIGURE 11. Triangulating chains in which opposite arcs are cocircular leads to a perimeter estimate.

*Proof.* Consider two adjacent components $X_1$ and $X_2$ of the chain, as drawn in Figure 11 so that the chord $C$ of the arc separating them is horizontal and lies below $X_1$. Consider the four sides of the polygonal quadrilateral inscribed on the vertices of $X_1$. By Lemma 5.2.11, the chain neighbors a least-pressure region; hence, by Lemma 5.2.6, $C$ and the side opposite it in the quadrilateral are congruent. It follows that $C$ lies below $P_1$, the center of the circle passing through the vertices of $X_1$. Similarly, $C$ lies above the center $P_2$ of the circle passing through the vertices of $X_2$.

We draw the triangle whose vertices are $P_1$, $P_2$, and an endpoint $P_3$ of the chord $C$. The triangle has angles $\pi/3-\theta, \pi/3, \pi/3+\theta$ and side lengths $r_1, r_2, P_1P_2$ for some $\theta, r_1, r_2$. Because $P_1$ and $P_2$ lie on opposite sides of $C$, angles $\angle P_1P_2P_3$ and $\angle P_2P_1P_3$ are acute, implying that $\theta \in (-\pi/6, \pi/6)$. Using the Law of Sines in this triangle, we have $r_1 = P_1P_2 \frac{\sin(\pi/3+\theta)}{\sin(\pi/3)}$. Also, $|C|/2 = r_1 \sin(\pi/3-\theta)$. Hence,

$$|C| = \frac{4}{\sqrt{3}} P_1P_2 \sin(\pi/3+\theta)\sin(\pi/3-\theta).$$

Applying the standard transformation $2\sin x \sin y = \cos(x-y) - \cos(x+y)$ shows that

$$|C| = \frac{2}{\sqrt{3}} P_1P_2(\cos(2\theta) - \cos(2\pi/3)).$$

With the restriction $\theta \in (-\pi/6, \pi/6)$, we see that $|C| \geq \frac{2}{\sqrt{3}} P_1P_2$.

As we vary over pairs of adjacent components, the segments analogous to $\overline{P_1P_2}$ form a closed noncontractible curve with total length greater than or equal to one. Hence, the total length of the chords analogous to $C$ is at least $\frac{2}{\sqrt{3}} > 1$, implying that the total length of the corresponding arcs is also greater than one. Furthermore, the arcs separating the exterior and the chain form two closed noncontractible curves with total length greater than or equal to two. Therefore, the total perimeter of the chain is greater than three. □

**Lemma 5.2.13.** *No asymmetric chain is perimeter minimizing.*

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Proof.* Suppose, for sake of contradiction, that an asymmetric chain is minimizing. By Lemma 5.2.11, it consists of four-sided components, and the exterior is a least-pressure region consisting of a single band. By Lemma 5.2.5, each component of the chain has vertices that form an isosceles trapezoid. If the trapezoid corresponding to each component is a rectangle, then the rectangles (and hence the chain) are all symmetric about a closed geodesic (with the same homology as the chain), a contradiction. Therefore, one of the components has vertices that form a nonrectangular isosceles trapezoid. By Lemma 5.2.5 and Lemma 5.2.6, the arcs separating this component from the least-pressure exterior lie on a single circle. By Lemma 5.2.10, the same is true for all other components in the chain. Applying Lemma 5.2.12, the perimeter of the chain is greater than 3. By Proposition 3.8, the asymmetric chain cannot be minimizing, a contradiction. □

**Lemma 5.2.14.** *A minimizing symmetric chain must be a standard chain.*

*Proof.* By Lemma 5.2.11, such a chain consists of four-sided components, where alternate components lie in each of two regions. Thus, the chain contains an even number of components. By Lemma 5.2.5, each four-sided component is circumscribed about an isosceles trapezoid. Because the chain is symmetric, and using Lemma 5.2.6, we find that each four-sided component must be circumscribed about a rectangle. It easily follows that any pair of adjacent components in the chain is congruent to any other pair.

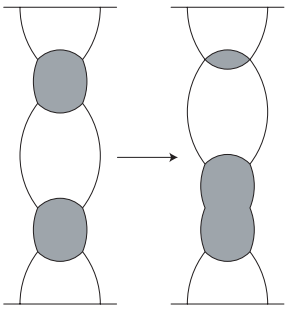

FIGURE 12. Rearranging the components of a symmetric chain with more than two components brings about a violation of regularity, proving that a minimizing chain has two components.

Now if the chain contains more than two components, then rearranging four adjacent components as in Figure 12 maintains area and perimeter while violating regularity, so that the original chain cannot be perimeter minimizing. Therefore, the chain contains exactly two components. No curvilinear quadrilateral lies in a least-pressure region, so the two components of the chain belong to the highest- and medium-pressure regions. Applying the cocycle condition (Proposition 3.1) shows that the chain is standard. □

**Proposition 5.2.15.** *Every perimeter-minimizing swath is a standard chain.*

*Proof.* By Lemma 5.2.11, a minimizing swath must be a chain of four-sided components. By Lemma 5.2.13 a minimizing chain must be symmetric. By Lemma 5.2.14, a minimizing symmetric chain must be a standard chain. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Remark* 5.2.16. While we will show that a minimizing band lens must have the same homology as a shortest closed geodesic (Lemma 5.3.6), we do not have a proof of the analogous fact for minimizing standard chains. However, *Mathematica* plots for perimeter suggest that this property holds at least for the particular tori described by Figure 2.

5.3. **A single band adjacent to a contractible set of components.** Proposition 5.3.5 uses regularity (Proposition 3.1) and Proposition 5.2.8 to show that the only potential minimizer in the class of double bubbles with a single band adjacent to a contractible set of components is the band lens.

Throughout this section, we will consider a proposed minimizer with regions $R_1$, $R_2$ and the exterior, such that $R_1$ is contractible and $R_2$ contains a single band (and possibly some contractible components).

**Lemma 5.3.1.** *In a minimizing double bubble with some contractible region $R_1$, and another region $R_2$ containing a single band, the pressure difference between $R_2$ and the third (exterior) region must be zero, that is, all curves separating $R_2$ from the exterior must be straight line segments.*

*Proof.* Consider a curve separating the band in $R_2$ from the exterior. If it is a straight line segment, the proof is complete, since all curves separating $R_2$ from the exterior have the same curvature by regularity (Proposition 3.1).

If the curve has nonzero curvature, continuously straighten the curve to reduce perimeter, while sliding one component of the boundary of the band in $R_2$ in order to maintain area. Either we will be able to straighten all such pieces while reducing perimeter, or we will first cause a violation of regularity. □

**Lemma 5.3.2.** *In a minimizing double bubble with some contractible region $R_1$, and another region $R_2$ containing a single band, $R_1$ must have higher pressure than each of $R_2$ and the exterior region.*

*Proof.* By Lemma 5.3.1, $R_2$ and the exterior have the same pressure. Since the double bubble is neither a tiling nor the double band, $R_1$ cannot also have the same pressure (Proposition 4.5). Moreover, by Proposition 5.2.8, since $R_1$ is contractible it cannot be a region of least pressure. Thus, $R_1$ must have higher pressure than both $R_2$ and the exterior. □

**Corollary 5.3.3.** *All contractible components of the double bubble plus exterior belong to $R_1$, and $R_2$ consists of a single band.*

*Proof.* By Lemma 5.3.1 and Lemma 5.3.2, $R_2$ and the exterior have equal pressure, less than that of $R_1$. Thus, by Proposition 5.2.8, their components must be non-contractible. Hence only components of $R_1$ can be contractible, and $R_2$ consists of the only noncontractible component of the double bubble — a band. □

**Lemma 5.3.4.** *In a minimizing double bubble with some contractible region $R_1$, and another region $R_2$ containing a single band, all components of $R_1$ are lenses.*

*Proof.* By Lemma 5.3.2, $R_1$ has higher pressure than both $R_2$ and the exterior. By Remarks 3.6 and 3.4, all components of $R_1$ have either two or four sides. We will assume that some component of $R_1$ is a curvilinear quadrilateral $Z$, and show that this leads to a contradiction. Let the four sides of $Z$ be labelled clockwise $x_1$, $y_1$,

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

$x_2$, $y_2$, where $x_1, x_2$ border $R_2$ (a single band, by Corollary 5.3.3) and $y_1, y_2$ border $Y_1, Y_2$ in the exterior.

If $x_1$ and $x_2$ lie on the same side of $R_2$, then either $y_1$ or $y_2$ lies along that same side of the band; the corresponding component $Y_1$ or $Y_2$ is contractible, contradicting Corollary 5.3.3. Otherwise, $x_1$ and $x_2$ lie on opposite sides of $R_2$. In this case, the closure of $R_2 \cup Z$ has contractible complement, so that both $Y_1$ and $Y_2$ are contractible — again contradicting Corollary 5.3.3.

Thus, all components of $R_1$ are curvilinear digons. Now, by Lemma 5.3.1, $R_2$ and the exterior have equal pressure. Therefore, all curves bounding components of $R_1$ have equal, nonzero curvature, and so all curvilinear digons in $R_1$ must be lenses. □

**Proposition 5.3.5.** *A perimeter-minimizing double bubble with a single band adjacent to a contractible set of components must be the band lens.*

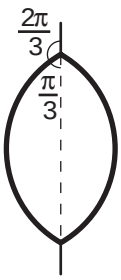

FIGURE 13. Any lens from $R_1$ must be embedded in a closed geodesic.

*Proof.* By Corollary 5.3.3 and Lemma 5.3.4, one region $R_1$ consists only of lenses and the other region $R_2$ consists of a single band. Corollary 5.3.3 also implies that the exterior contains no contractible components. It follows from Lemma 4.1 that the exterior consists solely of bands. Because the double bubble is connected (Remark 3.3), the exterior consists of a single band.

Each lens in $R_1$ has two vertices, each the endpoint of some curve separating $R_2$ and the exterior. By Lemma 5.3.1, these curves are straight line segments. Furthermore, both segments must lie on the line passing through the diameter of the lens, as depicted in Figure 13. Hence, the diameters of the lenses, together with the segments separating $R_2$ from the exterior, form closed geodesics. Since $R_2$ and the exterior each consist of exactly one band, the boundary of the double bubble consists of exactly two closed geodesics, with lenses from $R_1$ embedded in at least one of them. Each of these two closed geodesics has length $L' \geq 1$.

Let the lenses in $R_1$ have total perimeter $p$ and let their diameters have total length $d$. If $d \geq 1$, then the perimeter of the double bubble is at least $(2L' - d) + p > (2L' - d) + 2d \geq 3$, so by Proposition 3.8 the double bubble is not perimeter minimizing. Otherwise, we can move all the lenses so that they are adjacent to each other and embedded in the same closed geodesic, creating a new double bubble enclosing and separating the same areas. If there is more than one lens, then the new double bubble violates regularity (Figure 14), a contradiction. Therefore, the original minimizing double bubble contains exactly one lens, and so must be the band lens. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

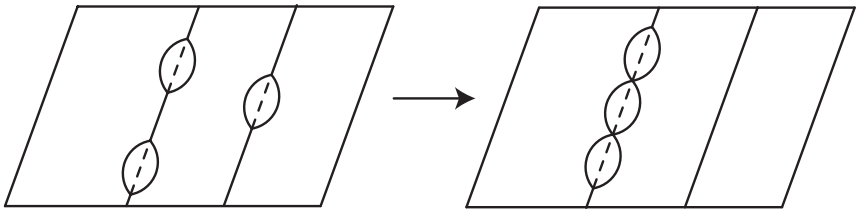

FIGURE 14. Multiple lenses can be slid together to violate regularity. Therefore, there can only be one lens.

**Lemma 5.3.6.** *In a minimizing band lens, the band must have the same homology as a shortest closed geodesic.*

*Proof.* We show that any pair of areas that can be enclosed by a band lens wrapping around a longer direction of the torus can be enclosed by an embedded band lens wrapping around a short direction. Suppose not. By Proposition 3.8, the perimeter of the original band lens is less than or equal to three, so the perimeter of the lens is less than two. Therefore, the diameter of the lens is less than one, and the lens can be embedded on the torus with its axis along a short direction (Remark 2.3.2). Thus, if the band lens wrapping around the short direction does not exist, the closed geodesic not meeting the lens cannot get close enough to make the band thin enough. But if this happens in the short direction, then it will certainly happen for the band lens wrapping around the longer direction, a contradiction.

Hence, if there is a minimizing band lens wrapping around a longer direction of the torus — say, parallel to a closed geodesic of length $L_0 > 1$ — there is a band lens in a short direction of the torus enclosing the same areas. However, the new band lens has perimeter $2(L_0 - 1)$ less than the initial band lens, a contradiction. Therefore, any minimizing band lens has the same homology as a shortest closed geodesic. □

5.4. **Tilings.** This section will show that every perimeter-minimizing tiling is a standard hexagon tiling (Proposition 5.4.23). Corollary 5.2.9 showed that if a tiling is minimizing, then it is a hexagon tiling or an octagon-square tiling. Proposition 5.4.13 shows that every minimizing hexagon tiling is standard, and Proposition 5.4.22 shows that no octagon-square tiling is perimeter minimizing.

**Hexagon tilings**. Lemmas 5.4.3, 5.4.5, and 5.4.6 show that a minimizing hexagon tiling divides the torus into exactly three hexagonal components. Lemma 5.4.9 shows that such a tiling can be transformed without changing perimeter to make the three hexagons congruent translations of each other. By Lemma 5.4.3, the perimeter of the new hexagon tiling is greater than 3 except on the hexagonal torus, implying that the original minimizing hexagon tiling lies on the hexagonal torus. Finally, Proposition 5.4.13 shows that any such hexagon tiling is the standard hexagon tiling.

**Lemma 5.4.1.** *The number of components in a perimeter-minimizing hexagon tiling plus exterior is a multiple of three.*

*Proof.* By Proposition 3.1, there are finitely many vertices in the tiling — say, $v$ — each bordering three distinct regions. Consider any of the three regions $R_i$. Each

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

of its components borders six distinct vertices in the tiling, and each vertex in the tiling borders exactly one component of $R_i$. Hence, $R_i$ contains $v/6$ components. Therefore, $v/6$ is an integer, and there are $3(v/6)$ components in all. □

**Lemma 5.4.2.** *Given $n \geq 3$ real numbers $a_1, \ldots, a_n \in [0, A/3]$ such that $\sum_{i=1}^n a_i = A$, we have $\sum_{i=1}^n \sqrt{a_i} \geq 3\sqrt{A/3}$.*

*Proof.* Because $\sqrt{A}$ is strictly concave, $\sum_{i=1}^n \sqrt{a_i}$ attains its minimum at some vertex of the given domain. At each vertex, three of the $a_i$ equal $A/3$, and the other $a_i$ equal 0. The result follows immediately. □

**Lemma 5.4.3.** *In a hexagon tiling on a torus with area $A$ such that each component has area at most $A/3$, the perimeter of the tiling is greater than or equal to 3. Equality can hold only for a tiling on a hexagonal torus with three components in the tiling plus exterior.*

*Proof.* By Lemma 5.4.1, if there are $n$ components in the tiling plus exterior, then $n \geq 3$. Let $a_1, \ldots, a_n$ be the areas of the $n$ components $C_1, \ldots, C_n$, and let $p_1, \ldots, p_n$ be their perimeters. By the isoperimetric inequality for hexagons, $p_i \geq \sqrt{8\sqrt{3}}\sqrt{a_i}$ for each $i$, with equality if and only if $C_i$ is a regular hexagon.

The total perimeter of the tiling, $\frac{1}{2}\sum_{i=1}^n p_i$, is thus greater than or equal to $\sqrt{2\sqrt{3}}\sum_{i=1}^n \sqrt{a_i}$. By Lemma 5.4.2, $\sqrt{2\sqrt{3}}\sum_{i=1}^n \sqrt{a_i}$ is in turn greater than or equal to $\sqrt{2\sqrt{3}} \cdot 3\sqrt{A/3} = \sqrt{6\sqrt{3}A}$.

Because $A \geq \sqrt{3}/2$ with equality only for the hexagonal torus (Remark 2.1.1), the perimeter of the tiling is at least $\sqrt{6\sqrt{3}A} \geq \sqrt{6\sqrt{3}\frac{\sqrt{3}}{2}} = 3$. The perimeter is exactly 3 only if equality holds in all the intermediate inequalities. In other words, the torus must have area $\sqrt{3}/2$, which only holds for the hexagonal torus; each component must be a regular hexagon and there must be 3 components each with area $A/3$. □

*Remark* 5.4.4. This method of comparing hexagon tilings to tilings of three equal areas was inspired by the result of Hales that the regular hexagon is the most efficient way to tile the plane — not necessarily with polygons — into unit areas [H]. Earlier, Fejes-Tóth proved the result for polygonal tilings ([FT1, Chapter III, Section 9, p. 84] or [FT2, Section 26, Corollary, p. 183] after [FT3]), a result more comparable than Hales' to ours.

**Lemma 5.4.5.** *Consider a hexagon tiling with $n \geq 6$ components in the tiling plus exterior. For each component $H$ in any of the three regions, the perimeter of the tiling exceeds 1 plus the perimeter of $H$.*

*Proof.* We orient the torus so that the edges of the tiling form angles of 0 and $\pm\pi/3$ with the horizontal. Consider $H$ along with the hexagons neighboring it, labelled $H_1, \ldots, H_6$ as in Figure 15.

Although some of $H_1, \ldots, H_6$ may coincide (if $H$ and some component share more than one edge), we claim that $H_2$, $H_4$, and $H_6$ cannot *all* coincide. Assume not. $H_3$ borders $H_2$ from below, and $H_5$ borders $H_6$ from below; because $H_2 = H_6$, we have $H_3 = H_5$. We can likewise show that $H_1$, $H_3$, and $H_5$ are all the same component. The top edge, bottom-right, and bottom-left edges of this component border $H_2 =$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

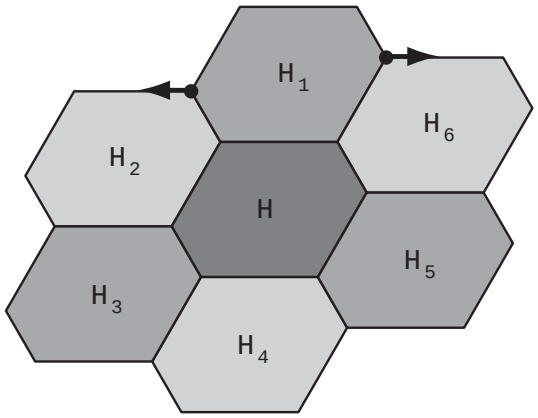

FIGURE 15. A hexagon $H$ on the torus and its six neighbors, shaded according to which regions they lie in. (Some of the six hexagons neighboring $H$ in this picture may actually represent the same component.) In order to find a noncontractible curve not intersecting $H$, we avoid travelling along a downward edge from either of the two marked vertices.

$H_4 = H_6$ (since, as shown in Figure 15, the top edge of $H_3$ borders $H_2$, the bottom-right edge of $H_1$ borders $H_6$, and the bottom-left edge of $H_5$ borders $H_4$); similarly, the other edges of this component border $H$. Thus, $H_1$ only neighbors two distinct components, $H$ and $H_2$. Likewise, $H$ and $H_2$ must only neighbor components in $\{H, H_1, H_2\}$. However, this is impossible; at least one of the $n-3$ hexagons not in $\{H, H_1, H_2\}$ must neighbor some hexagon in $\{H, H_1, H_2\}$. Therefore, our original assumption was false, and we do not have $H_2 = H_4 = H_6$.

Without loss of generality, assume that $H_2 \neq H_6$. Notice also that $H_2 \neq H_5$ and $H_6 \neq H_3$, since alternate sides of $H$ must border different regions (Remark 3.4).

The tiling contains $6n/3$ vertices, which is at least twelve, so we may pick a vertex $v$ not on the boundary of $H$. Starting at $v$, we travel as follows: if we are at one of the vertices marked in Figure 15, travel horizontally as shown in Figure 15; otherwise, travel downward along an edge. It follows that we never travel downward along the edges depicted in Figure 16(a). Furthermore, because $H_6 \notin \{H_2, H_3\}$, we never travel to the right along the edges depicted in Figure 16(b). Similarly, we never travel to the left along the edges depicted in Figure 16(c). It easily follows that we never travel along a horizontal edge only to immediately backtrack along it, and that we never travel along the boundary of $H$ or along any of the edges stemming from $H$.

There are finitely many vertices in the tiling (Proposition 3.1), implying that some portion of our journey begins and ends at the same vertex. Because we never backtrack along a horizontal edge, and because we never travel upward along an edge, this portion of our journey occurs along a closed, noncontractible curve (Figure 17). This curve has length at least 1, and it does not overlap the boundary of $H$, nor does it overlap any of the edges stemming from $H$, which have positive length. Hence, the boundary curves not enclosing $H$ have total length greater than 1, as desired. □

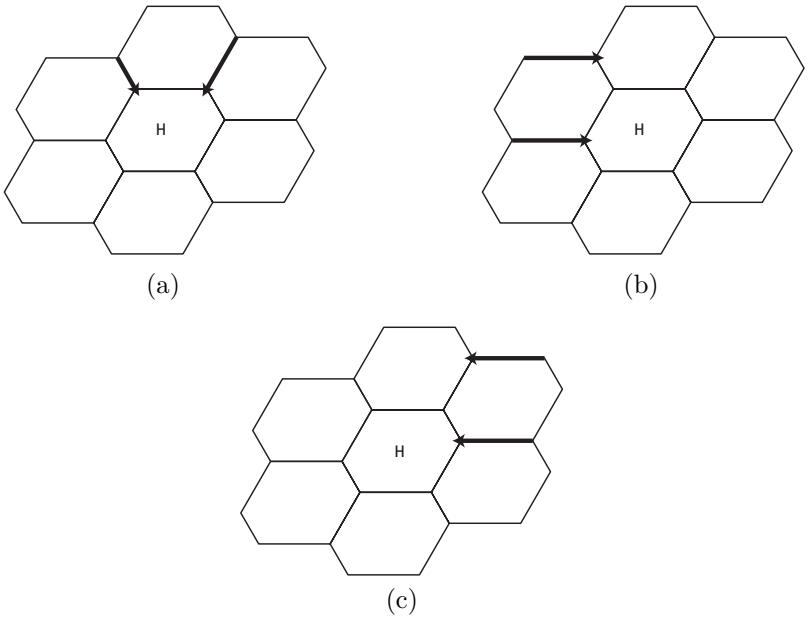

FIGURE 16. In order to bound the perimeter outside any component, we travel along the boundary in an attempt to form a closed noncontractible path. These diagrams show various movements that we do not perform during our journey.

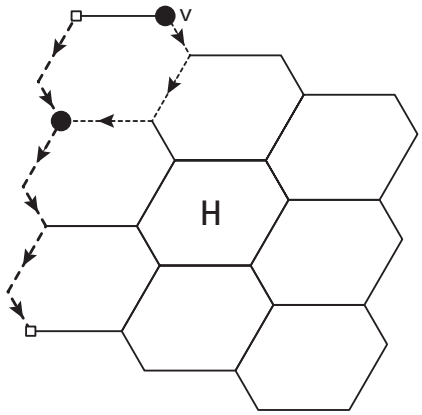

FIGURE 17. Starting at some vertex $v$ and travelling along downward edges — except in those cases where doing so would lead us to a vertex of $H$ — yields a closed, noncontractible curve not passing through the boundary of $H$, for a total perimeter greater than 3 when $H$ is large.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Lemma 5.4.6.** *No hexagon tiling with six or more components in the double bubble plus exterior is perimeter minimizing.*

*Proof.* We consider a hexagon tiling with six or more components. We first consider the case when the area $\alpha$ of some component is at least one-third the total area $A$ of the torus, where $A \geq \sqrt{3}/2$ (Remark 2.1.1). By the isoperimetric inequality for hexagons, the perimeter of $H$ is at least $\sqrt{8\sqrt{3}\alpha} \geq \sqrt{8\sqrt{3}(A/3)} \geq 2$. Therefore, by Lemma 5.4.5, the perimeter of the tiling is greater than $2 + 1 = 3$.

Next consider the case in which each component has area less than $A/3$. Because there are more than three components, by Lemma 5.4.3, the tiling has perimeter greater than 3.

In both cases, it follows by our perimeter bound (Proposition 3.8) that the hexagon tiling is not perimeter minimizing. □

*Remark* 5.4.7. We first attempted to prove Lemma 5.4.6 by shrinking and expanding hexagons to preserve perimeter and areas and eventually contradict regularity. Although the perimeter of the tiling remains the same under such variations, the problem — as Wacharin Wichiramala explained to us — is that it is not always possible to preserve the regions' areas in order to reach such a contradiction.

**Lemma 5.4.8.** *In a hexagon with interior angles of $2\pi/3$, the sum of the lengths of any two adjacent sides equals the sum of the lengths of the opposite pair of adjacent sides.*

*Proof.* Orient the hexagon so that the two sides $p_1, p_2$ not being summed are horizontal, with one pair of remaining sides $q_1, q_2$ on the left and the other pair of remaining sides $r_1, r_2$ on the right. Let $d$ be the distance between $p_1$ and $p_2$. The sides $q_1, q_2$ make an angle of $\pi/6$ with the vertical, so the sum of the lengths of $q_1, q_2$ is $d/\sin(\pi/3)$. Similarly, the sum of the lengths of $r_1, r_2$ is $d/\sin(\pi/3)$. Hence, the two sums are equal, as desired. □

**Lemma 5.4.9.** *Given a hexagon tiling with three components in the tiling plus exterior, there exists a second hexagon tiling with the following properties: the edges of the new tiling are parallel to the edges of the original tiling; the perimeters of the two tilings are equal; and any two parallel edges of the new tiling are congruent. In particular, there exists a second hexagon tiling with the same perimeter, which still contains three components (now of the same area) in the tiling plus exterior.*

*Proof.* To get the desired result, we will find a variation that shrinks and expands hexagons as in Figure 18 to make the three areas equal. Perimeter is unchanged, since $dP/dA$ = curvature = 0 through the whole family of double bubbles in the variation. We show that such a variation exists, and we also give an alternative geometric explanation for why perimeter remains unchanged.

Let $a_i, b_i, c_i$ $(1 \leq i \leq 3)$ be the lengths of the edges in the hexagon tiling as in Figure 19; for each $i \in \{1, 2, 3\}$, the sides of some hexagon $H_i$ are assigned the lengths $a_{i-1}, b_{i-1}, c_{i-1}, a_{i+1}, b_{i+1}, c_{i+1}$ (where indices are taken modulo 3). In this proof, as we modify the hexagon tiling, the values of the $a_i, b_i, c_i$ will change accordingly.

Fix some subscript $i_0$. As shown in Figure 20, for some range of real numbers $\epsilon$ (which we will describe shortly), we may transform our hexagon tiling into another hexagon tiling, so that the edge lengths change as follows: $a_{i_0}, b_{i_0}, c_{i_0}$ change by

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

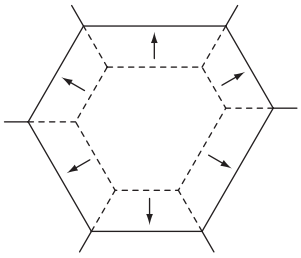

FIGURE 18. Expanding any component in a hexagon tiling or its exterior generates a double bubble enclosing different areas, but does not change perimeter. Hexagons can also be shrunk in a similar fashion.

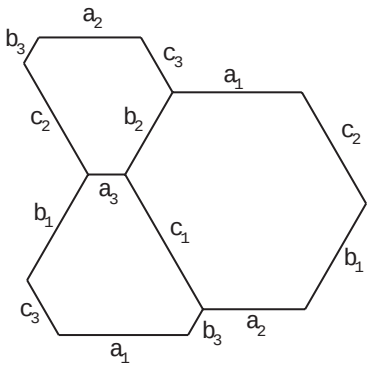

FIGURE 19. A hexagon tiling with three components in the tiling plus exterior.

$-2\epsilon$, and the other $a_i, b_i, c_i$ change by $\epsilon$. More specifically, the range of such $\epsilon$ are those $\epsilon$ for which the side lengths of the resulting tiling are positive; namely, such that $a_i+\epsilon$, $b_i+\epsilon$, and $c_i+\epsilon$ are positive for $i \neq i_0$, and such that $a_{i_0}-2\epsilon$, $b_{i_0}-2\epsilon$, and $c_{i_0}-2\epsilon$ are positive. Adding up the increases and decreases in perimeter shows that under this transformation, the perimeter of the hexagon tiling remains unchanged.

Without loss of generality, assume that $a_1 \geq a_2 \geq a_3$ initially. By Lemma 5.4.8, we have $(a_2 - a_3)/3 = (b_2 - b_3)/3 = (c_2 - c_3)/3$; set $\epsilon$ equal to this common value. As described in the last paragraph, we may shrink $H_3$ so that its edge lengths ($a_i, b_i, c_i$ for $i \neq 3$) decrease by $\epsilon$ and so that $a_3, b_3, c_3$ increase by $2\epsilon$. It is easy to check that this $\epsilon$ is in the allowed range. Furthermore, after this transformation, we have $(a_2, b_2, c_2) = (a_3, b_3, c_3)$.

At this point, we now have $a_1 \geq a_2 = a_3$. We may now set $\epsilon$ equal to $\frac{a_1-a_2}{3}$ and expand $H_1$ so that its edge's lengths increase by $\epsilon$. In the resulting hexagon tiling, we have $(a_1, b_1, c_1) = (a_2, b_2, c_2) = (a_3, b_3, c_3)$, as desired. Furthermore, because the two transformations we used did not change perimeter, the resulting tiling and the initial tiling have the same perimeter. This completes the proof. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

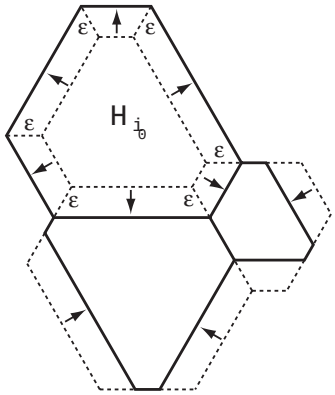

FIGURE 20. In a hexagon tiling with three components in the double bubble plus exterior, we may expand (or shrink) one hexagon so that six edges increase by $\epsilon$ while three edges decrease by $2\epsilon$.

**Lemma 5.4.10.** *Suppose that the hexagonal torus is partitioned into three hexagons with interior angles of $2\pi/3$, where the hexagons are congruent translations of each other. Suppose that the perimeter of the partition is at most 3, or that the sides of the hexagon are parallel to the three short directions. Then the hexagons are regular hexagons of side length $\frac{1}{3}$, with sides parallel to the three short directions of the torus. The total perimeter of the partition is equal to three.*

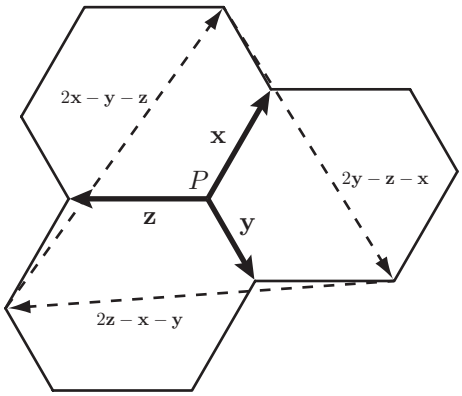

FIGURE 21. In partitions of a torus into three hexagons that are congruent translations of each other, examining three closed geodesics (represented by the dotted vectors) shows that if the hexagons are not regular, then the torus is not hexagonal.

*Proof.* Based on the partition, we draw a fundamental domain of the torus as in Figure 21. Let $P$ be the vertex in the center of the figure where the three hexagons meet; let $\mathbf{x}$, $\mathbf{y}$, $\mathbf{z}$ be the vectors from $P$ outward along the edges of the hexagon tiling, with magnitudes $x, y, z$.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

The three vectors $3\mathbf{x}-3\mathbf{y}$, $3\mathbf{y}-3\mathbf{z}$, $3\mathbf{z}-3\mathbf{x}$ that start at $P$ on the torus also end at $P$. If in addition $\mathbf{x},\mathbf{y},\mathbf{z}$ are parallel to the short directions, it follows easily that $x,y,z$ are multiples of $1/3$. In fact, $x,y,z$ must then equal $1/3$: if any side length were longer, then the area of the three hexagons would exceed that of the torus, which is impossible.

Otherwise, suppose that the perimeter of the partition is at most 3. The three dotted vectors in Figure 21 all begin and end at the same point on the torus. On the hexagonal torus, any such vector has magnitude equal to 1, equal to $\sqrt{3}$, or greater than or equal to 2.

By assumption, the perimeter $3(x+y+z)$ of the partition satisfies

$$\begin{aligned} 3 &\geq 3(x+y+z) \\ &= \frac{3}{4}((2x+y+z)+(2y+z+x)+(2z+x+y)) \\ &\geq \frac{3}{4}(\|2\mathbf{x}-\mathbf{y}-\mathbf{z}\|+\|2\mathbf{y}-\mathbf{z}-\mathbf{x}\|+\|2\mathbf{z}-\mathbf{x}-\mathbf{y}\|). \end{aligned}$$

It follows that the three magnitudes of the three dotted vectors equal one of the following triples: $1,1,1$; $1,1,\sqrt{3}$; or $1,1,2$. The third case is impossible by the triangle inequality.

Without loss of generality, $2\mathbf{z}-\mathbf{x}-\mathbf{y}$ has maximal magnitude among the three vectors (i.e., either 1 or $\sqrt{3}$). Observe that

$$\begin{aligned} 1 &= (2\mathbf{x}-\mathbf{y}-\mathbf{z})\cdot(2\mathbf{x}-\mathbf{y}-\mathbf{z}) \\ &= 4\mathbf{x}\cdot\mathbf{x}+\mathbf{y}\cdot\mathbf{y}+\mathbf{z}\cdot\mathbf{z}-4\mathbf{x}\cdot\mathbf{y}-4\mathbf{x}\cdot\mathbf{z}+2\mathbf{y}\cdot\mathbf{z} \\ &= 4x^2+y^2+z^2-4xy\cos(2\pi/3)-4xz\cos(2\pi/3)+2yz\cos(2\pi/3) \\ &= (x+y+z)^2+3x^2-3yz, \end{aligned}$$

or

$$1-(x+y+z)^2=3(x^2-yz).$$

Solving this and the two analogous equations gives $(x,y,z)=(1/3,1/3,1/3)$ or $(x,y,z)=(\sqrt{3}/9,\sqrt{3}/9,4\sqrt{3}/9)$, depending on whether $2\mathbf{z}-\mathbf{x}-\mathbf{y}$ has magnitude 1 or $\sqrt{3}$. In the latter case, the partition has perimeter $3(x+y+z)=2\sqrt{3}>3$, a contradiction. In the former case, the partition consists of three regular hexagons of side length $\frac{1}{3}$. It easily follows that the sides of the hexagons are parallel to the three short directions of the torus, and that the perimeter of the partition is three. □

**Corollary 5.4.11.** *If a perimeter-minimizing hexagon tiling on the hexagonal torus contains three components in the tiling plus exterior, then the tiling is a standard hexagon tiling.*

*Proof.* By the perimeter bound (Proposition 3.8), the perimeter of the tiling is at most 3. By this result and Lemma 5.4.9, the edges of the hexagon tiling are parallel to the edges of a hexagon tiling satisfying the hypotheses of Lemma 5.4.10. By Lemma 5.4.10, the edges of the new tiling are parallel to the three short directions of the torus. Therefore, so are the edges of the original tiling. □

**Corollary 5.4.12.** *Any standard hexagon tiling has perimeter three.*

*Proof.* By Lemma 5.4.9, a standard hexagon tiling has the same perimeter as a partition of the torus satisfying the conditions of Lemma 5.4.10. By Lemma 5.4.10, this

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

partition has perimeter three, so the original standard hexagon tiling has perimeter three as well. □

**Proposition 5.4.13.** *If a hexagon tiling is perimeter minimizing, then it is the standard hexagon tiling.*

*Proof.* By Lemma 5.4.1, the number of components in a minimizing hexagon tiling plus exterior is divisible by three. By Lemma 5.4.6, a hexagon tiling with six or more components is not perimeter minimizing. Thus, a perimeter-minimizing hexagon tiling must have exactly three components.

By Lemma 5.4.9, a perimeter-minimizing three-component hexagon tiling has the same perimeter as a hexagon tiling in which the area of each component is one-third the area of the torus. By Lemma 5.4.3, this perimeter is greater than three except on the hexagonal torus. Hence, by Proposition 3.8, any perimeter-minimizing three-component hexagon tiling must lie on the hexagonal torus. By Corollary 5.4.11, any such tiling is the standard hexagon tiling. □

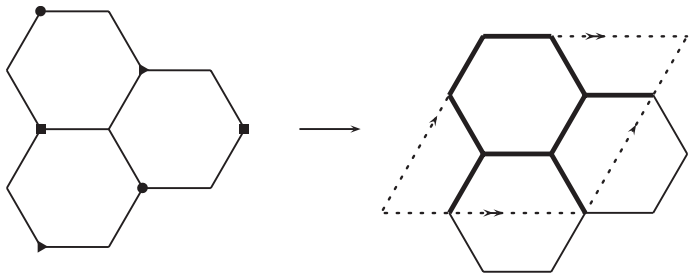

FIGURE 22. This tiling of three congruent hexagons fits on the hexagonal torus and is one of many perimeter-minimizing standard hexagon tilings.

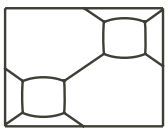

FIGURE 23. An octagon-square tiling always loses to some other double bubble.

**Octagon-square tilings**. Recall that by Definition 7, an octagon-square tiling is a tiling in which one of the three regions consists of two curvilinear quadrilaterals, and each of the other two regions consists of one curvilinear octagon (see Figure 23). The proof that an octagon-square tiling is not perimeter minimizing generalizes an argument described to us by Gary Lawlor eliminating most octagon-square tilings on rectangular tori. Lemma 5.4.14 and Corollary 5.4.15 compare a purported minimizing octagon-square tiling to the band lens in order to establish an upper bound on the length of the interface between the two eight-sided regions. Then, Proposition 5.4.19 and Lemma 5.4.21 establish a lower bound on the length of the same interface by examining projections of the boundary curves of the tiling

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

onto four different directions. Proposition 5.4.22 shows that these upper and lower bounds cannot be satisfied at the same time, implying that no octagon-square tiling is perimeter minimizing.

**Lemma 5.4.14.** *Let $A_1 \leq A_2 \leq A_0$ be three areas whose sum is equal to the area of the torus. Consider a lens enclosing area $A_1$ and with perimeter $P$ and diameter $D$. For any pair of areas from $A_0, A_1, A_2$, a minimizing double bubble enclosing those areas has perimeter less than or equal to*

$$2 + P - D = 2 + \sqrt{A_1 \left( \frac{8\pi}{3} - 2\sqrt{3} \right)},$$

*with equality only if there is a band lens that encloses area $A_1$ in the lens and $A_2$ in the band.*

*Proof.* The expression for $P - D$ is easily derived, and we do not include the proof here (see, for instance, the derivations in Proposition 7.3.1).

Since all of the double bubbles that enclose two of the areas from $\{A_0, A_1, A_2\}$ have the same perimeter, it suffices to prove the claim for a minimizing double bubble enclosing the areas $A_1, A_2$.

If $D \geq 1$, then $2 + P - D > 2 + 2D - D \geq 3$. Thus, by the perimeter bound (Proposition 3.8), $2 + P - D$ exceeds the perimeter of a minimizing double bubble enclosing areas $A_1, A_2$.

Suppose instead that $D < 1$. Then the lens can be embedded on the torus so that its axis lies along a shortest closed geodesic $\gamma_1$ (Remark 2.3.2). There exists another shortest closed geodesic $\gamma_2$ such that $\gamma_1$ and $\gamma_2$ divide the complement of the lens into one part with area $A_0$ and another part with area $A_2$. The portions of these geodesics that lie outside the lens, along with the boundary of the lens, thus form the boundary of a double bubble enclosing areas $A_1, A_2$. The perimeter of the double bubble is at most the total perimeter of $\gamma_2$, the lens, and the portion of $\gamma_1$ lying outside the lens: $1 + P + (1 - D) = 2 + P - D$. Equality holds only if $\gamma_2$ does not intersect the interior of the lens — i.e., only if the double bubble is a band lens. Hence we have the desired result. □

**Corollary 5.4.15.** *Let $A_1 \leq A_2 \leq A_0$ be three areas whose sum is equal to the area of the torus. A minimizing double bubble for any pair of areas from $A_0, A_1, A_2$ has perimeter less than*

$$2 + 2\sqrt{\pi A_1}.$$

*Remark* 5.4.16. Rather than examining partitions of the torus into a lens and two bands as in Lemma 5.4.14, one could prove the corollary directly by examining double bubbles for which the region of area $A_1$ is a circle and the other two regions are bands.

**Lemma 5.4.17.** *If two closed geodesics with lengths $L_1, L_2$ meet at an angle $\phi \in (0, \pi/2]$, then $L_1 + L_2 \geq 1 + 2\cos\phi$. If $L_1, L_2 \in [1, 3/2]$, then $\phi \geq \cos^{-1}(7/9)$.*

*Proof.* The torus can be naturally viewed as the plane with various points identified. In the plane, choose a point $P$ that represents the intersection of the two closed geodesics. Draw a segment $\overline{PQ}$ of length $L_1$ representing the corresponding closed geodesic (on the torus). Similarly, draw a segment $\overline{PR}$ of length $L_2$ representing the other closed geodesic, such that segments $\overline{PQ}$ and $\overline{PR}$ meet at an angle $\phi$.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

Because $Q$ and $R$ represent the same point on the torus, $\overline{QR}$ represents a closed geodesic with length at least 1. Thus, applying the Law of Cosines to triangle $PQR$,

$$1 \leq QR^2 = L_1^2 + L_2^2 - 2L_1L_2\cos\phi = (L_1+L_2)^2 - (2+2\cos\phi)L_1L_2.$$

From $0 \leq (L_1-1)(L_2-1)$, we derive $L_1+L_2-1 \leq L_1L_2$, so that the above inequality becomes

$$1 \leq (L_1+L_2)^2 - (2+2\cos\phi)(L_1+L_2-1)$$

or

$$0 \leq (L_1+L_2-1-2\cos\phi)(L_1+L_2-1).$$

Because $L_1+L_2$ is greater than 1, it must be greater than or equal to $1+2\cos\phi$, as desired.

Suppose now that $L_1, L_2 \in [1, 3/2]$. For a fixed $\phi$, $L_1^2+L_2^2-2L_1L_2\cos\phi$ is convex in each variable $L_1, L_2$, so it is maximized for some $(L_1, L_2)$ with $L_1, L_2 \in \{1, 3/2\}$. For the four pairs $(L_1, L_2)$ satisfying this condition, $L_1^2+L_2^2-2L_1L_2\cos\phi < 1$ when $\cos\phi > 7/9$. Therefore, $\phi \geq \cos^{-1}(7/9)$. □

*Remark* 5.4.18. The next result, Proposition 5.4.19, generalizes a result about "taxicab distances" in the plane. The taxicab distance between any two points, defined with respect to two given orthogonal directions, is the minimum length of a piecewise linear path between them that travels only along the given orthogonal directions (analogous to the streets a taxicab travels on). The length of a segment between two points is at least $\frac{1}{\sqrt{2}}$ times the taxicab distance between them. (Setting $\phi = \pi/2$ in Proposition 5.4.19 gives this estimate.) Given two lines that are *not* orthogonal (to take an extreme example, lines parallel to two short directions on the hexagonal torus), it is useful to have an analogous estimate. We derive such an estimate relating length to the sum of two taxicab distances, one corresponding to each of the two given lines.

**Proposition 5.4.19.** *Given two pairs of orthogonal lines in the plane, suppose that each line in the first pair meets each line in the second pair at an angle $\phi$ or $\pi/2-\phi$, with $\phi \in [\pi/4, \pi/2]$. For any segment $\gamma$, let $T(\gamma)$ be the sum of the lengths of the projections of $\gamma$ onto the four lines. Then*

$$T(\gamma) \leq 2(\sin(\phi/2)+\cos(\phi/2))\,\mathrm{Length}(\gamma).$$

*Proof.* Without loss of generality, assume that one pair of lines are the coordinate axes, and that the other lines lie clockwise angles $\phi$ from the positive $x$- and $y$-axes. Without loss of generality, further assume that $\gamma$ has one endpoint at the origin and points into the first quadrant of the plane.

Let $\mathbf{u}$ be a vector parallel to $\gamma$, whose magnitude equals the length of $\gamma$. Let $\mathbf{v}_1$, $\mathbf{w}_1$, $\mathbf{v}_2$, $\mathbf{w}_2$ be unit vectors pointing along the four given lines, chosen as in Figure 24. Then

$$T(\gamma) = \mathbf{u}\cdot(\mathbf{v}_1+\mathbf{w}_1+\mathbf{v}_2) + |\mathbf{u}\cdot\mathbf{w}_2|.$$

If $\mathbf{u}\cdot\mathbf{w}_2$ is negative, then

$$T(\gamma) = \mathbf{u}\cdot(\mathbf{v}_1+\mathbf{w}_1+\mathbf{v}_2-\mathbf{w}_2) \leq \|\mathbf{u}\|\|\mathbf{v}_1+\mathbf{w}_1+\mathbf{v}_2-\mathbf{w}_2\|,$$

with equality when $\mathbf{u}$ is parallel to $\mathbf{v}_1+\mathbf{w}_1+\mathbf{v}_2-\mathbf{w}_2$. When this is true, $\mathbf{u}$ bisects the angle formed by $\mathbf{v}_1$ and $\mathbf{v}_2$, and it is easy to compute $\mathbf{u}\cdot\mathbf{v}_1 = \mathbf{u}\cdot\mathbf{v}_2 = \|\mathbf{u}\|\cos(\phi/2)$ and $\mathbf{u}\cdot\mathbf{w}_1 = -\mathbf{u}\cdot\mathbf{w}_2 = \|\mathbf{u}\|\sin(\phi/2)$. Hence, when $\mathbf{u}\cdot\mathbf{w}_2$ is negative,

$$T(\gamma) \leq \|\mathbf{u}\|(2\cos(\phi/2)+2\sin(\phi/2)) = 2(\cos(\phi/2)+\sin(\phi/2))\mathrm{Length}(\gamma).$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

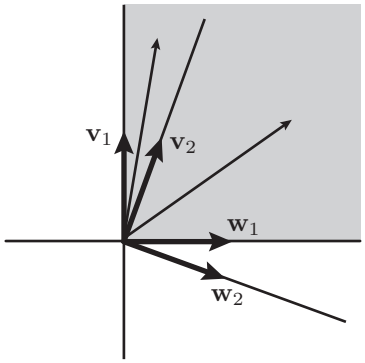

FIGURE 24. If a vector in the first quadrant has fixed magnitude, then the sum of its projections onto the four directions $\mathbf{v}_i$, $\mathbf{w}_i$ drawn above attains a local maximum in two places: when it bisects the angle between $\mathbf{v}_1$ and $\mathbf{v}_2$, and when it bisects the angle between $\mathbf{w}_1$ and $\mathbf{v}_2$.

Similarly, if $\mathbf{u} \cdot \mathbf{w}_2$ is nonnegative, then $T(\gamma)/\|\mathbf{u}\|$ is maximized when $\mathbf{u}$ bisects the angle formed by $\mathbf{w}_1$ and $\mathbf{v}_2$. We then find that

$$\begin{aligned} T(\gamma) &\leq 2(\cos(\pi/4 - \phi/2) + \sin(\pi/4 - \phi/2))\text{Length}(\gamma) \\ &\leq 2(\cos(\phi/2) + \sin(\phi/2))\text{Length}(\gamma), \end{aligned}$$

where the second inequality is true because $\phi \in [\pi/4, \pi/2]$. □

**Lemma 5.4.20.** *If* $\cos^{-1}(7/9) \leq \phi \leq \pi/2$, *then*

$$\frac{\max\{2, 1 + 2\cos\phi\}(1 + \sin\phi) - 3}{\sin\left(\frac{\max\{\phi, \pi/2-\phi\}}{2}\right) + \cos\left(\frac{\max\{\phi, \pi/2-\phi\}}{2}\right) - 1} \geq 2.$$

*Proof.* The denominator of the left-hand side is at most $\sqrt{2} - 1$. For $\cos^{-1}(7/9) \leq \phi \leq \pi/4$, we have $\cos\phi \geq \sqrt{2}/2$ and $\sin\phi > 2 - \sqrt{2}$. Hence, the numerator of the left-hand side is greater than $2\sqrt{2} - 2$. Therefore, the left-hand side is greater than 2 when $\phi \leq \pi/4$.

For $\pi/4 \leq \phi \leq \pi/3$, $\max\{2, 1+2\cos\phi\} = 1+2\cos\phi$ and $\max\{\phi, \pi/2-\phi\} = \phi$. It is easy to check that on the interval $\phi \in [\pi/4, \pi/3]$, the numerator of the left-hand side is decreasing while the denominator is increasing. Because the inequality holds when $\phi = \pi/3$ (with equality), it holds along the entire interval.

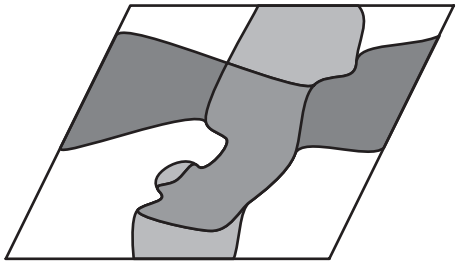
For $\pi/3 \leq \phi \leq \pi/2$, $\max\{2, 1 + 2\cos\phi\} = 2$ and $\max\{\phi, \pi/2 - \phi\} = \phi$. Clearing the denominator of the desired inequality, then simplifying, yields the following inequalities (each equivalent to the desired inequality):

$$\begin{aligned} 2\sin\phi - 1 &\geq 2\sin(\phi/2) + 2\cos(\phi/2) - 2, \\ 4\sin(\phi/2)\cos(\phi/2) - 1 &\geq 2\sin(\phi/2) + 2\cos(\phi/2) - 2, \\ (2\sin(\phi/2) - 1)(2\cos(\phi/2) - 1) &\geq 0. \end{aligned}$$

The last inequality holds for $\pi/3 \leq \phi \leq \pi/2$. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

**Lemma 5.4.21.** *Let $\mathcal{B}_1$ and $\mathcal{B}_2$ be the boundaries of two bands with distinct homologies, where $\mathcal{B}_1$ and $\mathcal{B}_2$ may overlap each other nontrivially (see Figure 25). If the length of $\mathcal{B}_1 \cup \mathcal{B}_2$ does not exceed 3, then the length of $\mathcal{B}_1 \cap \mathcal{B}_2$ is greater than or equal to 2.*



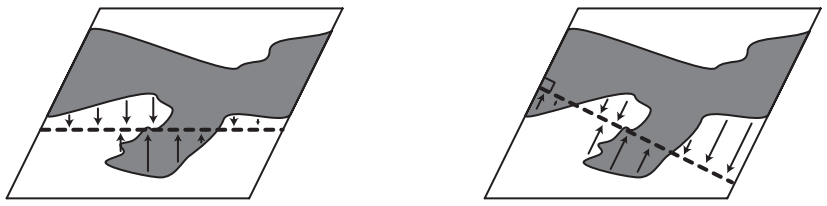


FIGURE 25. Given two bands with overlapping boundary, we can project the boundaries onto various directions to show that the length of the overlap is large. (Above, the bands are filled with dark and light shades, with a medium shade along their intersection.)

*Proof.* Assume that the length of $\mathcal{B}_1 \cup \mathcal{B}_2$ is as at most 3, and let $\gamma_1, \ldots, \gamma_k$ be the components of $\mathcal{B}_1 \cap \mathcal{B}_2$. For $i = 1, 2$, let $L_i$ be the length of the closed geodesic $g_i$ with the same homology as the components of $\mathcal{B}_i$. Observe that $L_i \leq 3/2$, because otherwise $\mathcal{B}_i$ would have length greater than 3. Let $g_1$ and $g_2$ meet each other at an angle $\phi \in (0, \pi/2]$.

Below, we will take each closed curve in $\mathcal{B}_1$ and project it onto two directions — onto the direction of $g_1$ (Figure 26(a)) and onto the direction orthogonal to $g_2$ (Figure 26(b)). We will also take similar projections of the components of $\mathcal{B}_2$. By analyzing these projections' effects on various pieces of $\mathcal{B}_1 \cup \mathcal{B}_2$, we will obtain our desired inequality.

For each $\gamma_i$, let $T(\gamma_i)$ be the sum of the projection of $\gamma_i$ onto four directions: the two directions of the closed geodesics $g_1$ and $g_2$, and the two directions orthogonal to these closed geodesics.

(a) (b)

FIGURE 26. By projecting each component of the boundary of the bands in two directions, we bound the length of the intersection of the two boundaries.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

Take a component of $\mathcal{B}_1$, and project it onto the direction of $g_1$ and onto the direction orthogonal to $g_2$. The first projection has length at least $L_1$, and the second projection has length at least $L_1 \sin\phi$. Project the other component of $\mathcal{B}_1$ in a similar fashion.

Likewise, project each component of $\mathcal{B}_2$ onto the direction of $g_2$ and onto the direction orthogonal to $g_1$. In all, the projections of the components of $\mathcal{B}_1$ and $\mathcal{B}_2$ have total length greater than or equal to

$$2(L_1 + L_2)(1 + \sin\phi).$$

Each component of $\mathcal{B}_1 \cup \mathcal{B}_2 - \mathcal{B}_1 \cap \mathcal{B}_2$ is projected exactly twice, so they contribute at most

$$2 \cdot \text{Length}(\mathcal{B}_1 \cup \mathcal{B}_2 - \mathcal{B}_1 \cap \mathcal{B}_2)$$

to the total length of the projections. Each $\gamma_i$, on the other hand, contributes at most $T(\gamma_i)$. Therefore,

$$\begin{aligned} 2(L_1 + L_2)(1 + \sin\phi) &\leq 2 \cdot \text{Length}(\mathcal{B}_1 \cup \mathcal{B}_2 - \mathcal{B}_1 \cap \mathcal{B}_2) + \sum_{i=1}^{k} T(\gamma_i) \\ &\leq 2\left(3 - \sum_{i=1}^{k} \text{Length}(\gamma_i)\right) + \sum_{i=1}^{k} T(\gamma_i). \end{aligned}$$

We estimate the two sides of this inequality as follows. First, $L_1 + L_2 \geq 2$, and by Lemma 5.4.17, $L_1 + L_2 \geq 1 + 2\cos\phi$. Hence,

$$2\max\{2, 1 + 2\cos\phi\}(1 + \sin\phi) \leq 2(L_1 + L_2)(1 + \sin\phi).$$

Second, from the two pairs of orthogonal directions we project onto, we can choose one direction from each pair so that they meet at an angle of $\max\{\phi, \pi/2 - \phi\} \in [\pi/4, \pi/2]$. Applying Proposition 5.4.19 then shows that

$$2\left(3 - \sum_{i=1}^{k} \text{Length}(\gamma_i)\right) + \sum_{i=1}^{k} T(\gamma_i)$$

is at most

$$6 + \left(2\sin\left(\frac{\max\{\phi, \pi/2 - \phi\}}{2}\right) + 2\cos\left(\frac{\max\{\phi, \pi/2 - \phi\}}{2}\right) - 2\right) \sum_{i=1}^{k} \text{Length}(\gamma_i).$$

Therefore, to prove that $\sum_{i=1}^{k} \text{Length}(\gamma_i) \geq 2$, it suffices to prove that

$$\frac{\max\{2, 1 + 2\cos\phi\}(1 + \sin\phi) - 3}{\sin\left(\frac{\max\{\phi, \pi/2 - \phi\}}{2}\right) + \cos\left(\frac{\max\{\phi, \pi/2 - \phi\}}{2}\right) - 1} \geq 2.$$

By Lemma 5.4.17, $\cos^{-1}(7/9) \leq \phi$; also, by definition, $\phi \leq \pi/2$. By Lemma 5.4.20, the above inequality holds for such $\phi$. □

**Proposition 5.4.22.** *No octagon-square tiling is perimeter minimizing.*

*Proof.* Let $\mathcal{B}_1$ be the boundary of the band enclosing one eight-sided region and one four-sided component (Figure 27(a)). Let $\mathcal{B}_2$ be the boundary of the band enclosing the same eight-sided region and the other four-sided component (Figure 27(b)). If the length of $\mathcal{B}_1 \cup \mathcal{B}_2$ is greater than 3, then by the perimeter bound (Proposition 3.8), the octagon square is not perimeter minimizing.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

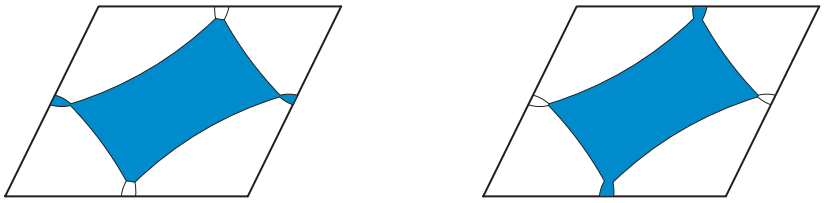

FIGURE 27. Given the above octagon-square tiling, the boundaries of the two colored bands either have a union with length greater than three, or an intersection with length greater than or equal to two. In both cases, it can be shown that the tiling is not perimeter minimizing.

Otherwise, by Lemma 5.4.21, the length of $\mathcal{B}_1 \cap \mathcal{B}_2$ is at least 2. Let $A_1$ be the area of the region containing the four-sided components. By the isoperimetric inequality for the plane, the perimeter of this region is at least $2\sqrt{\pi A_1}$. Therefore, the perimeter of the octagon-square tiling is at least $2 + 2\sqrt{\pi A_1}$. By Corollary 5.4.15, the tiling is not a minimizer. □

**Proposition 5.4.23.** *The only tiling that can be perimeter minimizing is the standard hexagon tiling.*

*Proof.* By Corollary 5.2.9, the tiling must be a hexagon tiling or an octagon-square tiling. By Proposition 5.4.22, no octagon-square tiling is perimeter minimizing. By Proposition 5.4.13, the only minimizing hexagon tiling is the standard hexagon tiling. □

## 6. Perimeter-minimizing double bubbles on the flat two-torus

The Main Theorem characterizes the perimeter-minimizing double bubbles on all flat two-tori, as depicted in Figure 1. Corollaries 6.3 and 6.5 characterize the minimizing double bubbles on the flat infinite cylinder and the flat infinite strip with free boundary. Remark 6.7 makes a conjecture about the double bubble problem on the closely related Klein bottle.

**Main Theorem 6.1.** *A perimeter-minimizing double bubble on a flat two-torus is of one of the following five types (perhaps after relabelling the three regions), depending on the areas to be enclosed:*

(i) *the standard double bubble,*
(ii) *a standard chain,*
(iii) *the band lens,*
(iv) *the double band, or*
(v) *the standard hexagon tiling (only for the hexagonal torus).*

*Proof.* Proposition 4.6 shows that a minimizer must be a contractible double bubble, a tiling, a swath, a band adjacent to a set of components whose union is contractible, or the double band (after perhaps relabelling the two regions and the exterior).

By Proposition 5.1.2, the standard double bubble is the only possible contractible minimizer. By Proposition 5.2.15, a standard chain is the only possible minimizer

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

among swaths. By Proposition 5.3.5, the band lens is the only possible minimizer among bands adjacent to a set of components whose union is contractible. By Proposition 5.4.23, the standard hexagon tiling (on the hexagonal torus) is the only possible minimizing tiling. □

*Remark* 6.2. Using the phase portrait computations of Section 8, it can be confirmed that all five types of minimizers do occur.

**Corollary 6.3.** *A perimeter-minimizing double bubble on the flat infinite cylinder is of one of the following four types, depending on the areas to be enclosed:*

(i) *the standard double bubble,*
(ii) *a standard chain,*
(iii) *the band lens, or*
(iv) *the double band.*

*Proof.* Without loss of generality, assume that the cylinder has circumference 1. Let $\Sigma$ be a perimeter-minimizing double bubble on the cylinder that is not of one of the four types listed above. Because $\Sigma$ has finite perimeter, it can be placed on some long rectangular torus (for example, one with length greater than 3). Then by Theorem 6.1, there exists a double bubble $\Sigma'$ on the torus enclosing the same areas as $\Sigma$ but with less perimeter. Because the torus has length greater than 3, and because $\Sigma'$ has perimeter less than or equal to 3, it is contractible or wraps around a short direction of the torus. Therefore, $\Sigma'$ can be placed on the cylinder, and $\Sigma$ cannot be perimeter minimizing. □

**Corollary 6.4.** *Every minimizing double bubble on the infinite cylinder has a line of reflective symmetry that is perpendicular to a shortest closed geodesic, or is congruent to a double bubble with this property.*

*Proof.* Given a minimizing standard double bubble, it can be rotated so that its axis of symmetry is perpendicular to a shortest closed geodesic. Each of the other minimizers in Corollary 6.3 has a line of reflective symmetry with the required property. (A standard chain on the infinite cylinder has a line of reflective symmetry that is parallel to a shortest closed geodesic, but it also has two lines of reflective symmetry perpendicular to a shortest closed geodesic.) □

**Corollary 6.5.** *Any minimizing double bubble on the flat infinite strip with free boundary is the quotient of a minimizing double bubble on an infinite cylinder (with twice the width of the strip) by a reflection across one of its lines of symmetry, using the free boundary of the strip to complete the double bubble, as in Figure 28.*

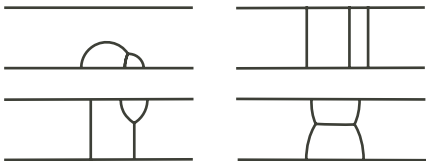

FIGURE 28. The four perimeter-minimizing double bubbles on the flat infinite strip with free boundary are each half of some perimeter-minimizing double bubble on the infinite cylinder.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Proof.* The infinite strip is the quotient space of the infinite cylinder by some reflection. Hence we can think of the infinite cylinder as a double cover of the infinite strip. Lifting a minimizer $\Sigma$ on the strip yields a double bubble $\Sigma'$ on the cylinder with twice the perimeter and enclosed areas as $\Sigma$. If $\Sigma'$ is a minimizing double bubble, then we are done. Otherwise, by Corollary 6.4, there exists a minimizer $\Gamma'$ that encloses the same areas as $\Sigma'$ and that has at least one line of reflective symmetry perpendicular to a shortest closed geodesic. Quotienting by the corresponding reflection yields the original infinite strip with free boundary, along with a new double bubble $\Gamma$ enclosing the same areas as $\Sigma$ with less perimeter, a contradiction. □

*Remark* 6.6. For finite rectangular cylinders with free boundary (i.e., the quotient space of a rectangular torus by some reflection), a result analogous to Corollary 6.5 holds if the distance between the two components of the boundary is sufficiently small with respect to the length of each component of the boundary.

*Remark* 6.7 (Klein bottles). We conjecture that perimeter-minimizing double bubbles on the flat Klein bottle are of virtually the same form as on the flat torus. Like the flat torus, we can represent the flat Klein bottle as a planar parallelogram with opposite sides identified and no angle less than 60 degrees, except that we identify the top and bottom sides with a flip. Because of this flip, on a Klein bottle with reasonably long top and bottom, any minimizing double band is bounded by two closed geodesics each of length 2, and has total perimeter 4 (instead of 3). This is an important difference, and for proofs on the torus where we required a perimeter bound of 3, it will be necessary to modify our approach to accommodate the higher bound for the Klein bottle. Note also that the placement of perimeter-minimizing double bubbles on a wide Klein bottle is less flexible than on a torus. The standard chain, band lens, and double band must all be oriented symmetrically about one of the two unique shortest closed geodesics of a wide Klein bottle (which are always vertical). However, all of the conjectured minimizers (including the standard hexagon tiling) do remain well defined, so long as they are placed carefully.

We also conjecture that the perimeter-minimizing double bubbles on the infinite cylinder (which can be thought of as an infinitely long rectangular torus) carry over in the analogous space corresponding to the Klein bottle, that is, a Möbius strip of infinite length — the surface between two horizontal lines in the plane, where the lines are identified with a flip. Here the same comments apply, but the absence of tilings may make the full solution more accessible.

## 7. Formulas for perimeter and area

This section gives formulas for the areas of the enclosed regions and the perimeters of the four potential minimizers different from the double band: the standard double bubble (Proposition 7.1.1), the standard chain (Propositions 7.2.1, 7.2.2), the band lens (Proposition 7.3.1), and the standard hexagon tiling (Proposition 7.4.1). In addition, Lemmas 7.2.4 and 7.4.5 prove that when a standard chain with axis-length one or a standard hexagon tiling *seems* to be minimizing, based on formal perimeter calculations that we can perform even if the double bubble actually does not exist on a given torus, then the double bubble actually exists and is minimizing. As described in Section 8, we use these formulas and results to produce the phase portraits in Figure 2.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Remark* 7.1. We begin by stating a few simple geometric formulas that describe circular arcs meeting chords. Given a circular arc subtended by a chord of length $C$ that it meets at an angle $\theta$, the area between the arc and the chord, the length of the arc, and the radius of the circle are given by

$$A(\theta, C) = \frac{C^2(\theta - \sin\theta\cos\theta)}{4\sin^2\theta}, \tag{7.1}$$

$$L(\theta, C) = \frac{C\theta}{\sin\theta}, \tag{7.2}$$

$$R(\theta, C) = \frac{C}{2\sin\theta}. \tag{7.3}$$

7.1. **Formulas for the standard double bubble.** Proposition 7.1.1 gives formulas for perimeter and area of the standard double bubble. These formulas first appeared in [F, Section 2].

**Proposition 7.1.1.** *Let $R_1$ and $R_2$ be the regions of higher and lower pressure enclosed in a standard double bubble. The area and perimeter formulas of a standard double bubble in terms of the separating chord length $C$ and the angle $\theta$ at which it meets the interior arc are*

$$\begin{aligned} A_{R_1}(\theta, C) &= A(2\pi/3 - \theta, C) + A(\theta, C), \\ A_{R_2}(\theta, C) &= A(2\pi/3 + \theta, C) - A(\theta, C), \\ P(\theta, C) &= L(2\pi/3 + \theta, C) + L(2\pi/3 - \theta, C) + L(\theta, C). \end{aligned}$$

*Proof.* The arc between $R_1$ and the exterior meets the separating chord $C$ at $\frac{2\pi}{3} - \theta$, and the arc between $R_2$ and the exterior meets the separating chord $C$ at $\frac{2\pi}{3} + \theta$. The given formulas follow immediately. □

7.2. **Formulas for the standard chain.** To parameterize the standard chain, we distinguish between those in which the enclosed regions have unequal pressure (Proposition 7.2.1) and those in which the enclosed regions have equal pressure (Proposition 7.2.2).

**Proposition 7.2.1.** *Consider a standard chain with axis-length $L_0$ and with two components of unequal pressure. Let $R_1$ and $R_2$ be the enclosed regions, and suppose that $R_1$ has greater pressure than $R_2$. Let $C_1$ be the length of either chord subtending an arc separating $R_1$ from the exterior, where the chord and arc meet at (interior) angles $\theta_1$. (See Figure 29.) The area and perimeter formulas are*

$$\begin{aligned} A_{R_1}(\theta_1, C_1) &= 2A(\theta_1, C_1) + 2A(\pi/6 - \theta_1, C_3) + C_1C_3, \\ A_{R_2}(\theta_1, C_1) &= 2A(\pi/3 - \theta_1, C_2) - 2A(\pi/6 - \theta_1, C_3) + C_2C_3, \\ P(\theta_1, C_1) &= 2L(\theta_1, C_1) + 2L(\pi/3 - \theta_1, C_2) + 2L(\pi/6 - \theta_1, C_3), \end{aligned}$$

*where $C_2$ and $C_3$ are given by*

$$\begin{aligned} C_2 &= L_0 - C_1, \\ C_3 &= \frac{C_1(L_0 - C_1)\sin(\frac{\pi}{6} - \theta_1)}{(L_0 - C_1)\sin\theta_1 - C_1\sin(\frac{\pi}{3} - \theta_1)}. \end{aligned}$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

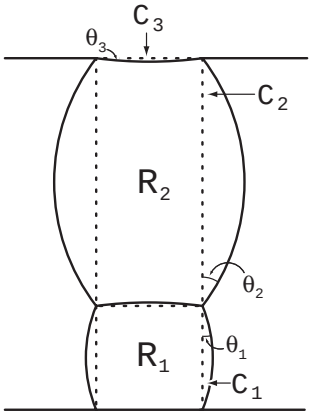

FIGURE 29. This picture illustrates the basic parameters involved in computing perimeter and area for a standard chain.

*A standard chain with these parameters exists on an infinite cylinder of circumference $L_0$ if and only if $C_1 \in (0, \frac{1}{2}L_0)$ and $\theta_1 \in (\sin^{-1}(C_1/L_0), \pi/6)$.*

*Proof.* Let $R_0$ be the low-pressure exterior region. By the results of Section 5.2, the vertices of $R_1$ and $R_2$ form a rectangle. For $i = 1, 2$, let either arc separating $R_i$ from $R_0$ have curvature $\kappa_i$ and radius of curvature $r_i = 1/\kappa_i$, let $C_i$ denote the length of the chord with the same endpoints as the arc, and let $\theta_i$ be the (interior) angle the chord and the arc make. Define $\kappa_3$, $r_3$, $C_3$, and $\theta_3$ similarly with respect to the interface between $R_1$ and $R_2$.

Because the arcs in the boundary of the chain meet at $2\pi/3$, we have

$$\theta_2 = \pi/3 - \theta_1 \qquad \text{and} \qquad \theta_3 = \pi/6 - \theta_1.$$

Of course,

$$C_2 = L_0 - C_1.$$

Also, by the Extended Law of Sines,

$$C_i = 2r_i \sin\theta_i \qquad \text{for } i = 1, 2, 3,$$

allowing us to solve for $r_1$ and $r_2$ in terms of $\theta_1$ and $C_1$. By the cocycle condition (as in Proposition 3.1),

$$-\frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} = -\kappa_1 + \kappa_2 + \kappa_3 = 0,$$

and we may solve for $r_3$ in terms of $r_1$ and $r_2$. These equations allow us to find $C_3$ in terms of $\theta_1$ and $C_1$:

$$\begin{aligned} C_3 &= 2\frac{1}{1/r_1 - 1/r_2}\sin\theta_3 = \frac{2r_1r_2}{r_2 - r_1}\sin\theta_3 \\ &= \frac{C_1C_2}{C_2\sin\theta_1 - C_1\sin\theta_2}\sin\theta_3 = \frac{C_1(L_0 - C_1)\sin(\pi/6 - \theta_1)}{(L_0 - C_1)\sin\theta_1 - C_1\sin(\pi/3 - \theta_1)}. \end{aligned}$$

It remains to show that $C_1 \in (0, L_0/2)$, $\theta_1 \in (\sin^{-1}(C_1/L_0), \frac{\pi}{6})$, and that a corresponding standard chain exists (on some infinite cylinder) if these bounds hold.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

Because $r_2 > r_1$ and $\theta_2 > \theta_1$, we have $L_0 - C_1 = C_2 = 2r_2 \sin\theta_2 > 2r_1 \sin\theta_1 = C_1$, proving the bound on $C_1$. The upper bound on $\theta_1$ holds because $\pi/6 - \theta_1 = \theta_3 > 0$.

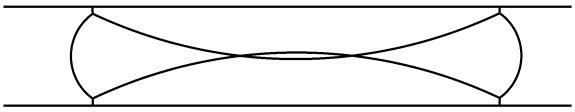

FIGURE 30. If the angles and lengths in the parameterization of a standard chain do not meet certain bounds, then the boundary arcs of the chain intersect each other.

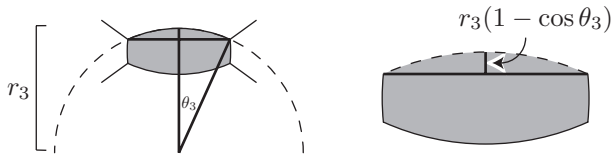

FIGURE 31. The arcs separating the components enclosed in a standard chain cannot intersect each other, yielding bounds on the parameters used to describe standard chains.

Given $C_1 \in (0, L_0/2)$ and $0 < \theta_1 < \pi/6$, a corresponding standard chain exists (on some infinite cylinder) if and only if it can be drawn so that the arcs separating $R_1$ and $R_2$ do not intersect. Consider one of these arcs. As shown in Figure 31, the distance between the midpoint of the arc and the chord subtending the arc is $r_3 - r_3\cos\theta_3$. The two arcs separating $R_1$ and $R_2$ do not intersect each other if and only if this distance is less than $\frac{1}{2}C_2$ — that is, if and only if

$$r_3(1-\cos\theta_3) < \frac{1}{2}C_2.$$

(This inequality fails if and only if the arcs intersect each other as in Figure 30.) Writing $r_3$, $\theta_3$, and $C_2$ in terms of $C_1$ and $\theta_1$, this inequality becomes (after much simplification)

$$C_1 < L_0 \sin\theta_1$$

or $\theta_1 > \sin^{-1}(C_1/L_0)$. □

**Proposition 7.2.2.** *Consider a standard chain with axis-length $L_0$ and with two regions $R_1$ and $R_2$ of equal pressure. The area and perimeter formulas are*

$$\begin{aligned} A_{R_1}(C_3) = A_{R_2}(C_3) &= \frac{2\pi - 3\sqrt{3}}{24}L_0^2 + \frac{1}{2}L_0 C_3 \\ P(C_3) &= \frac{2\pi}{3}L_0 + 2C_3, \end{aligned}$$

*where $C_3$ is the length of the chord separating $R_1$ from $R_2$.*

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

*Proof.* For $i = 1, 2, 3$, define $\kappa_i$, $r_i$, $C_i$, and $\theta_i$ as in the first paragraph of the proof of Proposition 7.2.1. (Figure 29 shows many of these variables, although the standard chain in the figure does not contain two regions of equal pressure.)

Observe that $\kappa_1 = \kappa_2$ and hence $r_1 = r_2$. Also, $\theta_3 = 0$ and $\theta_1 = \theta_2 = \pi/6 - \theta_3 = \pi/6$. Therefore, $C_1 = 2r_1 \sin\theta_1 = 2r_2 \sin\theta_2 = C_2$, implying that $C_1 = C_2 = \frac{1}{2}L_0$ and $r_1 = r_2 = \frac{1}{2}L_0/(2\sin(\pi/6)) = \frac{1}{2}L_0$.

Although $C_1$ and $C_2$ are uniquely determined, $C_3$ is not. Still, because all other arc lengths and angles in the chain are fixed, we have simple formulas expressing the areas and perimeters of such chains in terms of $C_3$. Given the fixed angles and chord lengths found earlier, we have $A_{R_1}(C_3) = A_{R_2}(C_3) = 2A(\pi/6, \frac{L_0}{2}) + (\frac{1}{2}L_0)C_3$ and $P(C_3) = 4L(\pi/6, \frac{L_0}{2}) + 2C_3$. Using (7.1)–(7.2) to evaluate these expressions yields the desired formulas. □

*Remark* 7.2.3. The plots based on this parameterization prove the existence of a family of standard chains with fixed axis-length. In particular, we know that there exists a family of standard chains that wrap around a short direction of the torus.

**Lemma 7.2.4.** *Consider any standard chain on the unit-circumference cylinder enclosing areas $A_1, A_2$, and any torus with area greater than $A_1 + A_2$. The perimeter of the chain is greater than or equal to that of the minimizing double bubble(s) enclosing areas $A_1, A_2$ on the torus. If equality holds, the standard chain fits on the torus and is itself a minimizing double bubble on the torus.*

*Proof.* Consider a fundamental domain of the torus, a parallelogram with side lengths 1 and $L$ and with interior angle $\alpha \in [\pi/3, \pi/2]$. We orient the parallelogram so that the side with length 1 is vertical. Also, let $R_1$ be a component of higher (or equal) pressure enclosed in the chain, and let $R_2$ be the other component enclosed in the chain. For $i = 1, 2, 3$ define $C_i$ and $\theta_i$ as in the first paragraph of the proof of Proposition 7.2.1.

We immerse the chain in the torus, such that the chain and the side of length 1 have the same homology. It suffices to prove that if the chain is not embedded, then it has more perimeter than some (embedded) minimizer enclosing areas $A_1, A_2$ on the torus. Because the chain is not embedded in the torus, it does not only wrap around the torus in the direction of the side with length 1; it also wraps around the torus in the direction of the side with length $L$. We consider two cases: first, where the chain wraps around to intersect itself because the two components intersect each other; second, where instead at least one component intersects itself but not the other component.

First suppose that both components of the chain intersect each other. For $i = 1, 2$, consider either boundary arc of $R_i$ that lies along the boundary of the chain. The horizontal distance between the midpoint of this arc and the chord subtending it is $d_i = (C_i/2)\tan(\theta_i/2)$. Also, the vertices of the standard chain lie on two vertical closed geodesics, and the horizontal distance between these closed geodesics is $C_3$. Now, because the chain wraps around the torus in a nonvertical direction, the sum of $d_1$, $d_2$, and $C_3$ must exceed the horizontal distance $L\sin\alpha$ between the two vertical sides of the parallelogram. Hence,

$$\frac{C_1}{2}\tan\left(\frac{\theta_1}{2}\right) + \frac{C_2}{2}\tan\left(\frac{\theta_2}{2}\right) + C_3 > L\sin\alpha \geq \sin(\pi/3) = \frac{\sqrt{3}}{2}.$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

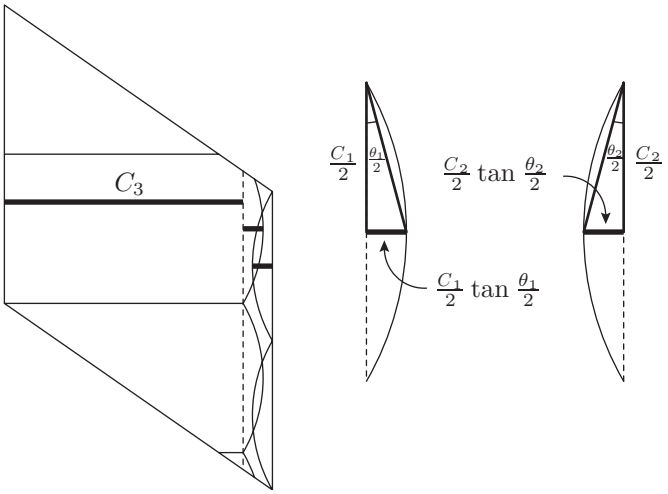

FIGURE 32. One way a standard chain might be nonembedded is if the two components intersect each other. In this case, by considering three segments perpendicular to the short direction with total length at least $\sqrt{3}/2$, it can be shown that the arcs separating the two components in the chain are long enough (greater than .5) to prove that the chain does not have minimizing perimeter.

From our parameterization, $C_1 + C_2 = 1$ and $\theta_2 < \theta_1 < \pi/3$. Therefore,

$$\frac{C_1}{2}\tan\left(\frac{\theta_1}{2}\right) + \frac{C_2}{2}\tan\left(\frac{\theta_2}{2}\right) < \frac{C_1}{2}\tan\left(\frac{\pi}{6}\right) + \frac{C_2}{2}\tan\left(\frac{\pi}{6}\right) = \frac{1}{2}\tan\left(\frac{\pi}{6}\right) = \frac{\sqrt{3}}{6}.$$

Combining these two inequalities, we find that

$$C_3 > \frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{6} = \frac{\sqrt{3}}{3} > \frac{1}{2}.$$

Hence, each of the arcs separating the two components enclosed in the chain has length greater than $\frac{1}{2}$. It easily follows that the perimeter of the chain is greater than 3. Therefore, by the perimeter bound (Proposition 3.8), the standard chain has perimeter greater than that of the (embedded) minimizer(s) enclosing the same areas.

Next suppose that one of the components — say, $R_i$ — intersects itself but not the other component. The area enclosed by $R_i$ on the torus thus forms a band wrapping around the torus in a nonvertical direction; let $\mathcal{B}_1$ be the boundary of this band. Also, let $\mathcal{B}_2$ be the boundary of a second band containing the two components of the chain (and excluding any area that lies in the overlap of the immersed chain). By Lemma 5.4.21, either the length of $\mathcal{B}_1 \cup \mathcal{B}_2$ is greater than 3, or the length of $\mathcal{B}_1 \cap \mathcal{B}_2$ is greater than or equal to 2.

If the length of $\mathcal{B}_1 \cup \mathcal{B}_2$ is greater than 3, then by the perimeter bound (Proposition 3.8), the perimeter of the standard chain has perimeter greater than that of the (embedded) minimizer(s) enclosing the same areas.

If instead the length of $\mathcal{B}_1 \cap \mathcal{B}_2$ is greater than or equal to 2, then let $R_j$ be the region in the chain different from $R_i$, and let $A_j$ be the area of this region. Then

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

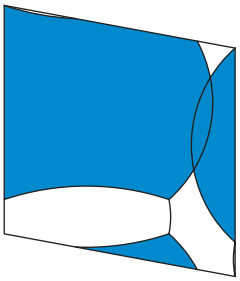

FIGURE 33. A second way a standard chain might be nonembedded is if at least one component intersects itself. The component then forms a band wrapping around the torus, implying (as was the case for octagon-square tilings) that the chain has a large perimeter.

$\mathcal{B}_1 \cap \mathcal{B}_2$ does not intersect the boundary of $R_j$. By the isoperimetric inequality for the plane, the perimeter of the region is at least $2\sqrt{\pi A_j}$. Therefore, the perimeter of the standard chain is at least $2 + 2\sqrt{\pi A_j}$. By Corollary 5.4.15, this exceeds the perimeter of the minimizer(s) enclosing the same areas. □

7.3. **Formulas for the band lens.** By Lemma 5.3.6, any minimizing band lens has the same homology as a shortest closed geodesic. Proposition 7.3.1 gives area and perimeter formulas for these band lenses.

**Proposition 7.3.1.** *Consider a band lens with the same homology as a shortest closed geodesic. Let* $r = (1/\text{curvature})$ *be the radius of curvature of the lens, and let* $d$ *be the width of the band. The area and perimeter formulas for the band lens in terms of* $r$ *and* $d$ *are*

$$\begin{aligned} A_{\text{Lens}}(r) &= 2r^2\left(\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right), \\ A_{\text{Band}}(r,d) &= d - r^2\left(\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right), \\ P(r) &= \left(\frac{4\pi}{3} - \sqrt{3}\right) r + 2. \end{aligned}$$

*Furthermore,* $r < \frac{1}{\sqrt{3}}$ *and* $d > \frac{r}{2}$.

*Proof.* The chord between the vertices of the lens, with length $C = 2r\sin(\pi/3) = \sqrt{3}r$, must fit along a short direction of the torus. Hence, $r < \frac{1}{\sqrt{3}}$. Also, because the band and lens do not overlap, the width of the band is greater than half the width of the lens. Hence, $d > r/2$.

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

Using (7.1)–(7.2), we can compute the area and perimeter formulas:

$$\begin{aligned} A_{\text{Lens}}(r) &= 2A\left(\frac{\pi}{3}, \sqrt{3}r\right) = 2r^2\left(\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right), \\ A_{\text{Band}}(r,d) &= d - \frac{1}{2}A_{\text{Lens}}(r) = d - r^2\left(\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right), \\ P(r) &= 2L\left(\frac{\pi}{3}, \sqrt{3}r\right) + (2 - \sqrt{3}r) = \left(\frac{4\pi}{3} - \sqrt{3}\right)r + 2. \end{aligned}$$

□

7.4. **Formulas for the standard hexagon tiling.** Corollary 5.4.12 showed that the perimeter of every standard hexagon tiling is equal to three. This section gives area formulas for the standard hexagon tiling (Proposition 7.4.1), proves that at most one standard hexagon tiling encloses two given areas (Lemma 7.4.2), and describes exactly which pairs of areas can be enclosed by a standard hexagon tiling (Lemma 7.4.4).

**Proposition 7.4.1.** *In any standard hexagon tiling, there exist $a, b, c$ with sum 1 such that one region $R_1$ is a hexagon with side lengths alternating between $a$ and $b$, another region $R_2$ is a hexagon with side lengths alternating between $b$ and $c$, and the exterior region $R_0$ is a hexagon with side lengths alternating between $c$ and $a$. Conversely, given positive $a, b, c$ with sum 1, there exists a corresponding standard hexagon tiling.*

*The areas of the three regions are*

$$\begin{aligned} A_{R_1} &= \frac{\sqrt{3}}{4}(a^2 + 4ab + b^2), \\ A_{R_2} &= \frac{\sqrt{3}}{4}(b^2 + 4bc + c^2), \\ A_{R_0} &= \frac{\sqrt{3}}{4}(c^2 + 4ca + a^2). \end{aligned}$$

*Proof.* Consider the closed curve formed by the four segments $p, q, r, s$ depicted in Figure 34(a). Segments $p$ and $r$ are parallel to a short direction of the torus, and the segment $\sigma$ connecting the endpoints of the curve is parallel to the same short direction of the torus. Therefore, the segments $q$ and $s$ must veer the same distance away from $\sigma$. Because they both meet $\sigma$ at $2\pi/3$, they have equal length.

Just as $q$ and $s$ must be congruent, *any* two sides of a hexagon must be congruent if they are separated by one other side. It follows that the sides of the hexagons have one of three lengths $a, b, c$, as depicted in Figure 34(b). By Corollary 5.4.12, the tiling has perimeter three, implying that $a + b + c = 1$. Conversely, given any positive $a, b, c$ such that $a+b+c = 1$, one can construct the corresponding standard hexagon tiling as in Figure 34(b).

To find the area of $R_1$, extend the sides of $R_1$ with length $a$, as in Figure 35, in order to form an equilateral triangle with sides of length $a+2b$. The new equilateral triangle consists of $R_1$ and three small equilateral triangles with sides of length $b$. Therefore, the area of $R_1$ equals

$$\frac{\sqrt{3}}{4}(a+2b)^2 - 3 \cdot \frac{\sqrt{3}}{4}b^2 = \frac{\sqrt{3}}{4}(a^2 + 4ab + b^2).$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

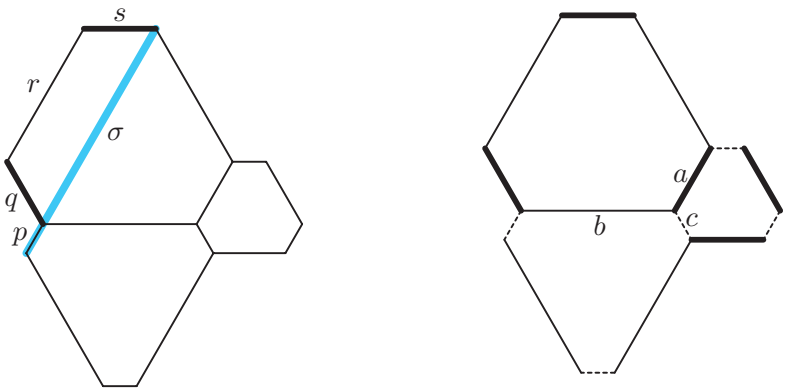

FIGURE 34. By examining how far various edges of a standard hexagon tiling veer from shortest closed geodesics, one can show that the sides of each hexagon alternate between two different lengths.

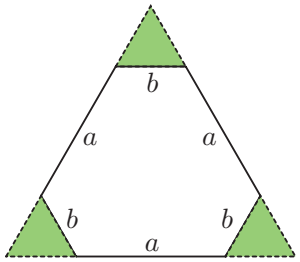

FIGURE 35. If the side lengths of a hexagon with interior angles of $2\pi/3$ alternate between two lengths, one can calculate the area of the hexagon by extending three sides to form an equilateral triangle.

We find the analogous formulas for the areas of $R_2$ and $R_0$ in a similar manner. □

**Lemma 7.4.2.** *Given positive real numbers $A_0, A_1, A_2$, there exists at most one triple $(a, b, c)$ of nonnegative numbers with sum 1 such that*

$$\begin{aligned} A_1 &= \frac{\sqrt{3}}{4}(a^2 + 4ab + b^2), \\ A_2 &= \frac{\sqrt{3}}{4}(b^2 + 4bc + c^2), \\ A_0 &= \frac{\sqrt{3}}{4}(c^2 + 4ca + a^2). \end{aligned}$$

*Proof.* Suppose, for sake of contradiction, that there existed two such triples $(a_1, b_1, c_1)$ and $(a_2, b_2, c_2)$. Without loss of generality, assume that $a_1 < a_2$. Because $a_1^2 + 4a_1b_1 + b_1^2 = a_2^2 + 4a_2b_2 + b_2^2$, it follows that $b_1 > b_2$. Similarly, because

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

$b_1^2 + 4b_1c_1 + c_1^2 = b_2^2 + 4b_2c_2 + c_2^2$, it follows that $c_1 < c_2$. Likewise, $c_1 < c_2$ implies that $a_1 > a_2$, a contradiction. □

**Corollary 7.4.3.** *Given prescribed areas $A_1, A_2$, there exists at most one standard hexagon tiling enclosing those areas.*

*Proof.* The result follows from our parameterization (Proposition 7.4.1) and Lemma 7.4.2. □

**Lemma 7.4.4.** *Given positive areas $A_0, A_1, A_2$ with sum $\sqrt{3}/2$ (the area of the hexagonal torus), there exists a standard hexagon tiling enclosing any two of those areas if and only if $\frac{2}{\sqrt[4]{3}}\left(\sqrt{A_j} + \sqrt{A_k}\right) > 1$ for $0 \le j < k \le 2$. That is, if and only if the side length of an equilateral triangle with area $A_j$ and the side length of an equilateral triangle with area $A_k$ have a sum greater than 1. (When equality holds for some pair, say $A_1, A_2$, a degenerate hexagon tiling exists, consisting of two equilateral triangles enclosing areas $A_1, A_2$ and with an exterior hexagonal region of area $A_0$.)*

*Proof.* Consider the following map from $\{(a, b) \mid 0 \le a, b \text{ and } a + b \le 1\}$ to $\mathbb{R}^2$:

$$(a, b) \mapsto \left( \frac{\sqrt{3}}{4}(a^2 + 4ab + b^2), \frac{\sqrt{3}}{4}(b^2 + 4b(1 - a - b) + (1 - a - b)^2) \right).$$

By our parameterization (Proposition 7.4.1), this map sends a pair of side lengths of a hexagon tiling to the areas of the region with side lengths $a, b$ and of the region with side lengths $b, 1 - a - b$. Thus, as we vary $a$ and $b$, we obtain all ordered pairs of areas that can be enclosed by a standard hexagon tiling.

By Lemma 7.4.2, the above map is injective. Also, it maps the boundary of its domain continuously to a simple closed curve $\mathcal{C}$ in $\mathbb{R}^2$, as depicted in Figure 36(a). (The figure is drawn with barycentric coordinates, not Cartesian coordinates.) Because the map is injective and continuous, it follows that its range is precisely the closed region bounded by $\mathcal{C}$. This boundary $\mathcal{C}$ consists of three pieces, corresponding to $a = 0, b = 0, c = 0$. When $a = 0$, we have $1 = b + c = \frac{2}{\sqrt[4]{3}}(\sqrt{A_1} + \sqrt{A_0})$; similarly, along the other two pieces of the boundary, we have $1 = \frac{2}{\sqrt[4]{3}}(\sqrt{A_j} + \sqrt{A_k})$ for $(j, k) = (1, 2)$ and $(0, 2)$. Hence, the interior of the region bounded by these three pieces consists of those area triples $(A_0, A_1, A_2)$ such that $\frac{2}{\sqrt[4]{3}}(\sqrt{A_j} + \sqrt{A_k}) > 1$ for $0 \le j < k \le 2$. Therefore, for each of these triples and no others, some standard hexagon tiling encloses some two of the three areas. □

**Lemma 7.4.5.** *If a minimizing double bubble enclosing areas $A_1, A_2$ on the hexagonal torus has perimeter equal to three, then there exists a (perimeter-minimizing) standard hexagon tiling enclosing those areas.*

*Proof.* Let the exterior region of the given double bubble have area $A_0$, and without loss of generality assume that $A_1 \le A_2 \le A_0$. By Lemma 5.4.14,

$$2 + \sqrt{A_1\left(\frac{8\pi}{3} - 2\sqrt{3}\right)}$$

is greater than or equal to the given minimal perimeter, three. The (nonsharp) bound $A_1 \ge \frac{4}{25}$ follows easily. Hence, $A_0 \ge A_2 \ge A_1 \ge \frac{4}{25}$. For $0 \le j < k \le 2$, we

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

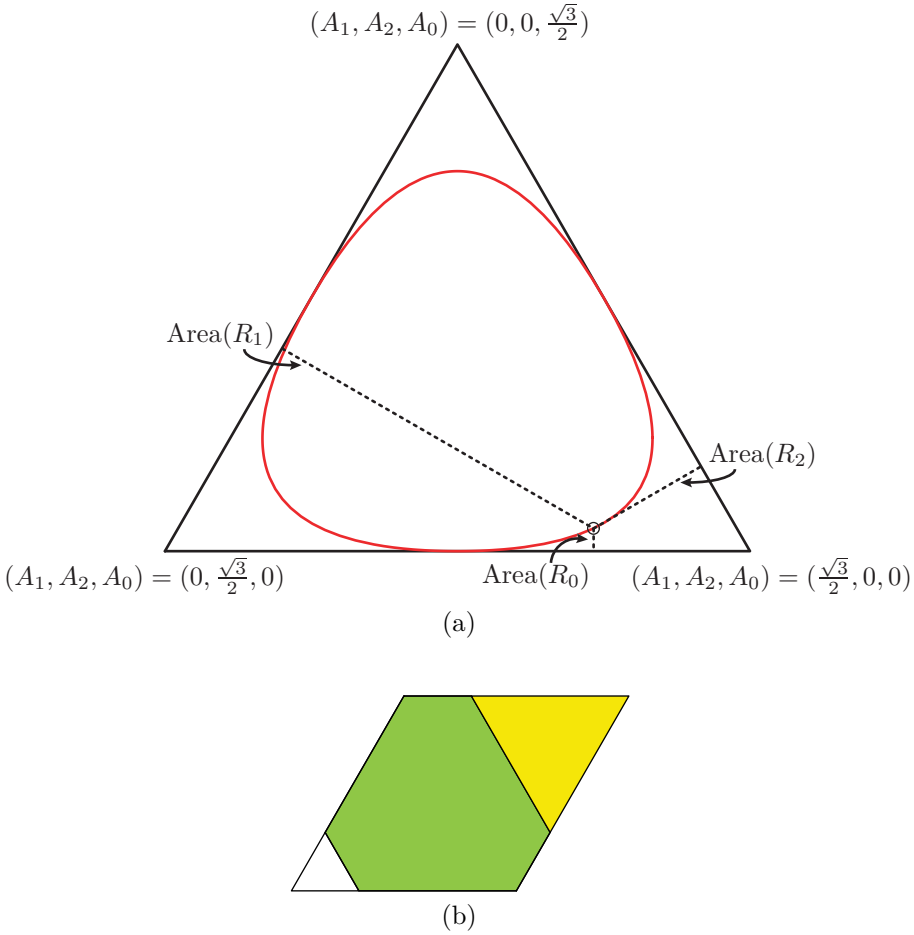

FIGURE 36. As in the phase portraits in Figure 2, the triangle in (a) represents the possible area pairs $(A_1, A_2)$ on the hexagonal torus, where the areas of the three regions are given by the distances to the three sides. The region bounded by the curve represents exactly those area pairs enclosed by some standard hexagon tiling. The curve itself represents area pairs enclosed by degenerate hexagon tilings consisting of a hexagon and two triangles, such as the one depicted in (b).

thus have

$$\sqrt{A_j} + \sqrt{A_k} \geq \frac{4}{5} \geq \frac{\sqrt[4]{3}}{2}.$$

By Lemma 7.4.4, there exists a standard hexagon tiling enclosing areas $A_1, A_2$. By Corollary 5.4.12, the tiling has perimeter three, so it is perimeter minimizing. □

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

## 8. Phase portraits

The phase portraits of Figure 2 show which of the minimizers of Theorem 6.1 win for which pairs of prescribed areas on four different tori — where we represent each torus as a parallelogram with side lengths $1, L$ and interior angle $\theta$. To create these phase portraits, we plot perimeter as a function of area pairs for each candidate in Theorem 6.1 using the parameterizations from Section 7. For each candidate in Theorem 6.1 besides the standard chain, we know that at most one double bubble exists enclosing any given pair of areas, so we can solve for its perimeter numerically. Because we do not know that at most one standard chain (of a fixed homology) exists enclosing two given areas, we instead create the perimeter-areas plot for the standard chain parametrically. Also, using Lemma 4.2, it is possible to show that any minimizing standard chain has axis-length 1, $L$, or $\sqrt{1 + L^2 \pm 2\angle \cos\theta}$, so we do not plot perimeter as a function of area pairs for other types of standard chains.

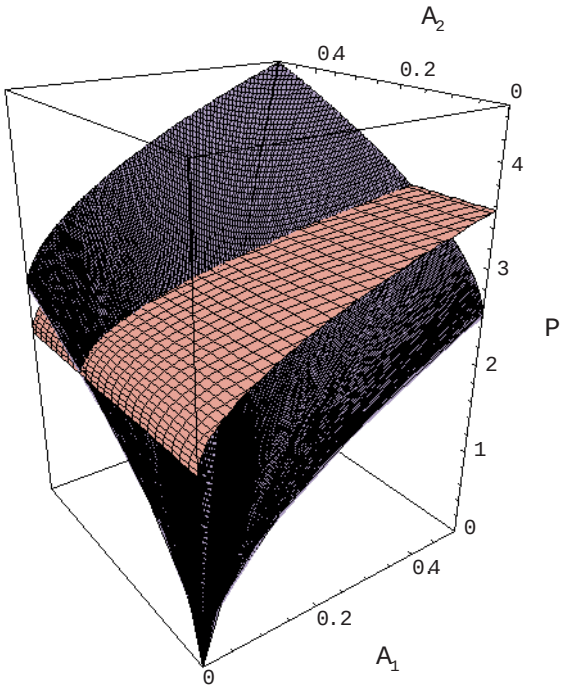

FIGURE 37. This *Mathematica* plot of the intersection of the perimeter plots for the standard double bubble and band lens illustrates the process used to create the phase portraits in Figure 2. The plots suggest that perimeters do not fluctuate wildly along certain sets of unusual area pairs, increasing our confidence that the phase portraits are accurate.

After plotting all these perimeter-areas plots simultaneously, we then view the combined plot from below so that at each area pair the plot(s) of the minimal calculated perimeter is visible. Figure 37 illustrates a simplified version of this

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

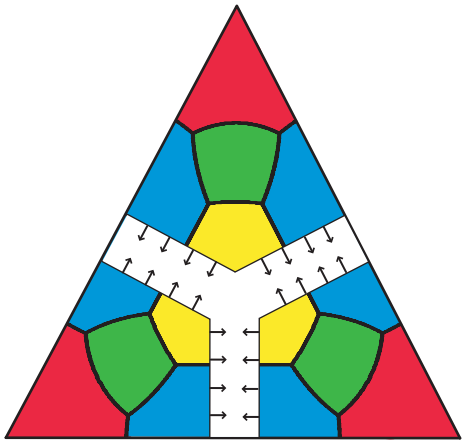

FIGURE 38. Removing pieces of this phase portrait for a rectangular torus with length 1.2 yields the phase portrait plot for some torus with less area.

process, comparing the perimeters of only two candidates, the standard double bubble and the band lens.

This process works if whenever the perimeter calculated for a given double bubble is minimizing for two given areas, the double bubble actually exists on the torus for those areas. Indeed, this is the case. When the standard double bubble does not fit on the torus, it has diameter greater than 1, so by Propositions 5.1.1 and 3.8 it cannot have minimizing perimeter. Lemma 5.4.14 shows that when the calculated perimeter for the band lens is minimizing, that band lens exists. By Lemma 7.2.4, when a standard chain with axis-length one has minimizing perimeter, it can be embedded on the torus; and according to the plots, no standard chain with axis-length greater than one has minimizing perimeter. As the simplest case, we know that the double band exists for all area pairs. Finally, by Lemma 7.4.5, when the minimal perimeter on the hexagonal torus is 3 for two given areas, there exists a standard hexagon tiling enclosing those two areas.

The following conjecture describes a simple connection *among* the various phase portraits. As usual, we assume that the shortest geodesics on the torus and the cylinder have unit length.

**Conjecture 8.1.** *Given areas $A_0 \geq A_2 \geq A_1$ and a torus with area $A_0 + A_1 + A_2$, the nontiling minimizing double bubble(s) enclosing $A_1, A_2$ on this torus are the same as the minimizing double bubble(s) enclosing $A_1, A_2$ on the infinite cylinder. Consequently the phase portrait of any flat two-torus can be obtained from the phase portrait of any flat two-torus of larger area (or from the phase portrait of the infinite cylinder) as in Figure 38. In particular, tori of equal areas have identical phase portraits.*

To prove Conjecture 8.1 it would suffice to show that every minimizing standard chain has axis-length one. The proof would also use the fact (which we can show using Theorem 6.1) that in a minimizer, a region of greater pressure has no more

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use

area than a region of less pressure, as well as Proposition 5.1.1, Lemma 5.3.6, and Lemma 7.2.4.

## Acknowledgements

This is work of the Williams College National Science Foundation "SMALL" undergraduate research Geometry Group, advised by Frank Morgan. The authors would first like to thank Professor Morgan, whose patient advising and perseverance have managed to always keep us moving in the right direction. We also owe our thanks to the National Science Foundation and to Williams College for sponsoring the SMALL REU. In addition, we would like very much to thank Joel Hass and David Hoffman, organizers of the Clay/MSRI Summer School on the Global Theory of Minimal Surfaces, as well as MSRI and the Clay Institute for bravely supporting four of the authors during what happily turned out to be several very productive weeks in Berkeley in July, 2001. We are very grateful to Gary Lawlor, who came up with the idea for showing that octagon-square tilings are not minimizers. We would also like to thank John Sullivan and Michael Hutchings for helpful conversations about tilings on the torus and Wacharin Wichiramala for helping us understand quadrilaterals and area-preserving variations in hexagon tilings. Joseph Masters [Ma1] made the first stab at this problem, and we were grateful for his notes.

We present a conjecture, based on computational results, on the area-minimizing method of enclosing and separating two arbitrary volumes in the flat cubic three-torus, $\mathbf{T}^3$. For comparable small volumes, we prove that the standard double bubble from $\mathbf{R}^3$ is area-minimizing.

## 1. INTRODUCTION

The classical isoperimetric problem seeks the least-area way to enclose a single region of prescribed volume. About 200 BC, Zenodorus argued that a circle is the least-perimeter enclosure of prescribed area in the plane (see [Heath 60]). In 1884, Schwarz [Schwarz 1884] proved by symmetrization that a sphere minimizes surface area for a given volume in $\mathbf{R}^3$. Isoperimetric problems arise naturally in many parts of modern mathematics; Ros provides a nice survey [Ros 01].

The double bubble problem is a two-volume generalization of the classical isoperimetric problem. In 2000, Hutchings, Morgan, Ritoré, and Ros proved that the standard double bubble was the unique least-area way to enclose and separate two volumes in $\mathbf{R}^3$ ([Hutchings et al. 00], [Hutchings et al. 02], [Morgan 00, Chapter 14]). In this paper, we present a conjecture, based on substantial numerical evidence, on the least-area way to enclose and separate two volumes in the three-torus.

**Conjecture 1.1. (Central Conjecture 2.1.)** *The ten different types of two-volume enclosures pictured in Figure 1 comprise the complete set of surface area-minimizing double bubbles for the flat cubic three-torus* $\mathbf{T}^3$.

The numerical results summarized in Figure 2 indicate the volumes for which we conjecture each type of double bubble minimizes surface area.

In Section 4, we show that for two small comparable volumes, the standard double bubble from $\mathbf{R}^3$ is optimal in $\mathbf{T}^3$. Specifically, we prove the following theorem:

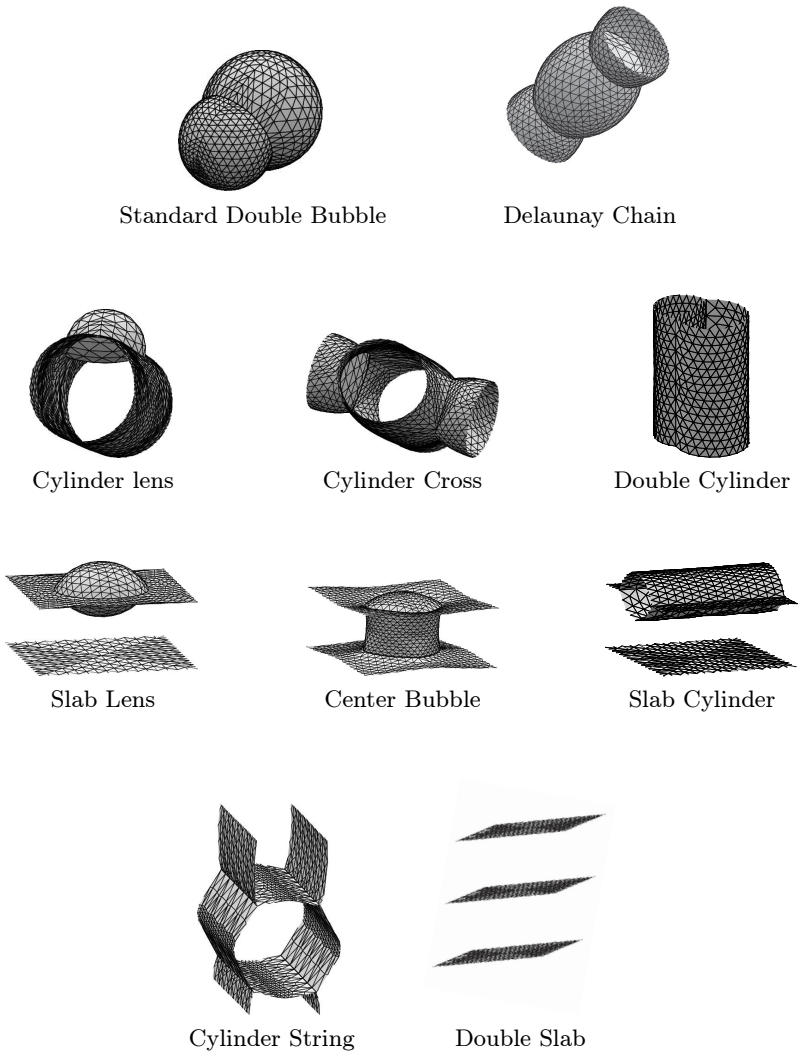

**FIGURE 1**. Catalog of conjectured minimizers.

**Theorem 1.2.** *Let $M$ be a flat Riemannian manifold of dimension three or four such that $M$ has compact quotient by its isometry group. Fix $\lambda \in (0, 1]$. Then there is an $\epsilon > 0$ such that, if $0 < v < \epsilon$, an area-minimizing double bubble in $M$ of volumes $v, \lambda v$ is standard.*

We conclude the paper with some extensions to the primary conjecture that address noncubic tori and additional volume constraints.

### 1.1 Existence and Regularity

Using the language of geometric measure theory, bubble clusters can be expressed as rectifiable currents, varifolds, or $(\mathbf{M}, \epsilon, \delta)$-minimal sets [Morgan 00]. In three dimensions, area-minimizing bubble clusters exist and consist of constant-mean-curvature surfaces meeting smoothly in threes at 120° along smooth curves, which meet in fours at a fixed angle of approximately 109° ([Taylor 76, Theorems II.4, IV.5, IV.8], or [Morgan 00, Section 13.9]).

### 1.2 Recent Results

In 2000, Hutchings, Morgan, Ritoré, and Ros announced a proof that the standard double bubble, the familiar shape consisting of three spherical caps meeting one another at 120-degree angles, provides the area-minimizing method of enclosing and separating two volumes in $\mathbf{R}^3$ ([Hutchings et al. 02], [Hutchings et al. 00]). The key features of the proof are a component bound developed by Hutchings [Hutchings 97, Theorem 4.2] and an insta-

bility argument. Reichardt et al. [Reichardt et al. 03] extended this result to $\mathbf{R}^4$.

In 2002, Corneli et al. [Corneli et al. 03] solved the double bubble problem for the flat two-torus, showing that there are five types of minimizers (one of which only occurs on the hexagonal torus). The proof relies on regularity, a variational component bound due to Wichiramala [Morgan and Wichiramala 02], and combinatorial and geometric classification.

### 1.3 Single Bubbles in $\mathbf{T}^3$

Even the single bubble for the three-torus is not yet completely understood. There are, however, partial results. The smallest enclosure of half of the volume of the torus was shown by Barthe and Maurey [Barthe and Maurey 00, Section 3] to be given by two parallel two-tori. Morgan and Johnson [Morgan and Johnson 00, Theorem 4.4] showed that the least-area enclosure of a small volume is a sphere. Spheres, tubes around geodesics, and pairs of parallel two-tori are shown to be the only types of area-minimizing enclosures for most three-tori by work of Ritoré and Ros ([Ritoré 97, Theorem 4.2], [Ritoré and Ros 96]).

### 1.4 Small Comparable Volumes

We prove Theorem 4.1 by showing that every sequence of area-minimizing double bubbles with decreasing volume and fixed volume ratio contains standard double bubbles. The main difficulty lies in bounding the curvature. Once this is accomplished, it is possible to show that the bubble lies inside a small ball that lifts to $\mathbf{R}^3$, where by [Hutchings et al. 02], a minimizer is known to be standard.

The main idea of the argument is as follows: From a given sequence of double bubbles with shrinking volumes and fixed volume ratio, we generate a new sequence by rescaling the ambient manifold at each stage so that one of the volumes is always equal to one. We can then apply compactness arguments and area estimates to show that certain subsequences of sequences obtained by rigid motions of the ambient manifold have nontrivial limits. These limits are used to obtain a curvature bound on a subsequence. With such a bound, we apply a monotonicity result to conclude that for small volumes, the double bubble is contained in a small ball. We conclude that it must be the same as the minimizer in $\mathbf{R}^3$ or $\mathbf{R}^4$, i.e., it must be the standard double bubble by [Hutchings et al. 02] or [Reichardt et al. 03]. The result applies to any flat three- or four-manifold with compact quotient by the isometry group.

### 1.5 Plan of the Paper

Section 2 reviews the methods that led to our Central Conjecture 2.1 and to Figures 1 and 2. Section 3 surveys some sub-conjectures. Section 4 is the statement and proof of the main theorem on small volumes. Section 5 shifts from the cubic torus to other tori and discusses other conjectures and candidates, including a "Hexagonal Honeycomb."

## 2. THE CONJECTURE

### 2.1 Generating Candidates

Participants in the 2001 CMI/MSRI Summer School proposed many possibilities for double bubbles in the three-torus $\mathbf{T}^3$ in brainstorming sessions.

Standard Double Bubble. The least-area double bubble in $\mathbf{R}^3$.

Delaunay Chain. Two stacked "beads" or "drums" wrapping around one of the periods of the torus. The lateral surfaces are Delaunay surfaces (constant-mean-curvature surfaces of rotation).

Cylinder Lens. A cylinder wrapping around a period of the torus, with a small bubble attached.

Double Cylinder. Two cylinders wrapping around a period of the torus. Transverse sections by an orthogonal plane (i.e., a two-torus) are the standard double bubble in two dimensions. This is the first of a family of solutions we could describe as "cylinders over minimizing double bubbles in the two-torus."

Cylinder String. A cylinder over a "Symmetric Chain" in $\mathbf{T}^2$.

Slab Cylinder. Two parallel flat two-tori with a cylindrical bubble attached to one of them. This is a cylinder over a "Band Lens" in $\mathbf{T}^2$.

Double Slab. Three parallel flat two-tori (cylinder over a "Double Band" in $\mathbf{T}^2$).

Slab Lens. Two parallel flat two-tori, one of which has a small lens-shaped bubble stuck in it.

Center Bubble. Two close-to-parallel two-tori with a close-to-cylindrical bubble between them. The planes buckle slightly (as can be shown by elementary stability considerations) and the bubble stuck between them is not quite round (it bulges slightly in the direction of each of the four corners of the fundamental domain pictured in Figure 1).

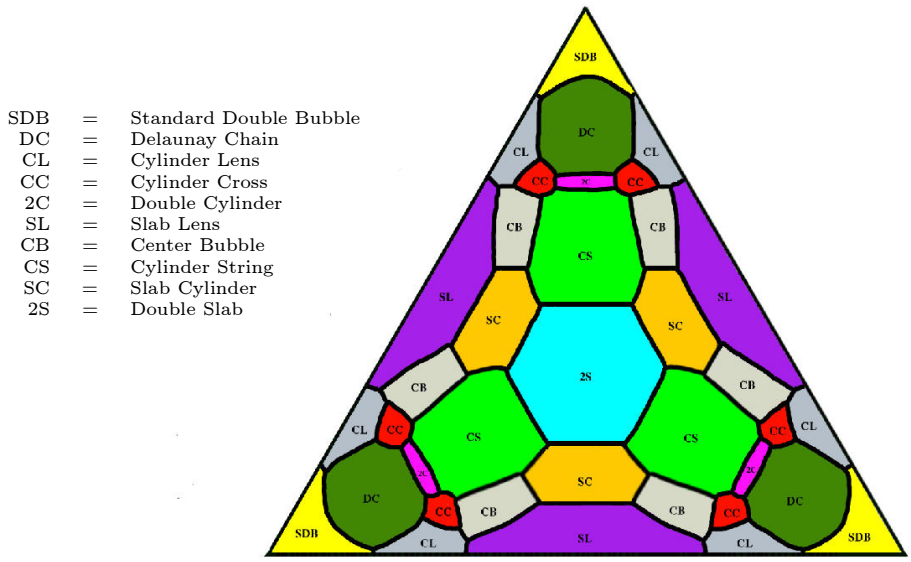

**FIGURE 2.** Phase portrait: volumes and corresponding double bubble. In the center both regions and the complement have one third of the total volume; along the edges, one volume is small; in the corners, two volumes are small.

Transverse Cylinders. Two cylinders wrapping around two different periods of the three-torus that touch each other to reduce surface area.

Hydrant Lens. The Schwarz $P$ surface with a small bubble attached.

Double Hydrant. Another fanciful proposal based on the Schwarz $P$ surface, known as "Scary Gary" after its inventor, Gary Lawlor.

Inner Tube. A cylinder that wraps around one of the periods of the three-torus with a toroidal bubble wrapped around it.

When preparing for the calculations that resulted in the phase diagram of Figure 2, we anticipated the possibility that a minimizing bubble topology might have been missed. In fact, two additional candidate topologies were found by systematic application of this heuristic:

> When the two volumes are very small, the standard double bubble should be optimal. As one or both of the two volumes grow, a bubble that collides with itself should open up to reduce perimeter, whereas if two different bubbles collide, they should stick.

This procedure incorporates the assumption that all three regions associated with a minimizer will be connected. The new candidates we found were as follows:

Cylinder Cross. A cylinder wrapping around one period of the torus with an attached bubble that wraps around one of the perpendicular directions. (Obtained from the Cylinder Lens when the small region grows.)

Center Cylinder. Two parallel flat two-tori with a cylinder going through both of them and wrapping around a period of the three-torus. (Obtained from the Center Bubble when the small region grows or from the Transverse Cylinders as one of the cylinders grows.)

### 2.2 Producing the Phase Diagram

Brakke's *Surface Evolver* [Brakke 99] was used to closely approximate the minimal area that a double bubble of each type needs to enclose specified volumes. Our initial simulations were done with volume increments of 0.05 (from a total volume of 1) for the initial set of brainstormed candidates. The results of these calculations were sufficient to convince us that the Hydrant Lens and the Double Hydrant were inefficient and that the Inner Tube was in fact unstable (which is why we could not draw a picture of it with *Surface Evolver* for inclusion in

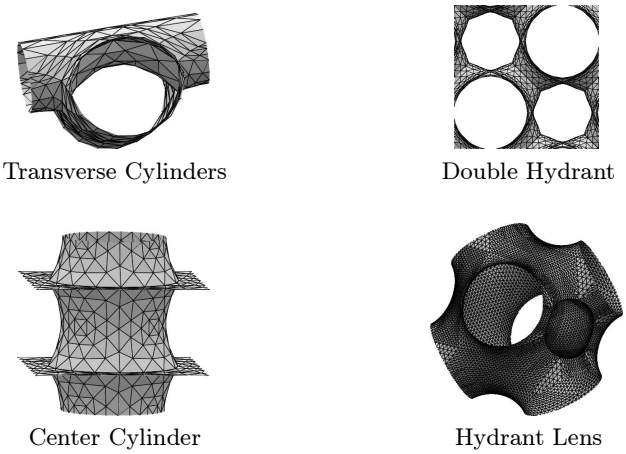

**FIGURE 3**. Inefficient double bubbles.

this paper). A rough version of Figure 2 was then obtained using a volume increment of 0.01. From the data obtained in these computations, we found that each of the double bubbles pictured in Figure 1 was the least-area competitor for some volume triple $v_1 : v_2 : v_3$. The phase diagram appearing in Figure 2 is the result of refining our second series of computations along the boundaries between the regions using a volume increment of 0.005.

**Conjecture 2.1. (Central Conjecture.)** *The ten double bubbles pictured in Figure 1 represent each type of surface area-minimizing two-volume enclosure in a flat, cubic three-torus, and these types are minimizing for the volumes illustrated in Figure 2.*

### 2.3 Comments

One might guess that minimizers would be formed from topological spheres and tori that go around at least one period of $\mathbf{T}^3$. This was borne out in our computations. It is interesting to note that although the Transverse Cylinders pictured in Figure 3 match this description, they were never seen to be minimizing.

A challenging problem related to the problem of area minimization is that of finding all of the stable double bubbles in $\mathbf{T}^3$; there are probably quite a few that we have not looked at. Note that a given type from Figure 1 might be stable for a much wider range of volumes than those for which it actually minimizes surface area.

It is worth observing that all of the conjectured minimizers for the double bubble problem on $\mathbf{T}^2$ are echoed here in at least two ways: several conjectured minimizers are $\mathbf{T}^2$ minimizers $\times$ $\mathbf{S}^1$, and others are more direct analogues, for example, the Delaunay and Symmetric Chains. See Corneli et al. [Corneli et al. 03] for more on the $\mathbf{T}^2$ minimizers.

A few words about the accuracy of the simulations are in order. The commands used in our final stage of numerics were as follows:

```
// five cycles of refining the mesh and
// decreasing area
{{u; g; u} 10; {u; r; u}} 5;
// decrease area ten more times at the end
{u; g; u} 10;
```

These commands produced pictorial output that perfectly matches our idea of what each conjectured minimizer should look like.

## 3. SUBCONJECTURES

We now present a list of natural subconjectures about bubbles in the flat cubic three-torus $\mathbf{T}^3$ that are suggested either by the phase diagram or by examination of the pictures made by *Surface Evolver*.

One immediate observation is that the edges of our phase diagram appear to characterize single bubbles in $\mathbf{T}^3$.

**Conjecture 3.1.** (Ritoré and Ros [Ritoré 97], [Ritoré and Ros 96],[Ros 01].) *The optima for the isoperimetric problem in* $\mathbf{T}^3$ *are the sphere, cylinder, and slab.*

The following two conjectures are perhaps the most intuitive things we would expect to be true about bubbles in $\mathbf{T}^3$:

**Conjecture 3.2.** *An area-minimizing double bubble in* $\mathbf{T}^3$ *has connected regions and complement.*

**Conjecture 3.3.** *There is an* $\epsilon > 0$ *such that if* $v_1, v_2$ *are both less than* $\epsilon$*, the standard double bubble of volumes* $v_1$ *and* $v_2$ *is optimal in* $\mathbf{T}^3$*.*

In Theorem 4.1, we prove that there is such an $\epsilon$ for every fixed ratio of volumes.

If it were known for some reason that the number of components of a minimizer was relatively small, then we think the next two conjectures might admit fairly easy proofs:

**Conjecture 3.4.** *For one very small volume and two moderate volumes, the Slab Lens is optimal.*

**Conjecture 3.5.** *The first phase transition as small equal or close to equal volumes grow is from the standard double bubble to a chain of two bubbles bounded by Delaunay surfaces.*

Delaunay surfaces are constant-mean-curvature surfaces of rotation, and as such contain an $\mathbf{S}^1$ in their symmetry group. From the *Surface Evolver* pictures, it appears that the conjectured surface area minimizers always have the maximal symmetry, given the constraints, a fact that leads to the following natural conjecture.

**Conjecture 3.6.** *All isotopies that are not isometries decrease a minimizer's symmetry group.*

We will conclude the section with a proposition that establishes a very limited symmetry property for all double bubbles in the two torus (including nonminimizing bubbles). Specifically, we prove that for any double bubble, there is a pair of parallel two-tori that cut both regions in half. Hutchings [Hutchings 97, Theorem 2.6] was able to show that in $\mathbf{R}^n$ a minimizing double bubble has two perpendicular planes that divide both regions in half. He used this result in the proof that the function that gives the least-area to enclose two given volumes in $\mathbf{R}^n$ is concave. We conjecture that a similar concavity result also holds for the three-torus:

**Conjecture 3.7.** *The least area to enclose and separate two given volumes in the three-torus is a concave function of the volumes.*

If one could prove Conjecture 3.7, one would then be able to apply other ideas in Hutchings' paper [Hutchings 97, Section 4] to obtain a functional bound on the number of components of a minimizing bubble.

**Proposition 3.8. (Deluxe Ham Sandwich Theorem.)*** *If a double bubble lies inside a solid two-torus inside a rectangular three-torus,* $D^2 \times \mathbf{S}^1 \subset \mathbf{S}^1 \times \mathbf{S}^1 \times \mathbf{S}^1$*, then there is a pair of parallel two-tori that divide both volumes in half.*

*Proof:* This is a generalization of the standard argument for the ham sandwich theorem in Euclidean space. We will regard the three-torus as the result of identifying the faces of a rectangular solid $[-n, n] \times [-m, m] \times [0, p]$ in $\mathbf{R}^3$. We may assume that the solid torus is a vertical cylinder with base centered at the origin in the $x - y$ plane. Now we rotate this solid cylinder, and index the rotation by $\alpha \in [0, 2\pi]$. Then for each $\alpha \in [0, \pi]$, rotate the cylinder (along with the surface that lies inside) by $\alpha$ in the $x - y$ plane and consider the family of pairs of planes $\{y = c, y = c + m\}$, where $c \in [-m, 0]$ For each $\alpha \in [0, \pi]$, there is at least one such pair of planes that cuts the volume $V_1$ in half, in the sense that half of $V_1$ is in the inside of the planes, and half of $V_1$ is on the outside of the two planes. There may be an interval of such pairs for a given $\alpha$. However, some one-parameter family of these planes may be chosen which varies continuously as a function of $\alpha$, and coincides at 0 and $\pi$. Since by the time $\alpha$ reaches $\pi$ the two portions of $V_2$ have switched sides, there must be some pair of planes that divides $V_2$ in half. The restriction of these planes to the domain $[-n, n] \times [-m, m] \times [0, p]$ glue up to a pair of two-tori in the three-torus that divides both regions in half. □

## 4. SMALL COMPARABLE VOLUMES

Conjecture 3.3 asserts that two small volumes in $\mathbf{T}^3$ are best enclosed by a standard double bubble. In this section, we will prove Theorem 4.1, which says that for any fixed volume ratio, the standard double becomes optimal when the volumes are sufficiently small. This result holds for a relatively broad class of three- and four-dimensional manifolds (and see Remark 4.4).

The standard double bubble consists of three spherical caps meeting at 120 degrees (see Figure 2). If the volumes are equal, the middle surface is planar. The standard double bubble is known to be minimizing for all volume pairs in $\mathbf{R}^3$ [Hutchings et al. 02] and $\mathbf{R}^4$ [Reichardt et al. 03].

*Name suggested by Eric Schoenfeld, who gave an independent proof for $\mathbf{T}^2$.

**Theorem 4.1.** *Let $M$ be a flat Riemannian manifold of dimension three or four such that $M$ has compact quotient by its isometry group. Fix $\lambda \in (0, 1]$. Then there is an $\epsilon > 0$ such that, if $0 < v < \epsilon$, an area-minimizing double bubble in $M$ of volumes $v, \lambda v$ is standard.*

**Remark 4.2.** Our assumption on the isometry group guarantees solutions to the double bubble problem for all volume pairs (the proof is the same as in Morgan [Morgan 00, Section 13.7]). Not every flat 3-manifold has compact quotient by its isometry group. Euclidean 3-space modulo a glide reflection or a glide rotation is an example.

It is helpful to have the overall strategy of the proof in mind before we go on. Our goal is to prove that a minimizing double bubble of volumes $v$, $\lambda v$ lies inside a trivial ball in $M$ when $v$ is small enough. The results for Euclidean space then prove our claim.

For the proof, we will regard a double bubble as a pair of three- or four-dimensional rectifiable currents, $R_1$ and $R_2$, each of multiplicity one, of volumes $V_1 = \mathbf{M}(R_1)$ and $V_2 = \mathbf{M}(R_2)$. The total area of such a double bubble is $\frac{1}{2}(\mathbf{M}(\partial R_1) + \mathbf{M}(\partial R_2) + \mathbf{M}(\partial(R_1 + R_2)))$. Here $\mathbf{M}$ denotes the mass of the current, which can be thought of as the Hausdorff measure of the associated rectifiable set (counting multiplicities). For a review of the pertinent definitions, see the notes from Morgan's course at the CMI/MSRI Summer School [Morgan and Ritoré 01] or the texts by Morgan [Morgan 00] or Federer [Federer 69]. By the Nash and subsequent isometric embedding theorems, we may assume $M$ is a submanifold of some fixed $\mathbf{R}^N$.

We will consider a sequence of area-minimizing double bubbles in $M$ enclosing the volumes $v$ and $\lambda v$, as $v \to 0$. If the theorem were false, there would be some such sequence with no standard double bubbles in it. We prove that every sequence of fixed volume ratio double bubbles with shrinking volumes contains standard double bubbles.

For each $v$, $M_v$ will denote $s_v(M)$ in $\mathbf{R}^N$, where $s_v$ is the scaling map that takes regions with volume $v$ to similar regions with volume 1. In particular, $s_v$ maps our area-minimizing double bubble enclosing volumes $v$ and $\lambda v$ to a double bubble which we call $S_v$ that encloses volumes 1 and $\lambda$, and is of course area-minimizing for these volumes.

The first step is to show that once $M_v$ has been suitably translated and rotated, the sequence $S_v$ has a subsequence that converges as $v \to 0$ with $V_1 \neq 0$ in the limit. Our argument also shows that there is a differently modified subsequence that converges to a limit with $V_2 \neq 0$, but does not show that there is a subsequence where both volumes are nonzero in the limit. This is because while we are exerting ourselves trapping the first volume in a ball, the second one may wander off to infinity.

The second step in the proof is to use these limits to obtain a weak bound on the curvature of a subsequence of $S_v$. We need this in order to apply the monotonicity theorem for mass ratio [Allard 72, Section 5.1(1)], which says that a small ball around any point on a surface with weakly bounded mean curvature contains some substantial amount of area.

The third step is to show that all of the surface area of each element of our subsequence is contained in some ball in $M_v$ that has fixed radius for all $v$. Eventually, as $v$ shrinks and $M_v$ grows, this ball will have to be trivial in $M_v$.

We then use the result that the optimal double bubble in $\mathbf{R}^3$ is standard to show that our subsequence has a tail comprised of standard double bubbles. The desired conclusion then follows from the fact that $S_v$ is simply a scaled version of the original double bubble containing volumes $v$ and $\lambda v$. Thus there is no sequence of shrinking fixed-ratio area-minimizing double bubbles in $M$ that does not contain standard double bubbles.

We focus on the case of dimension three; the proof for dimension four is essentially identical.

The following lemma is needed in the first step of the proof.

**Lemma 4.3.** *There is a $\gamma > 0$ such that if $R$ is a region in an open Euclidean 3-cube $K$ and $\mathrm{vol}(R) \leq \mathrm{vol}(K)/2$, then*

$$\mathrm{area}(\partial R) \geq \gamma(\mathrm{vol}(R))^{2/3}.$$

*Proof:* Let $\gamma_0$ be such an isoperimetric constant for a cubic three-torus, so that $\mathrm{area}(\partial P) \geq \gamma_0(\mathrm{vol}(P))^{2/3}$ for all regions $P \subseteq \mathbf{T}^3$. Such a $\gamma_0$ exists by the isoperimetric inequality for compact manifolds [Morgan 00, Section 12.3]. Make the necessary reflections and identifications of the cube $K$ to obtain a torus containing a region $R'$ with eight times the volume and eight times the surface area of $R$. The claim follows, with $\gamma = \gamma_0/2$. □

*Proof of Theorem 4.1:*

*Step 1. The sequence $S_v \subset M_v$, where each $M_v$ has been suitably translated and rotated, has a subsequence that converges with $V_1 \neq 0$ in the limit.*

We first show the existence of a covering $\mathcal{K}_v$ of $M_v$ with bounded multiplicity, consisting of 3-cubes contained in $M_v$, each of side-length $L$, for any $L > 0$. Lemma 4.3 will give us a positive lower bound on the volume of the part of $R_1$ that is inside one of these cubes for each $S_v$. We will then apply a standard compactness theorem to show that a subsequence of the sequence of $S_v$ converges.

Take a maximal packing of $M_v$ by balls of radius $\frac{1}{4}L$. Enlargements of radius $\frac{1}{2}L$ cover $M_v$. Circumscribed 3-cubes in $M_v$ of edge-length $L$ provide the desired covering $\mathcal{K}_v$. To see that the multiplicity of this covering is bounded, consider a point $p \in M_v$. The ball centered at $p$ with radius $2L$ contains all the cubes that might cover it, and the number of balls of radius $\frac{1}{4}L$ that can pack into this ball is bounded, implying that the multiplicity of $\mathcal{K}_v$ is also bounded by some $m > 0$.

Now let $\mathcal{K}_v$ be a covering as above, with $L = 2$. By Lemma 4.3, there is an isoperimetric constant $\gamma$ such that

$$\text{area}(\partial(R_1 \cap K_i)) \geq \gamma(\text{vol}(R_1 \cap K_i))^{2/3},$$

and therefore, since $\max_k \text{vol}(R_1 \cap K_k) \geq \text{vol}(R_1 \cap K_i)$ for any $i$,

$$\text{area}(\partial(R_1 \cap K_i)) \geq \gamma \frac{\text{vol}(R_1 \cap K_i)}{(\max_k \text{vol}(R_1 \cap K_k))^{1/3}}. \quad (4\text{–}1)$$

Note that the total area of the surface is greater than $1/m$ times the sum of the areas in each cube, and the total volume enclosed is less than the sum of the volumes, so summing Equation 4–1 over all the cubes $K_i$ in the covering $\mathcal{K}_v$ yields

$$\text{area}(S_v) \geq \text{area}(\partial R_1) \geq m\gamma \frac{V_1}{(\max_k \text{vol}(R_1 \cap K_k))^{1/3}}$$

and

$$(\max_k(\text{vol}(R_1 \cap K_k)))^{1/3} \geq m\gamma \frac{V_1}{\text{area}(S_v)} \geq \delta,$$

for some $\delta > 0$, because $V_1 = 1$ and $\text{area}(S_v)$ is bounded (there is a bounded way of enclosing the volumes, and $S_v$ has the same amount of area or less).

Translate each $M_v$ so that a cube $K_k$ that maximizes $\text{vol}(R_1 \cap K_k)$ is centered at the origin of $\mathbf{R}^N$, and rotate so that the tangent space of each $M_v$ at the origin is equal to a fixed $\mathbf{R}^3$ in $\mathbf{R}^N$. The limit of the $M_v$ will be equal to this $\mathbf{R}^3$. Since a cube with edge-length $L$ centered at the origin fits inside a ball of radius $2L$ centered at the origin, we have

$$\text{vol}(R_1 \cap B(0, 2L)) \geq \delta^3$$

for every $S_v$. By the compactness theorem for locally integral currents ([Morgan 00, pp. 64, 88], [Simon 84, Section 27.3, 31.2, 31.3]), we know that a subsequence of the $S_v$ has a limit, which we will call $D$, with the property that $\text{vol}(R_1) \geq \delta^3$. This completes the first step.

Since $D$ is contained in the limit of the $M_v$, namely, the copy of $\mathbf{R}^3$ chosen above, and each $S_v$ is minimizing for its volumes, a standard argument shows that the limit $D$ is the area-minimizing way to enclose and separate the given volumes $\text{vol}(R_1) \geq \delta^3$ and $\text{vol}(R_2)$ in $\mathbf{R}^3$ (see [Morgan 00, 13.7]). In the limit, $\text{vol}(R_2)$ could be zero, in which case $D$ is a round sphere. If both volumes are nonzero, $D$ is the standard double bubble ([Hutchings et al. 02] and [Reichardt et al. 03], or see [Morgan 00, Chapter 14]).

*Step 2. By taking a subsequence if necessary, we may assume there is a weak bound on the curvature of the $S_v$.*

To show that the mean curvature is weakly bounded is to show that there is a $C$ such that for any $S_v$, and any direction in the two-dimensional space of possible volume changes, $|\frac{dA}{dV}| \leq C$ for smooth variations. Thus it suffices to produce smooth variations such that changes in the volume of $S_v$ and in the area of $\partial S_v$ are controlled, that is, that the magnitude of the change in volume is bounded from below and the magnitude of the change in area is bounded from above.

We first show that the magnitude of the change in volume is bounded below. Take a smooth variation vector field $F$ in $\mathbf{R}^n$ such that for $D$,

$$dV_1/dt = \int_{\partial R1} (F \cdot n)\, dA = c \neq 0$$

and

$$dV_2/dt = 0.$$

(Note that we need the first volume to be nonzero, or its variation could be zero.) For $v$ small enough, the subsequence of $S_v$ associated with the limit $D$ has the property that $dV_1/dt$ is approximately equal to the constant $c$ and $dV_2/dt$ is approximately equal to 0.

By the argument in the first step, we can translate and rotate each $M_v$ so that, after taking a subsequence again if necessary, $S_v$ converges to a minimizer $D'$ in $\mathbf{R}^3$ where the second volume is nontrivial. This time we take a smooth variation vector field $F'$, such that the images of $S_v$ under the appropriate rigid motions have the property that $dV_1/dt$ is approximately equal to 0 and $dV_2/dt$ is approximately equal to some constant $c' \neq 0$, for $v$ small enough.

Note that the change in volume is independent of rigid motions; in particular, we can translate both $F$ and $F'$

back along the rigid motions to act on $S_v$. This proves that for this sequence, the magnitude of the change in volume is bounded below.

Now we need to show that the change in area is bounded above. This follows from the fact that every rectifiable set can be thought of as a varifold [Morgan 00, Section 11.2]. By compactness for varifolds [Allard 72, Section 6], the $S_v$, situated so that the first volume does not disappear, converge as varifolds to some varifold, $J$. The first variations of the varifolds also converge, i.e., $\delta S_v \to \delta J$; see [Allard 72]. The first variation of a varifold is a function representing the change in area. Therefore, far enough out in the sequence the change in area of the $S_v$ under $F$ is bounded close to the change in area of $J$ under $F$, which is finite. Similarly, the change in area of the $S_v$ under $F'$ is bounded above.

We conclude that, after restricting to a subsequence, $S_v$ has the property that $|\frac{dA}{dV}|$ is bounded for two independent directions in the two-dimensional space of volume changes, and hence for the entire space. This completes the second step.

*Step 3. When $v$ is small, all of the elements of a subsequence of $S_v \subset M_v$ are contained in a ball with a fixed radius that can be lifted to* $\mathbf{R}^3$.

As $v$ shrinks, the area of each element of the subsequence $S_v$ found in Step 2 is bounded above by $A > 0$, since our double bubbles are area-minimizing, and a nearly Euclidean double bubble is one candidate. By monotonicity of mass ratio [Allard 72, Section 5.1(1)], every unit-radius ball centered at a point of $S_v$ contains at least area $\epsilon$, for some $\epsilon > 0$. Therefore, there are at most $A/\epsilon$ such disjoint balls.

We claim that the $S_v$ are eventually connected, which will imply that the diameter $S_v$ is bounded above by $2A/\epsilon$. Indeed, unless the $S_v$ are eventually connected, one can arrange to get in the limit a disconnected minimizer in $\mathbf{R}^3$ by translating and centering nontrivial volume on two different points. This is false, so we conclude that $S_v$ is contained in a ball of radius $2A/\epsilon$ for all small $v$.

Since our original manifold has compact quotient by its isometry group, we may quotient by isometries to get a compact 3-manifold. This implies that balls of a certain radius or smaller are topologically trivial. Hence, as we expand the manifold, balls of radius $2A/\epsilon$ can be lifted to $\mathbf{R}^3$, which means that they are Euclidean. This completes the third step.

Since $S_v$ is eventually contained in a Euclidean ball, the tail of this sequence is made up entirely of standard double bubbles ([Hutchings et al. 02], [Morgan 00, Chapter 14]). Recall that our sequence $S_v$ is simply a scaled version of the original sequence of minimizing double bubbles in $M$ enclosing volumes $v$ and $\lambda v$, where we have restricted to subsequences as necessary. Therefore, any sequence of area-minimizing double bubbles with shrinking volumes and fixed volume ratio contains standard double bubbles. We conclude that the minimizing double bubble with volume ratio $\lambda$ is standard when $v$ is small enough. □

**Remark 4.4.** Given $n$ and $m$, essentially the same argument shows that for any smooth $n$-dimensional Riemannian manifold with compact quotient by the isometry group, given $0 < \lambda \leq 1$, there are $C$, $\epsilon > 0$, such that for any $0 < v < \epsilon$, a minimizing cluster with $m$ prescribed volumes between $\lambda v$ and $v$ lies inside a trivial ball. For the case of flat three- or four-dimensional manifolds with compact quotient by the isometry group, this means that small clusters of bubbles with comparable volumes are the same as the Euclidean minimizer containing the same volumes. To deduce the corresponding result in the nonflat case would require knowing that convergence weakly and in measure, under bounded mean curvature, implies $C^1$ convergence, as is known for hypersurfaces without singularities ([Allard 72, Section 8], see [Morgan 01, Section 1.2]).

## 5. SPECIAL TORI

Changing the shape of the torus, by stretching it or by skewing some or all of its angles, would certainly change the phase diagram of Figure 2.

**Conjecture 5.1.** *In the special case of a very long three-torus, i.e., with side lengths $\{\frac{1}{\epsilon^2}, \epsilon, \epsilon\}$ $(\epsilon \to 0)$, the Double Slab is optimal for most volumes.*

Special tori may have special minimizers:

**Conjecture 5.2.** *For the special case of a torus based on a short hexagonal prism, the Hexagonal Honeycomb prism of Figure 4 is an area-minimizing double bubble when both regions and the exterior all have equal or close to equal volumes.*

Indeed, for such volumes, the Hexagonal Honeycomb ties the Double Slab, just as in the hexagonal two-torus, a Hexagonal Tiling ties the Double Band [Corneli et al. 03].

For multiple enclosed regions, we would expect to find minimizers that lift to $\mathbf{R}^3$ as periodic foams with cells of

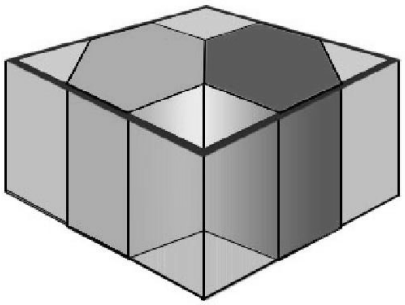

**FIGURE 4**. Hexagonal honeycomb

finite volume, such as Kelvin's foam or the Weaire-Phelan foam [Kusner and Sullivan 96].

However, there is no minimizing *double* bubble in any torus that lifts to a division of $\mathbf{R}^3$ into bounded regions. Indeed, as pointed out by Adams, Morgan, and Sullivan [Adams et al. 2003], by Lebesgue's Covering Theorem [Hurewicz and Wallman 41, Theorem IV2], such regions must sometimes meet in fours or more.

This suggests that it is likely that there are no other special minimizers for the double bubble problem.

**Conjecture 5.3.** *The double bubbles of Figure 1 together with the Hexagonal Honeycomb of Figure 4 comprise the complete set of area-minimizing double bubbles for all three-tori.*

In light of the fact that the triple bubble problem in the torus seems likely to produce many interesting candidates, we conclude with one final conjecture.

**Conjecture 5.4.** *For the triple bubble problem in a flat cubic three-torus in the case where one of the volumes is small, the minimizers will look like the double bubbles of Figure 2 with a small ball attached. The phase diagram will look just like our Figure 3.*

## ACKNOWLEDGMENTS

This paper was prepared on behalf of the participants in the Clay Mathematics Institute Summer School on the Global Theory of Minimal Surfaces, held at the Mathematical Sciences Research Institute in Berkeley, California, Summer 2001, and has its origins in a problem given there by Frank Morgan in his course, "Geometric Measure Theory and the Proof of the Double Bubble Conjecture." We are very grateful to Frank Morgan for taking the time to guide us through this project with many helpful discussions and constructive comments.

Thanks to CMI and MSRI for making the summer school possible, and for providing research and travel support to the authors. We extend our thanks to Joel Hass, David Hoffman, Arthur Jaffe, Antonio Ros, Harold Rosenberg, Richard Schoen, and Michael Wolf, who organized the summer school. We thank faculty participants Michael Dorff, Denise Halverson, and Gary Lawlor for help with the initial simulations, and Manuel Ritoré and John Sullivan for several helpful conversations. Other participants who made notable contributions include Baris Coskunuzer, Brian Dean, Dave Futer, Tom Fleming, Jim Hoffman, Jon Hofmann, Paul Holt, Matt Kudzin, Jesse Ratzkin, Eric Schoenfeld, and Jean Steiner.

Examining the results on $\mathbf{T}^2$ proved to be quite helpful to us in our work on the $\mathbf{T}^3$ project. We thank our colleagues from the SMALL Geometry Group for sharing their insights.

Yair Kagan of New College of Florida created the picture of the "Hexagonal Honeycomb" that appears in Figure 4. We thank him for this contribution.

We thank Ken Brakke for sharing his wonderful program, *Surface Evolver*, with the world and for answering questions about its use.

Joseph Corneli participated in the 2001 SMALL undergraduate summer research Geometry Group, supported by Williams College and by the National Science Foundation through an REU grant to Williams and an individual grant to Morgan. Genevieve Walsh was supported in part by NSF VIGRE Grant No. DMS-0135345.

# DOUBLE BUBBLES IN SPACES OF CONSTANT CURVATURE

BY
JOSEPH A. CORNELI

A Thesis

Submitted to the Division of Natural Sciences
New College of Florida,
in partial fulfillment of the requirements for the degree
of Bachelor of Arts
Under the sponsorship of Patrick T. McDonald

Sarasota, Florida
May, 2002

# Dedication

*To Bea Canchester and Helen Corneli, who encouraged me to pursue my education and have made significant material contributions that have made it possible.*

# Acknowledgements

My father's mother, to whom, together with my mother's mother, this thesis is jointly dedicated, told me at an early age that "it takes a village to raise a child". If this is true of my personal life (and it is) it is even more true of my academic life. This leaves me with many people to thank.

First of all there is my academic sponsor and thesis advisor, Pat McDonald. Pat taught me lots of math and has been very generous with both time and energy spent talking to me about my thesis, and about many other things. It is no coincidence that while I was his student I began to think seriously about how my mind works, to have solid hope for the future, to give respect where it is due and to value intellectual freedom. In short, Pat showed me what a mathematician is and opened the way for me to try it out for myself. In addition to all of this, he has a number of remarkable personal qualities, including his own special blend of modesty and confidence, that I have learned an immense amount by trying (and usually failing) to emmulate.

Then there is Frank Morgan of Williams College. Frank was my devoted advisor during a full year of research that lead to three and a half papers, that, in revised form, constitute the body of this thesis. While I was in his Geometry Group at Williams, Frank made daily comments on daily revisions of our papers every weekday morning (starting on our second day). Afterwards, he continued to advise me and my collaborators, mostly through an extensive email correspondence, in which he made hundreds of thoughtful suggestions about both research and writing. Working for Frank was always fun for me, in part because I was learning so much, but also because of his pleasant enthusiasm and congeniality. In addition to this, he arranged a number of special opportunities for the Geometry Group, including the unprecidented invitation of a group of undergraduates to the Mathematical Sciences Research Institute in Berkeley, California, and full participation in his special session on soap bubble geometry at MathFest'01 in Madison, Wisconsin. By observing Frank in action, I learned an immense amount about how to interact positively with people.

Without the hard work of these two men, both exemplary scholars and teachers, this thesis would not exist. In addition to making that acknowledgement, I want to take this moment to thank each of them for taking a friendly interest in my personal and moral development as well as in my academics.

In addition to being jointly responsible for the majority of the content of this thesis, my collaborators during this past year were both my peers and my teachers, and they formed an invaluable asset to my general education in mathematics.

My collaborators in the 2001 Geometry Group at the Williams REU were Nick Leger of the University of Texas at Austin, and Paul Holt and Eric Schoenfeld of Williams College. Ben Steinhurst from Williams and George Lee from Harvard University will be in the 2002 Geometry Group and they worked with my group during 2001-2002 academic year. Revised versions of our results appear in Chapters 4 and 6.

For three weeks of the summer, the 2001 Geometry Group attended the Clay Mathematics Institute's Summer School on the Global Theory of Minimal Surfaces at the Mathematical Sciences Research Institute in Berkeley, California. Collaborators I met at the summer school were Miguel Carriòn Àlvarez of the University of California at Riverside, Genevieve Walsh of the University of California at Davis, and Shabnam Beheshti of Texas Tech University. A revised version of our joint paper appears in Chapter 7.

Aside from these people who I worked intimately with, there are many others in the world of mathematics at large who made important contributions. In Berkeley, I had a number of helpful conversations with Michael Hutchings, whose theory of double bubble structure underlies the current understanding of the double bubble problem in three and more dimensions, and is treated here in Chapter 3. There I also met David Futer of Stanford University, with whom I had a lengthy correspondence with about the Euclidean version of the Curvature Conjecture appearing in Chapter 4. David's careful work and thoughtful letters contributed greatly to my understanding of the subject

of double bubbles and mathematics in general. During the Summer School, conversations with Matt Kudzin of Indiana State were also very illuminating. I also had several helpful and fun conversations with Manuel Ritoré of the University of Grenada about bubbles in the three-torus and John Sullivan of the University of Illinois at Champaign/Urbana about tilings (and later, by email, about foams).

Andy Cotton and David Freeman, both graduating from Harvard this year, were members of the 2000 Geometry Group, and my group continued their work on double bubbles in spherical and hyperbolic space. I had the pleasure of meeting Andy at MathFest'01 in Madison, and then met again with Andy and David in Cambridge, Massachusetts this past fall, where we talked about double bubbles. At MathFest I also met Wacharin Wichiramala of the University of Illinois Champagne-Urbana, whose results on planar clusters include a lemma that was very important for developing the theory of double bubbles in the two-torus. Wacharin made a number of very helpful suggestions by email during the academic year. At MathFest I also met Joel Foisy, whose Geometry Group in 1992 solved the double bubble problem in the plane, and who proved in his Williams honors thesis a result that is important in Hutchings' structure theory, and whose talk on double bubbles in corners contributed to the Geometry Group's understanding of bubbles on the cylinder and torus.

Notable contributions to the three torus project were made in Berkeley by three of the faculty participants, Michael Dorff, Denise Halverson, and Gary Lawlor, of Brigham Young University, who got us started with *Surface Evolver* computations, and also by David Futer and Matt Kudzin (who I already mentioned), Baris Coskunuzer, Brian Dean, Tom Fleming, Jim Hoffman, Jon Hofmann, Jesse Ratzkin, and Jean Steiner, as well as the entire Geometry Group.

Back at New College, where lots of the writing and tons of the editing took place, Mary Whelan and was a big overall help. In particular, going well beyond her call of duty as an employee of the New College Writing Resource Center, made detailed comments on the Geometry appendix. Conversations with her helped me set the tone for the thesis, and I think enormously contributed to its overall comprehesibility. Yair Kagan produced the illustration of the Hexagonal Honeycomb

appearing at the end of Chapter 7. Holly Barone is the person in charge of interlibrary loans and article copies at the New College library. She worked hard to obtain copies of the books and articles for me. References that were too hard for her to find I gave up on. Tim Teräväinen of New College has had lots of helpful conversations with me about everything; we've lived around each other in three cities and I appreciate his steadfastness. Rob Meyers and Caroline Arruda had the difficult task of being friends with me during my first two years at New College. They helped make things interesting for me here. In particular, Rob and I had lots of fun talking about math together, and it was out of conversations related to his thesis [31] that I began to have some conception of the direction I wanted to go with mine. I am most happy that my dreams about that have come true. Friends who were especially helpful in one way or another during the writing process are Kartina Amin, Justin Clarke-Doane, Selena Lee, Siggy Meek, Ya'el Morowati, Jake Silverstein, Tik Sun, and Stella Tinnirello.

Long-distance from Minneapolis, my sister Zoë Corneli has been a support to me throughout my time at New College.

My dad, Steve Corneli, has had many many wonderful conversations with me over the years. He has also generously sustained all of my living expenses this past semester while I was in the process of writing this thesis, and has covered various other expenses. I confess it here, that I first began to study math at his prompting. I also first began to love it under his tutelage (in geometry and basic calculus) when he asked me point blank whether I really wanted to understand the stuff or not (I did). My dad was also the first person to teach me anything memorable about writing. Judy Knapp is a close friend of my dad's. She has listened to me and encouraged me about many personal issues, and has also moderated my dad's influence on me.

During both the research and writing phases of this project my mother, Lynne Corneli, has made a number of suggestions at key times that improved the quality of my work or writing and that re-focussed my mind. Most of this thesis was composed on a Hewlett-Packard computer she gave

me.

My research at Williams College was supported by the NSF. The Mathematics and Statistics Department at Williams College generously gave me travel support. Expenses incurred in connection with the Summer School were covered by the Clay Mathematics Institute and the Mathematical Sciences Research Institute. I should like to personally thank the organizers of the Summer School: Joel Hass, Arthur Jaffe, Antonio Ros, Harold Rosenberg, Richard Schoen, and Michael Wolf, and especially David Hoffman, who bravely agreed to support the participation of me and three other undergraduates. The Mathematical Association of America provided travel support for my trip to MathFest'01 in Madison, Wisconsin.

A semester of advanced study at the Massachusetts Institute of Technology contributed greatly to this thesis and to my general education in mathematics. This endeavor was underwritten by my paternal grandparents, Kip and Helen Corneli. My professors at MIT were Victor Guillemin, Richard Melrose, and Andras Vašy.

My time at New College was underwritten by my maternal grandparents, Jack and Bea Canchester, and by what used to be called the Dean and Warden's Leadership Scholarship, as well as various other grants from the state of Florida. At New College my professors were Pat McDonald, David Mullins, and Erini Poimenidou (in mathematics), George Rupeiner and Don Colladay (in physics), Catherine Elliot (in economics), Sandra Gilchrist (in biology), and Mac Miller and John McDiarmid (in English).

In addition to all of these people, my thesis is heavily indebted to writings by Almgren [25], Chavel [8], Hutchings [22], Nomizu and Kobayashi [39], Morgan [34], Rudin [45], Spivak [49], and is somewhat better than metaphysically linked to writings by Vinberg [12], Wolf [59], and numerous others.

Mathematics is owned by no one, but writing most certainly is, and I endeavor to point out in the text of the thesis everywhere I borrowed material and to give credit to all of the authors I read

while I wrote. At places where a specific citation is not given, that does not necessarily imply that what I am writing about at that moment is in any way an original idea of my own. In general, I am fairly sure that the distinction between new and old ideas will be clear enough to those who care to think about such things.

DOUBLE BUBBLES IN SPACES OF CONSTANT CURVATURE

Joseph A. Corneli

New College of Florida, 2002

ABSTRACT

The aim of this thesis is to be a comprehensive and self-contained treatment of the known results on area minimizing double bubbles in constant curvature spaces. Difficult proofs of existence and regularity theorems are omitted, as are several more readible proofs that are available (or soon to be made available) in the literature. Included in the thesis are a number of new results, including the reduction of the double bubble conjecture in spherical and hyperbolic space to a problem of asymptotic analysis, a proof of that the least-area way to divide Gauss space ($\mathbf{R}^n$ with Gaussian measure) into three equal pieces consists of three half-hyperplanes meeting at the origin at 120°, and results due to the author and various collaborators on double bubbles it two- and three-dimensional tori. The theoretical background of these developments is surveyed in some detail. A proof of the isoperimetric property of spheres in the classical constant curvature space forms is presented. Various detailed appendices are provided with the hope that persons with little or no background in differential geometry or variational methods will be able to read and enjoy the entire thesis.

- 'Double bubbles'?

- 'Spaces of constant curvature'?

Bubbles are regions in a geometric space (like Euclidean space $\mathbf{R}^n$) that minimize surface area given a volume constraint.

The single bubble or isoperimetric problem seeks the least area way to enclose one volume in a given geometric space.

The double bubble problem seeks the least area way to enclose and separate two given volumes in given geometric space – and so on.

Greek mathematicians knew the solution to the isoperimetric problem in Euclidean space well before the start of the common era. The answer is that the least-area enclosure of a given volume is a sphere, or in two dimensions, a circle. Euler is credited with the first rigorous proof of the isopermetry of circles in the plane. In the mid-eighteen-hundreds, analysts Schwarz (see [47]) and Steiner (see [50]) developed the methods that finally made possible a rigorous proof of the

isoperimetry of spheres in three dimensions. The key idea in their arguments is that symmetrization always reduces perimeter.

The idea of minimizing the surface area for given volume constraint(s) is a classic example of a variational problem. (We have some functional, namely area, defined on the space of all enclosures; we want to know which enclosures with a fixed volume are extrema for this functional.) This type of problem readily generalizes to spaces with non-Euclidean geometry. (The isoperimetry of spheres in the classical non-Euclidean spaces was first shown by Schmidt (see [46]) in the mid-nineteen-hundreds.)

The idea that bubbles or clusters of bubbles solve the least-area enclosure problem comes from our experience in the real world. Empiricism tells us that we should be able to restrict ourselves from the set of all enclosures, on which we impose very few constraints (say only that their boundaries be 'not too bad'), to a subset of enclosures that about which we can say something geometrically substantial. Thus, one of the primary tasks in this problem area was to characterize the geometry of minimizing idealized bubble clusters – an even higher-priority task was to say when a minimizer for the least area problem exists. The basic geometrical properties of the smooth (regular) and non-smooth (singular) sets of minimizing bubble clusters also characterize a class of 'potential minimizers', which are said to satisfy *regularity*. This term is common in variational calculus and partial differential equations, mainly because it turns out that the solutions (minimizers) are usually smooth, that is, regular, almost everywhere. This was proved for the least-area enclosure problem by Almgren [25]; a more specific characterization of the geometry of minimizers was given by Taylor ([53], [54]) and subsequently generalized by Brian White (unpublished).

Once we understand regularity, the problem becomes mostly geometric (and/or computational). Even with regularity, we do not know whether there are a finite number of components in a minimizing bubble cluster, which regular clusters are stable in the sense that they stay regular under volume preserving variationsm, and at the bottom of it all, what shapes are actually minimizing. In non-

standard geometries, the intuition gathered from every-day empiricism wears somewhat thin, and we may have to do some serious thinking to even come up with a reasonable conjecture. Computer simulations can be an aid to intuition.

Spaces with constant curvature are among the simplest things that a geometer can study. This class includes the plane (see Figure 1.1), the sphere (see Figure 1.2), the hyperbolic plane (see Figure1.3), the cylinder, and the flat torus (rectangle or box with identified sides, as in Figures 1.4 and 1.5), as well as the Euclidean, Spherical, and Hyperbolic spaces, and many other examples. Each of these geometrical spaces has the property of being 'pretty much the same' everywhere. This property gives us a relatively large set of tools. In particular, area minimizing bubble clusters in these spaces are described by regularity theorems similar to those proved for Euclidean space. However, a wide range of geometrical and topological complications unknown in Euclidean space make themselves felt in the more general category. These lead to new computational and theoretical challenges.

Figure 1.1: The Euclidean plane, or rather a segment of it, shown here tiled with regular hexagons.

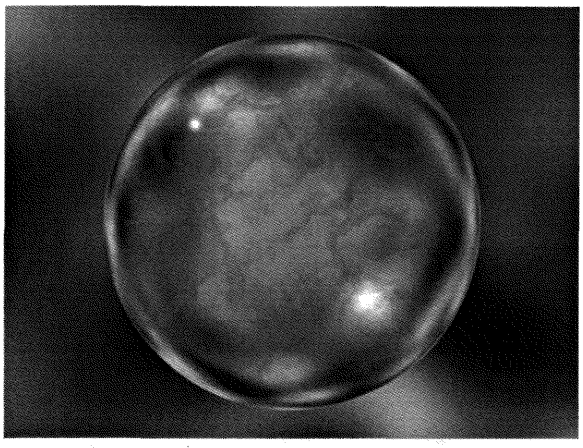

Figure 1.2: The sphere, filled with various media. This computer-generated image looks remarkably like a soap bubble.

**Plan of the Work** Chapter 2 is a review of the results relevant to the subsequent chapters and in other ways important to this thesis. A proof of the minimizing property of spheres for the single bubble problem in the classical constant curvature spaces (spheres, Euclidean space, and hyperbolic space) is presented, and the known results on the regularity properties of minimizing bubble clusters are described. Chapter 3 reviews the known results on the structure of area-minimizing double bubbles. In Chapter 4 we present a partial solution to the double bubble for spherical space $\mathbf{S}^3$ and hyperbolic space $\mathbf{H}^3$. In Chapter 5 we present a solution to a special case of the double bubble problem for $n$-dimensional Gauss space ($\mathbf{R}^n$ with gaussian measure), namely the case in which the two given volumes each take up exactly one third of the volume of the whole space. (This is sort of an 'interlude' since even though this is a perfectly fine space of constant curvature, we won't be directly concerned with curvature properties of the space in this chapter. We do however rely on the known theory for spheres.) In Chapter 6 we present a (more or less complete) solution to the double bubble problem for the flat two torus $\mathbf{T}^2$. In Chapter 7 we present a conjectured solution to the double bubble problem for the flat three torus $\mathbf{T}^3$. And at the end we include a short chapter (really an epilog) that puts together all these various examples and talks in a general way about

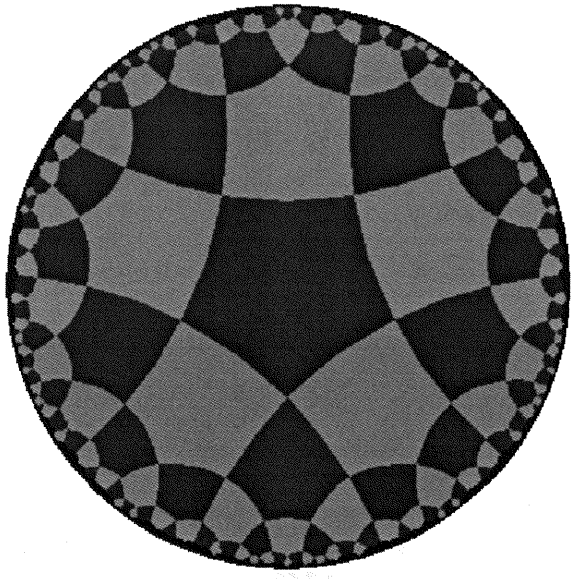

Figure 1.3: The Hyperbolic plane, shown here tiled with regular pentagons. It is not possible to tile the Euclidean plane with regular pentagons, but we can use them to tile the hyperbolic plane because of the way it curves. In particular, the curvature causes areas to expand quickly as you move away from any point – the pentagons look like they are different shapes because of hyperbolic perspective; they are actually exact isometric copies of one another.

what might be true about other related spaces.

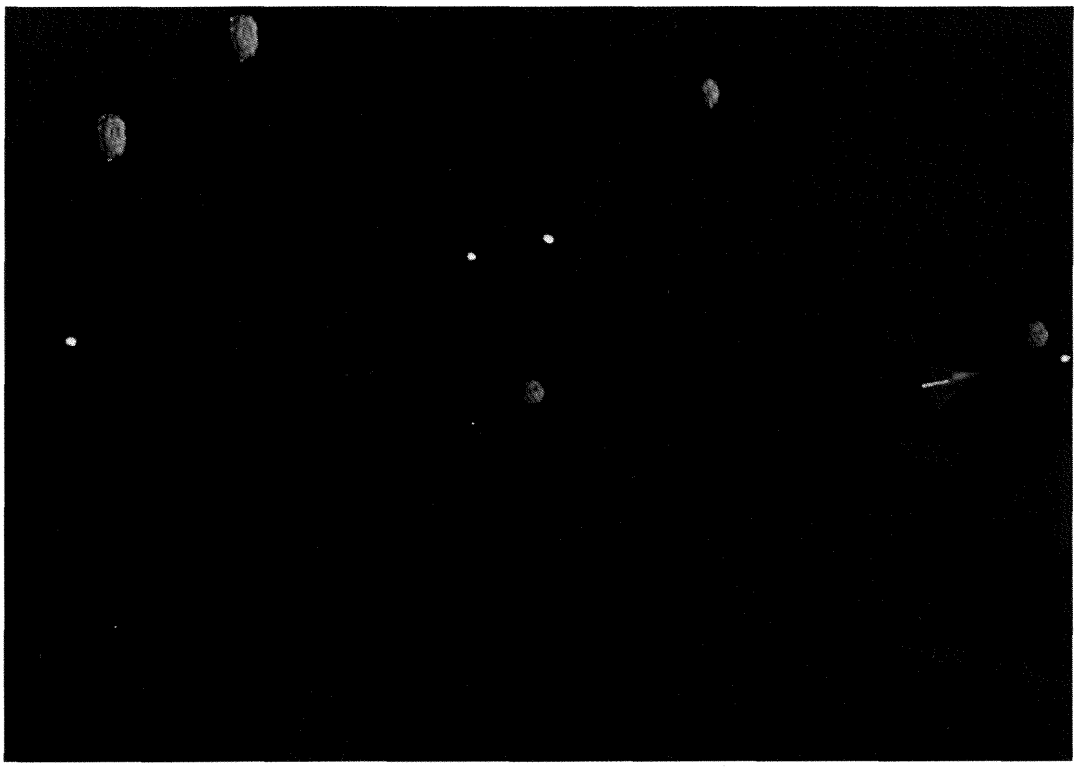

Figure 1.4: The two-torus, viewed from above, with a motif similar to the one in which it it made its debut in popular culture back in 1979. Shots, ships, and asteroids that fly off of the screen on one side instantly reappear on the opposite side (similarly with top and bottom).

## Introduction

**The beginning.** We want to get some feeling for the known results. Other than Euclidean space, the best-understood geometric spaces are the 'classical' non-Euclidean geometries. Understanding the geometry of these spaces and the basic theory of area-minimizing bubbles in them is what is emphasized in this chapter.

**The basics.** We should know what the the simply connected spaces with constant curvature are and some of their basic properties, including their symmetries. These are the classical Euclidean and non-Euclidean geometries; they are collectively called *constant curvature space forms*. The basic properties of constant curvature space forms are reviewed in section 2.1. We should understand the important, well-known, result on the isoperimetric or 'single bubble' problem, which states that of regions with a fixed volume in constant curvature space forms, the ones with the least surface area are round balls. We will present a geometric proof of this fact in section 2.2. We should understand

the basic results of geometric measure theory on the existence and regularity properties of solutions to surface area minimization problems when there are multiple volumes to enclose and separate. These results are reviewed in section 2.3.

In this thesis we are primarily interested in understanding the case of two volumes, or the 'double bubble' problem, and the historical development of this problem up to the current date. It is known that a 'standard double bubble', like that pictured in Figure 2.1, is the least surface area way to enclose and separate two given volumes in $\mathbf{R}^3$ [23], that the equivalent of up one dimension minimizes the analogue of surface area in $\mathbf{R}^4$ [41], and that higher dimensional versions minimize higher dimensional equivalents of surface area when the two volumes to be enclosed are disparate from one another in size. The popularly accepted conjecture is that the standard double bubble is the least surface area way to enclose and separate two arbitrary volumes in Euclidean spaces of arbitrary dimension. We conjecture that standard double bubbles (after being subjected to a subtle redefiniton) give the least surface area way to enclose and separate two given volumes in constant curvature space forms as well. (In Chapter 4 we give a partial proof that this is indeed the case in three dimensions.) We will present the necessary background specific to double bubbles in Chapter 3.

There are some basic features of the double bubble problem that are worth keeping in mind when reading the current chapter however. For constant curvature spaces, one of the key differences between the double bubble problem (and all problems with a higher number of volume constraits) and the single bubble problem is that when there are multi-volume constraints each region in a perimeter minimizing bubble cluster might be disconnected into a number of fragments. In an arbitrary geometric space, a minimizing single bubble might disconnect as well (see Figure 2.2). One way understand why single bubbles in constant curvature spaces do not disconnect is the regularity theorem of Taylor that we discuss in subsection 1.3. This theorem gives explicit conditions on the singular sets present in perimeter minimizing bubble clusters. In particular, in three dimensions, the

boundary surfaces for an area-minimizing bubble cluster always meet at one hundred and twenty degrees along analytic curves. Given a disconnected candidate solution to the single bubble problem, we can use a series of local isometries to move one of the components so that it touches another at a point. *Since this transformation preserves area and perimeter and the final configuration violates regularity, neither the final configuration nor its preimage can be actually be minimizing*. The geometry of the double bubble problem is considerably more complicated than the geometry of the single bubble problem. It is not true, for example, that we can simply translate components of a non-standard double bubble to bring about a violation of regularity (see Figure 2.3 for a simple counter example).

Each of the sections of this chapter and the next requires a good-sized amount of 'modern' geometry and analysis. Many of the ideas (symmetrization, instability, etc.) are straightforward and the reader should be able to get a fairly clear understanding of the theorems without undo difficulty. However, in the hopes that readers will also be able to familarize themselves with the *proofs* of these known results (which I am not squeamish about presenting more or less in full here, to what I hope will be the greater glory of their originators), the standard definitions and results of geometry and analysis needed for the full appreciation of the results of this chapter and its sequel are presented in the appendix.

## 2.1 Constant Curvature Space Forms

**Charter** We should understand what *constant curvature space forms* are and some of their basic properties, including their symmetries. We should understand why there are in some sense only three simply connected spaces with constant curvature.

Three of the most useful geometric spaces in existence are Euclidean space, spherical space, and hyperbolic space (also sometimes called 'Lobachevski' space). These spaces are characterized by,

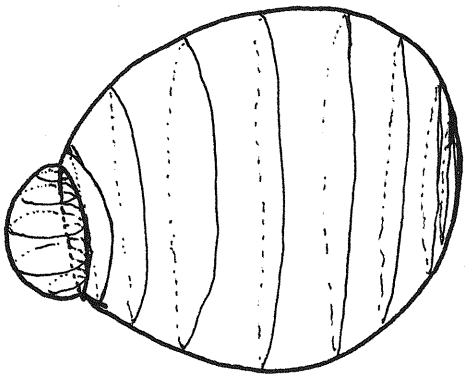

Figure 2.1: Standard Double Bubble

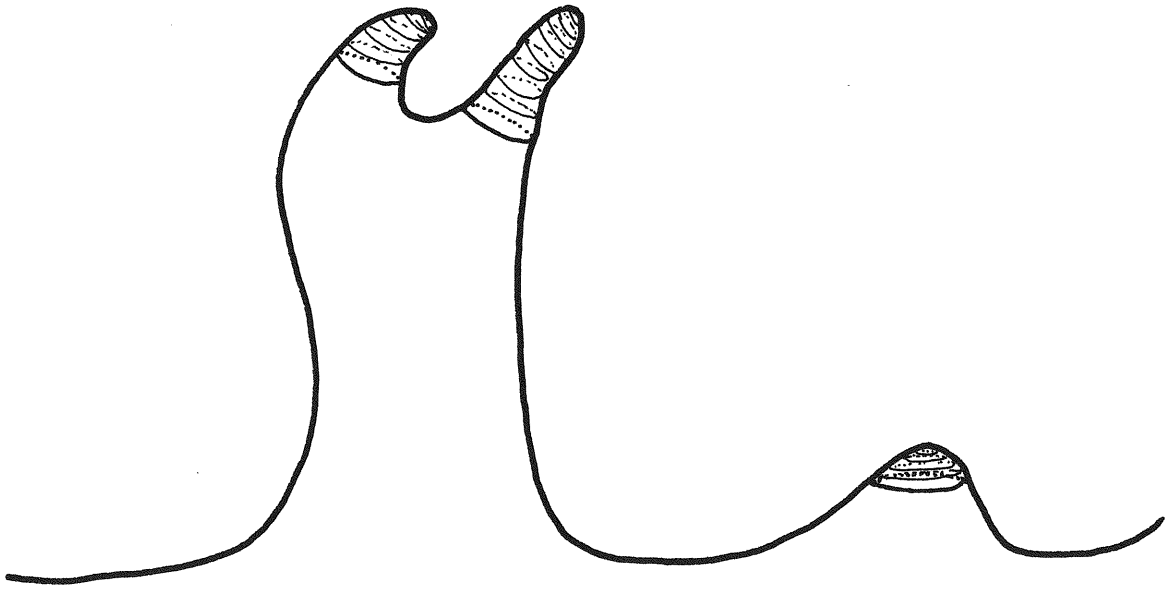

Figure 2.2: Disconnected Single Bubble Minimizer

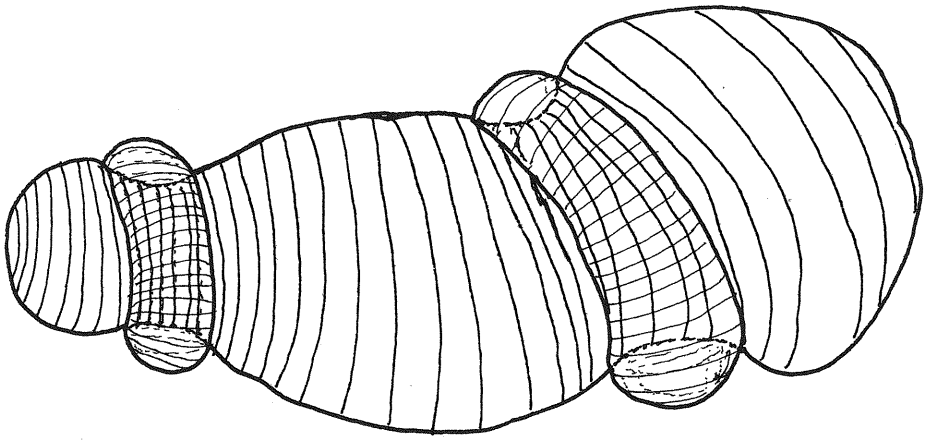

Figure 2.3: Non Standard Double Bubble

among other things, having *constant curvature* of zero, one, and negative one, respectively. By curvature we mean here the sectional curvature, which for the time being we will think of quite loosely as being 'a metric property of two-dimensional subspaces of a given space'. (To speak precisely, sectional curvature is a property of two dimensional subspaces of a tangent space, that is, a local property; we will come to this below. We won't reason in a circle like this in proofs, but in making a first approach to the subject of sectional curvature for constant curvature space forms, it wouldn't be too bad to think first about the curvature properties of subspaces, or, more accurately, submanifolds – such as lines, planes, meridians, and great circles for example – and then make the switch to the correct local formulation when we need it.)

We might mention at this point that there are very classical ways of characterizing these spaces that do not mention curvature. Non-Euclidean geometries were first developed at about the same time that modern geometry had its origins, and were studied using an amalgam of techniques. There are many books on non-Euclidean geometry, of which [3] seems to be very good for both mathematical and historical context.

Here we will work from the basic modern definitions, and we start with Euclidean space $\mathbf{R}^n$.

**Definition 2.1.** We define *n-dimensional Euclidean space* $\mathbf{R}^n$ to be the real vector space made up of

$n$-tuples of real numbers, such as $x = (x_1, x_2, ..., x_n)$, with addition and scalar multiplication defined element-wise, and with distance between points defined by

$$d(x, y) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + ... + (x_n - y_n)^2}.$$

We understand $\mathbf{R}^n$ to carry the metric topology and standard smooth structure (cf. the appendices).

### 2.1.1 A detailed look at Euclidean space $\mathbf{R}^n$

In order to get anywhere in geometry we need to understand Euclidean space very well. The following paragraphs specialize the general treatment of topology and geometry found in the appendix to review the standard facts about Euclidean space.

**1.** We have *curves*, $x(t) = (x_1(t), x_2(t), \ldots, x_n(t))$, where $t$ lies in some interval of real numbers. Curves are frequently taken to be *smooth* in the sense that each of the component functions $x_k$ is smooth, *i.e.* infinitely differentiable.

**2.** From this we get an extended (beyond the calculus 1 version) notion of differentiation, namely that of the *tangent vector to a curve*, written as $x'(t)$, and obtained by differentiating a curve component-wise, so that

$$x'(t) = (x_1'(t), x_2'(t), \ldots, x_n'(t)).$$

**3.** We also have maps between sets in $\mathbf{R}^n$ and $\mathbf{R}^m$, such as

$$x(t_1, \ldots, t_n) = (x_1(t_1, \ldots, t_n), x_2(t_1, \ldots, t_n), \ldots, x_m(t_1, \ldots, t_n))$$

and these maps also have derivatives, this time requiring matrices to represent (so we have for example, the Jacobian, the Hessian, etc.). The maps are said to be of class $C^k$ if the first $k$ of these matrices are non-singular.

**4.** We look at the set of curves through a point $x$ and say that $\mathcal{C}_1 \sim_x \mathcal{C}_2$ if their tangent vectors are the same at $x$. If we identify curves that $\sim_x$ one another, the space of curves through the point $x$ takes on a new identity, namely that of *the tangent space to* $\mathbf{R}^n$ *at* $x$, denoted $T_x\mathbf{R}^n$. So we have tangent spaces, and lots of linear algebra. (This definition of the tangent space varies slightly from the one given in the appendix, but as discussed in Remark C.3, the two definitions are really the same. There we show that the tangent space to $\mathbf{R}^n$ at each point is an isomorphic copy of $\mathbf{R}^n$.) The collection of all the tangent spaces is the *tangent bundle*, which we denote by $T\mathbf{R}^n$.

**5.** We have the Euclidean metric

$$dx_1^2 + dx_2^2 + \ldots + dx_n^2$$

defined on tangent spaces. The meaning of this is as follows: if $\langle \cdot, \cdot \rangle$ denotes the standard inner product of vectors in $\mathbf{R}^n$ (that is, $\langle \cdot, \cdot \rangle : \mathbf{R}^n \times \mathbf{R}^n \to \mathbf{R}, \langle v, w \rangle = \sum_{j=1}^n v_j w_j$) and if $\iota_p : T_p\mathbf{R}^n \to \mathbf{R}^n$ denotes the isomorphism from $T_p\mathbf{R}^n$ to $\mathbf{R}^n$, then *standard Riemannian metric on* $\mathbf{R}^n$ (the Euclidean metric) is defined by

$$T_p\mathbf{R}^n \times T_p\mathbf{R}^n \ni \xi, \eta \mapsto \langle \iota_p(\xi), \iota_p(\eta) \rangle.$$

We often omit the '$\iota_p$'s. At each point, the metric can be written in local coordinates, which fix a basis for the tangent space. In terms of this basis, the metric becomes

$$\xi, \eta \mapsto \xi^T (g_{ij}) \eta,$$

where $g_{ij} = \delta_{ij}$. That is, at each point, the Euclidean metric can be represented by the identity matrix.

**And, the point of all this?** Broadly speaking, we understand curvature to be a smooth function (actually a quadratic form) on the tangent spaces of a manifold. To understand what this means,

we have to understand how to reduce questions about smoothness in a given geometric space (*i.e.* a manifold) to questions about smoothness in $\mathbf{R}^n$, and so we have to be comfortable doing the computations in $\mathbf{R}^n$, where the idea is that everything makes sense and is easy (or, as easy as its going to get).

### 2.1.2 Spherical and hyperbolic spaces

We define spherical and hyperbolic spaces as submanifolds of Euclidean space.

**Definition 2.2.** We define $(n-1)$-*dimensional spherical space* $\mathbf{S}^{n-1}$ to be the set of points a distance one from the origin in $\mathbf{R}^n$, carrying the (metric) topology induced by the metric topology on $\mathbf{R}^n$ and the smooth structure induced by the standard smooth structure on $\mathbf{R}^n$.

**Definition 2.3.** We define $(n-1)$-*dimensional hyperbolic space* $\mathbf{H}^{n-1}$ to be one sheet of a hyperboloid of two sheets

$$x_1^2 + x_2^2 + \ldots + x_{n-1}^2 - x_n^2 = -1 \tag{2.1}$$

(so, this, wherever $x_n > 0$) in the pseudo-Euclidean space $\mathbf{R}^{n-1,1}$ which has the same point-set as Euclidean space but is given the pseudo-Euclidean metric

$$dx_1^2 + dx_2^2 + \ldots + dx_{n-1}^2 - dx_n^2. \tag{2.2}$$

(The pseudo-Euclidean metric here is defined along exactly the same lines as the Euclidean metric above.) We understand $\mathbf{H}^{n-1}$ to carry the same topology and smooth structure as $\mathbf{R}^n$.

*Remark 2.1.* We can change the geometrical properties of spherical and hyperbolic space slightly by purturbing the above definitions; keeping the rest of the definitions the same, we put $\mathbf{S}^{n-1}(\rho)$ equal to the sphere of radius $\rho$, and $\mathbf{H}^{n-1}(\rho)$ equal to one sheet of the hyperboloid defined by the equation

$$x_1^2 + x_2^2 + \ldots + x_{n-1}^2 - x_n^2 = -\rho^2.$$

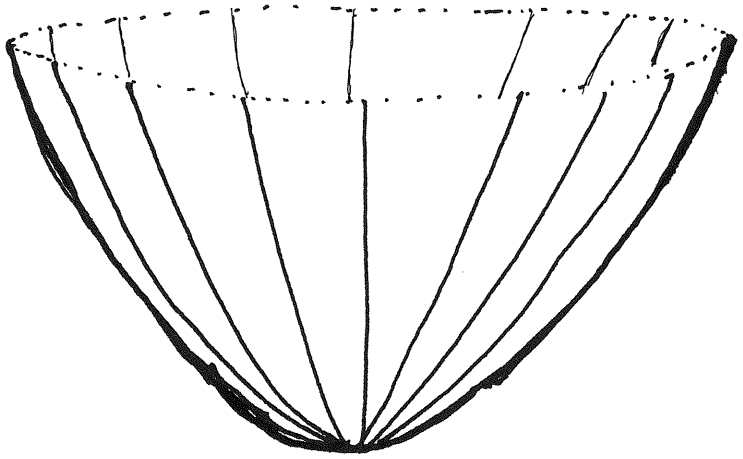

Figure 2.4: One sheet of the hyperboloid of two sheets

**Visualizing higher dimensions and weird spaces.** With all of this tricky abstraction at such an early stage in the game, it seems desirable to take a little time for reflection. The definitions above are, after all, supposed to be intuitive, in one way or another. The key is to figure out a way to actually think about everything geometrically. The basis for geometrical thinking is visualization and that is always lots of fun (one can do this lying on the couch with closed eyes). So for starters, how do we make sense of $\mathbf{R}^4$?

I like to think of this is as space-time – not anything tricky, just nice Cartesian space going on forever in all directions, and nice Galilean time (for lack of a better word) attached to each point in space. So, each point has a clock attached to it, say, and these clocks are syncronized. I like to use the fact that $\mathbf{R}$ is homeomorphic to an open interval to make everything happen in one infinitely long day. Right now its noon, everywhere, but in a few minutes, it will be 12:03. Time's running out! but don't worry, it will take forever to get to 6pm (the scheduled time for our infinite day comes to an end). On the other hand, 1:00 is coming up fairly soon, so we should be getting on with business.

More dimensions are easy: add more hands to the clock – say a hand indicating temperature. Lets say that temperature ranges from an extremely chilly $-90$ degrees to an unendurably hot 120000. Right now, its about 80 degrees in Sarasota, which is nicely described by – not to be self-centered

or anything – $(0, 0, 0, 1200, 80)$. Williamstown Massachusetts is located in $\mathbf{R}^5$ at $(1, 0, 0, 1200, 60)$. On the far side of the moon it is $(0, 15, 0, 1200, -60)$. Perpendicular in space to the plane determined by Williamstown, the moon, and Sarasota we find a point in the upper atmosphere of earth at $(0, 0, 1, 1200, -35)$.

Lets make things a little easier notationally and relabel the time and temperature axes so that 12:00 is 0, and 80 degrees is zero. Then Sarasota is at $(0, 0, 0, 0, 0)$, Williamstown is at $(1, 0, 0, 0, -.12)$, the far side of the moon is at $(0, 15, 0, 0, -3)$ and that special place in the upper atmosphere is $(0, 0, 1, 0, -1.5)$.

Ok, there. Now lets think about things geometrically. The most obvious thing is that Williamstown is pretty close to the north pole $(1, 0, 0, 0, 0)$ of the unit sphere in $\mathbf{R}^5$. The moon is not doing so well in this regard. The upper atmosphere is close to the sphere in most dimensions, but it would have to warm up a fair amount to make it. You might think about this as being sort of like the point $(0, 1, -1.5)$ in three dimensions – which lies due west of the equator of the unit sphere. If the unit sphere in three dimensions was being modeled by the surface of a pool ball, that special place way up in the sky might be stuck to the point on the edge of an 8-ball sitting between your and the corner pocket. The far side of the moon might show up on the tip of your nose at $(15, 0, -3)$, disturbing your concentration as you think about the shot. (If you are wondering how I chose the points in three space, the answer is that I projected onto the second, third, and fifth coordinates. I could have chosen a different model (a very loose sort of 'analogy') by projecting onto three different coordinates. On the other hand what you're probably wondering is how I chose the setting, and in that case you only get a hint – its not really noon in Sarasota.)

Anyway, fun and games aside, we have more exploring to do. We note that there are lots of different lower dimensional spheres. Everywhere the same distance from Sarasota as Sarasota is from Williamstown in the three-dimensional space given by the first three dimensions of $\mathbf{R}^5$ is a *two-sphere*, per usual. Everywhere that is this same distance from that special point in the upper

atmosphere is another two-sphere (and Sarasota is a point on its surface). If I worked on it a little, I could build a standard (2-)double bubble. Now, things get slightly more complicated as we note that the set of points every*when* a distance 1 from now (so, in terms of our original coordinate system, *everywhere* at 11:00 am together with *everywhere* at 1:00 pm) contains within it a set of points on the unit *three-sphere* – only two, actually – the point *here an hour ago* and the point *here an hour into the future*. These points are antipodal, being the poles of the sphere along the time axis. To interpolate between these points (*i.e.* to travel from one to the other and stay inside the sphere) we have to move just right. Let's say we were here an hour ago (not an unsafe assumption) and that we want to be here an hour from now (again, for most of us, this is a fair thing to say). What should we do? Should we sit around and wait? (Some people nod). Not if we want to traverse the three-sphere! Sitting here would take us through the center of the three-sphere, which would be fairly boring*. We have to travel to someplace a unit distance away in space in one hour and then get back in another hour. This means we are going to have to go fast. How can we get to Williamstown in an hour? Not much chance of that happening! Where can we go? Up, I suppose. But, thinking about this from a long-term perspective, that could be risky. The exercise would be better carried out starting in space, where we could designating some point clear of debris as (0,0,0,-1) and then come up on the point fast, and pass it, then gradually slow, turn, go back, and finally pass quickly through the point again at the designated time with no risk of bodily injury. Space also has the benefit of our being able to move in all directions, so we could visit any point on the two-sphere of directions in three-space that makes up the equator of the three-sphere.

So that is the three-sphere. It only a little trickier to build a standard 3-double bubble (which is made out of pieces of three-spheres meeting one another at 120 degrees), but it might take a long time to sort out the details if one wanted to go from scratch – so I'll leave that as a visualization exercise for the reader, should he or she wish to wrack his or her brain. There will be a hint at the

*Funny, am I not? – but in truth, the joke lacks content.

end of this paragraph for those who want the exercise to go more easily.

By a similar construction, everywhere-when-temperature that interpolates at the right rate between points that are one Sarasota-to-Williamstown-length off, one hour off, and one degree off makes up the unit 4-sphere we were talking about a few minutes ago. Materially speaking, this is much easier to traverse, since we can start at one pole in the time dimension, cool things down quickly and then more slowly so that we are one degree colder than we were an hour ago, and then reverse the operation over the course of the following hour. One could also easily combine cooling with driving, and move along a different trajectory from pole to pole. Again, we would be able to see much more of the 4-sphere if we did everything in outer space. However, it is nice to know that there is some higher-dimensional object that we can navigate in our lifetime (with little risk). *Indeed, such things actually show up all over the place when one is looking for them* – so the moral of the story *should* be that higher dimensions can be useful as well as entertaining.

As for hyperbolic space, I should say a few words about that here too. To understand this space in terms of our definition, we should first understand something about $\mathbf{R}^{n-1,1}$. To make things easy on ourselves at first we will restrict to the case that $n = 4$. We will think in a parallel way about the space $\mathbf{R}^{3,1}$ and the space $\mathbf{R}^4$. Indeed, $\mathbf{R}^{3,1}$ is often interpreted as another model for space-time – in this case, we have Cartesian space again, but Einsteinian or relativistic time [29]. Although we think of it as another model for space-time, we also need to keep the two different notions straight, so henceforth we will call $\mathbf{R}^{3,1}$ by its official name *Minkowski space*, The way Minkowski space models space-time is as follows: we have assume the speed of light $c$ is constant (usually we chose this constant to be 1) and we think of vectors in the space as $(x_1, x_2, x_3, ct)$. The pseudo-norm (Minkowski length) $|x|^2 = \sum_{i=1}^{3} x_i^2 - (ct)^2$ induced by the pseudo-Euclidean metric 2.2 gives us an immediate way to define the distance between points $x = (x_1, x_2, x_3, ct_1)$ and $y = (y_1, y_2, y_3, ct_2)$ in $\mathbf{R}^{3,1}$, namely $d(x, y) = |x - y| = \left(\sum_{i=1}^{3}(x_i - y_i)^2\right) - (ct_1 - ct_2)^2$; this is a global definition for distance, *i.e.* it works in much the same way as the Euclidean norm. Here however, distances

are allowed to be negative. The vectors with Minkowski length zero form a cone, since $|\cdot|^2$ is homogeneous. This cone is called the *light cone*, because points that move in straight lines away from the origin with the speed of light stay in the cone. It has two halves, the *forward light cone*, consisting of vectors with $t > 0$ and the *backward light cone*, consisting of vectors with $t < 0$ (similarly, there are forward light cones and backward light cones centered at each point in Minkowski space). All vectors in the light cone are called *light-like*. Vectors with positive Minkowski length are called *space-like* and vectors with negative Minkowski length are called *time-like*, where the names designate the coordinates that are dominant in the vector. The time-like vectors lie in region of $\mathbf{R}^{3,1}$ 'inside' the light cone. The physical interpretation is that particles can not travel faster than light, so tangent vectors must satisfy the inequality $|\frac{\partial x}{\partial t}|^2 = \sum_{i=1}^{3} \left(\frac{\partial x_i}{\partial t}\right)^2 - c \leq 0$. Continuing in the physical vein, we assume that only particles with zero mass have light-like tangent vectors, and particles with positive mass have time-like tangent vectors. The arclength $s = \int_a^b |\frac{\partial x}{\partial t}|^2 d\tau$ in the case of a particle moving with constant velocity becomes $\int_{t_1}^{t_2} \sqrt{c^2 - \sum_{i=1}^{3} \left(\frac{\partial x_i}{\partial t}\right)^2} d\tau = \int_{t_1}^{t_2} c\sqrt{1 - \frac{v^2}{c^2}} d\tau = ct\sqrt{1 - \frac{v^2}{c^2}}\Big|_{t_1}^{t_2}$ and $s/c$ is interpreted as the amount of time the particle takes to travel between two points in space as seen by a fixed observer. If $v \neq 0$, this measurement is the amount of time a clock traveling with the particle takes, scaled by a factor of $\sqrt{1 - \frac{v^2}{c^2}}$. This is a basic property of special relativity; others follow similarly. Three-dimensional hyperbolic space consists of (half of) the vectors in $\mathbf{R}^{3,1}$ with Minkowski length $-1$. This set is asymptotic to the light cone as $t$ increases. One interpretation might be that hyperbolic space consists of all of the positions of a set of particles that explode out of the origin in $\mathbf{R}^3$ at time $t = 1$, and their positions are then plotted with respect to time. The key idea is that the particles speed up as they fly outwards in space at a certain rate, and over time they approach the speed of light. They also spread out as they fly, so that the total mass along each direction goes to zero (assuming the particles were infinitesimal to begin with).

The basic idea is that hyperbolic space spreads out from any given point very quickly, and that it essentially the same as $\mathbf{R}^n$ in all other respects.

Figure 2.5 shows some of the important features of the hyperbolic plane in the Poincaré disk model (which does not look so terribly different from the hyperboloid - but it is different enough to warrent further investigation. Unfortunately we do not have time to show how to map between these representations in this thesis; we direct the interested reader to [16].

The first important feature of this model (which was also used to draw Figure 1.3) is that the boundary of the disk is at infinity, so we are looking at a truly infinite space, although it is captured in finite area. The other important feature of the model is that angles are correct. The circles in the interior of the space *are* circles (*i.e.* boundaries of metric balls in $\mathbf{H}^2$) although their centers are not always in the center of the circles as they are drawn here. The straight lines and pieces of circles that meeting the boundary of the disk at 90 degrees are geodesics. Geodesics that look like pieces of circles have an additional special name – *hypocircles*; we extend this term to all geodesics, and in the future will use these two terms more or less synonymously. If we changed coordinates, so that we were looking down straight onto what is currently the apex of a curved hypocircle, it would look straight – so the only time a distiction can be made is when we work with a given representation of the plane. Circles tangent to the boundary of the disk in the figure are not actually circles in the hyperbolic plane but *horocircles*; they do not have well-defined radii. These can not be unstuck from infinity by a coordinate change. A related fact that sheds some light on the situation is that two geodesics that appear to meet at infinity never actually intersect, but become arbitrarily close to one another.

The picture is similar in three dimensions: things that look like pieces circles in this picture will become a pieces of spheres, the straight lines will become a flat disks, and the Poincaré model itself will become a solid ball. The new vocabulary that goes along with the construction just replaces 'sphere' everwhere 'circle' was found previously. Geodesics are again straight lines and pieces of circles that meet the boundary of the ball at 90 degrees. If we add more dimensions, the definitions and terminology develops along the same lines as it did here.

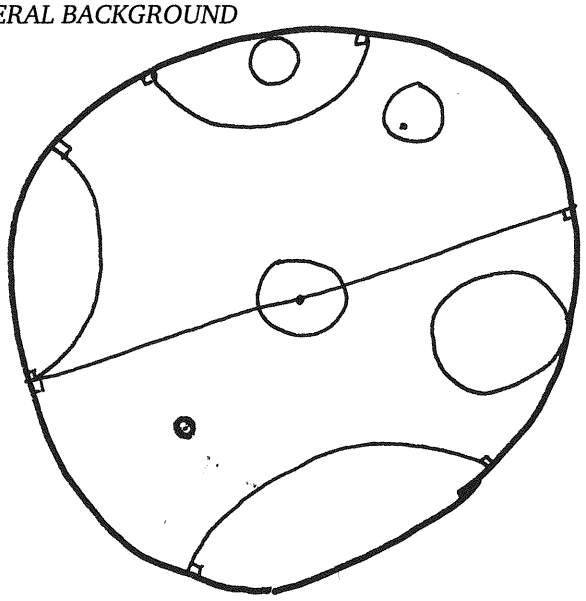

Figure 2.5: Horocircles, hypocircles, circles.

One definition that really needs to be understood clearly in a number of places later on in the thesis is that of a *hyperplane*. In $\mathbf{R}^n$, this is just an embedded isometric copy of $\mathbf{R}^{n-1}$. In Euclidean space, hyperplanes cut the space in two pieces: the line divides the plane, the plane divides space, space divides space-time (for example, everywhere-now is a hyperplane) and so on. Embedded isometric copies of Euclidean spaces with dimension less than $n$ do not separate $\mathbf{R}^n$ – a line does not separate space, a plane does not separate space-time. This is seen to be true because a line will *never* seperate space and a *line-always* is a two-plane in space-time, whereas *space-always* is space-time. In other words, after rotating, at any given point in time a two-plane in space-time is just a line in space, so it doesn't ever space. Furthermore, by definition, a line-always goes on for all time, so it doesn't separate time either, and hence does not separate space-time. And similarly for higher dimensions. In spheres and in hyperbolic space, similar ideas apply - so, in the $n$-sphere, an equatorial $(n-1)$-sphere is a *hypersphere*; in hyperbolic space, a (hyperbolic) $(n-1)$-plane is a *hyper-hyperbolic plane*.). With tori, and other more tricky geometries, it is a little different, since here hyperplanes do not always cut the space in two. Hyperplanes are just one example of a broader category, namely *hypersurfaces*, which are embedded submanifolds of one dimension lower than the ambient manifold.

We will say one last thing about spheres. This is that $\mathbf{S}^n$ is in general not only a hypersurface in $\mathbf{R}^{n+1}$, but a *hypersurface of revolution*. That $\mathbf{S}^2$ is a surface of revolution probably does not come as a major revelation. The fact that $\mathbf{S}^3$ is a hypersurface of revolution may take a little explaining. First, lets walk through an illustrative example of rotation *in* $\mathbf{S}^3$. From this example we will get the ideas we need to define hypersurfaces of revolution.

There are two steps to the illustration. The first step should be familiar. Start with a half circle $C$ with radius $r$ in the upper half plane $\mathbf{R}^2_+$, sitting on the $x$-axis. We revolve $C$ around the $x$-axis and we call the set of points it hits '$\mathbf{S}^2$'. Now the second step: we will take the upper half of $\mathbf{S}^2$ (let's call it $C'$) and perform similar operations to generate $\mathbf{S}^3$. We will regard $C'$ as sitting on $\mathbf{R}^2$ inside of $\mathbf{R}^3_+$ which is itself sitting inside of $\mathbf{R}^4$. But we also keep in mind the idea of $C'$ as sitting inside $\mathbf{S}^3$ (specificall, we will think of $C'$ as half of an equatorial two-sphere). We now rotate $C'$ by interpolating from each of its points in the manner described previously. What we see in $\mathbf{R}^4$ are images of $C'$, getting smaller and earlier, all centered on the same point $p$ in $\mathbf{R}^2$ (*i.e.* the same point in space). Eventually these images shrink all the way down to $p$ (the time then is exactly $-r$), reemerge *reflected across* $\mathbf{R}^2$, and begin to grow and get later again. When the the image in $\mathbf{R}^3$ is equal to the reflection of $C'$ across $\mathbf{R}^2$, the time is zero again. Now the images shrink down to $p$ again, getting later all the while, and when they hit $p$ this time, the clock reads $r$. To make the final turn, the images grow again, and when they get back to $C'$, the clock is back to zero; this completes the illustration.

At this point it would be natural to ask what we have actually done. This is a question perhaps as much due to the fact that spheres are so fearfully symmetric as it is to the fact that we are working in four dimensions. But we also note is that there are some big differences between the lower-dimensional case (the first step of the example) and the higher-dimensional case (the second step). The main difference that concerns us here is that none of the points on $C'$ were fixed in the second step (whereas the two endpoints of $C$ were fixed in the first step). Something that *is* fixed (in space-

time) is the location of the point $p$, since its distance from itself is zero (and distance-from-$p$ was the parameter we used to determine how far out in the time direction we had to go). If we now examine a surface with less symmetry – the top half of a cylinder for example – we can define a rotation about the (spatial) axis of symmetry of the full cylinder by treating each half-circle segment of the half-cylinder in the same way we treated the meridinal segments of $C'$. Taking what we learn from this example, we can define the *rotation into the fourth dimension* for a rotationally symmetric surface $S$ by treating each of the circles that make up $S$ as if it was a meridian in the two-sphere sitting inside $\mathbf{S}^3$. In particular, we can take $\mathbf{S}^2$ and viewing it as a subset of $\mathbf{R}^3$, think of it as being a surface of revolution about some fixed axis $\ell$. If we now rotate into the fourth dimension as described, we trace out a copy of the three sphere. As in the first step of the illustration, two points are fixed for the entire rotation, namely the points where $\ell$ intersects $\mathbf{S}^2$. Since the time at these points is always zero, it might be fitting to call them East and West poles of the three sphere, since they lie on line that is perpendicular to the time axis (which we usually say runs north and south).

Now, the hint for how to construct a standard 3-double bubble should make it very easy: start with a standard 2-double bubble and revolve it around its spatial axis of symmetry.

### 2.1.3 Three constant curvature space forms.

Given the intuitive definitions for Euclidean, spherical, and hyperbolic space we saw above, it may seem reasonable that they should have constant sectional curvature. (We're still thinking of this in very loose terms; the point being that we know intuitively which two dimensional subspaces of $\mathbf{R}^n$, $\mathbf{S}^n$, and $\mathbf{H}^n$ we will be looking at. They are the hyperplanes, equatorial spheres, or hyper-hyperplanes.)

A quick proof that the curvatures are constant and 'signed', so that Euclidean space has zero curvature, $\mathbf{S}^n$ has constant positive curvature, and $\mathbf{H}^n$ has constant negative curvature, will be given in this subsection. A simple corollary shows that by scaling the ambient $\mathbf{R}^n$ we can normalize the

curvature of $\mathbf{S}^{n-1}$ to be 1 and by scaling the ambient $\mathbf{R}^{n-1,1}$ we can normalize the curvature of $\mathbf{H}^{n-1}$ to be $-1$.

This suggests that there are in some sense only three constant curvature space forms. The exact sense in which this is true is that *up to scaling these are the only simply connected spaces with constant curvature, i.e.* that $\mathbf{R}^n$, $\mathbf{S}^n$, and $\mathbf{H}^n$ are the only constant curvature spaces in which all loops are contractible to a point, *i.e.* they are the only constant curvature space forms. (The fact that these spaces are all simply connected is easy to see, if one is good at visualizing things in many dimensions.) The *proof* that these are the only simply connected spaces with constant curvature is not particularly easy, and we omit it (see [12] or [59] for the details).

We henceforth give the constant curvature space forms a *new* collective name, $\mathcal{R}^n$, where the $\mathcal{R}$ refers to the (Riemann) curvature (tensor), which is all that we need to specify in order to fix a particular constant curvature space form.

**The Manifold Curvatures.** There is not much left to do but to plunge in and recall the official definitions. The various curvatures of Riemannian geometry are as incestuous and as plentiful could possibly be desired, so there could be a lot for us to recall if we liked; we will however try to be moderate. *It may be helpful to refer to the appendix on Geometry Preliminaries when reading this section.*

**Definition 2.4.** We define the *Riemann curvature operator* $R$ of a Riemannian manifold $M = (X, \langle\cdot,\cdot\rangle)$ with Levi-Civita connection $\nabla^{\mathrm{LC}}$ and commutator $[\cdot,\cdot]$ to be the map from $\mathrm{vect}(M) \times \mathrm{vect}(M) \times \mathrm{vect}(M)$ to $\mathrm{vect}(M)$ determined by the following action on vector fields:

$$R(\mathcal{U},\mathcal{V})\mathcal{W} = \nabla^{\mathrm{LC}}(\mathcal{V}, \nabla^{\mathrm{LC}}(\mathcal{U},\mathcal{W})) - \nabla^{\mathrm{LC}}(\mathcal{U}, \nabla^{\mathrm{LC}}(\mathcal{V},\mathcal{W})) - \nabla^{\mathrm{LC}}([\mathcal{V},\mathcal{U}],\mathcal{W}).$$

*Remark 2.2.* Note that $R$ is local in the sense that $(R(\mathcal{U},\mathcal{V})\mathcal{W})|_p$ depends only on $\mathcal{U}|_p, \mathcal{V}|_p$ and $\mathcal{W}|_p$.

To be precise, in terms of local coordinates $\{u_i\}_{i=1}^n$, we have

$$R\left(\frac{d}{du_j},\frac{d}{du_k}\right)\frac{d}{du_i}=\sum_{l=1}^{n}R^l_{ijk}\frac{d}{du_l} \tag{2.3}$$

where the '$R^l_{ijk}$'s are functions from the manifold to the reals defined by

$$R^l_{ijk}=\frac{d}{du_k}\Gamma^l_{ik}-\frac{d}{du_j}\Gamma^l_{ik}+\sum_{r=1}^{n}\Gamma^r_{ij}\Gamma^l_{rk}-\Gamma^r_{ik}\Gamma^l_{rj}. \tag{2.4}$$

The proof is just by expanding $R\left(\frac{d}{du_j},\frac{d}{du_k}\right)\frac{d}{du_i}$ in terms of its definition and the definition of a connection (DefinitionC.11). From the definition of the Riemann curvature operator, this is

$$\nabla^{\mathrm{LC}}\left(\frac{d}{du_k},\nabla^{\mathrm{LC}}\left(\frac{d}{du_j},\frac{d}{du_i}\right)\right)-\nabla^{\mathrm{LC}}\left(\frac{d}{du_j},\nabla^{\mathrm{LC}}\left(\frac{d}{du_k},\frac{d}{du_i}\right)\right)-\nabla^{\mathrm{LC}}\left(\left[\frac{d}{du_k},\frac{d}{du_j}\right],\frac{d}{du_i}\right)$$

(but $\left[\frac{d}{du_k},\frac{d}{du_j}\right]$ is zero; we apply the definiton of the connection coefficients (Equation C.5) to the first two terms)

$$=\nabla^{\mathrm{LC}}\left(\frac{d}{du_k},\sum_{m=1}^{n}\Gamma^m_{ij}\frac{d}{du_m}\right)-\nabla^{\mathrm{LC}}\left(\frac{d}{du_j},\sum_{m=1}^{n}\Gamma^m_{ij}\frac{d}{du_m}\right)$$

(by additivity in the second component for derivations (Equation C.2) this is)

$$=\sum_{m=1}^{n}\left(\nabla^{\mathrm{LC}}\left(\frac{d}{du_k},\Gamma^m_{ij}\frac{d}{du_m}\right)\right)-\sum_{m=1}^{n}\left(\nabla^{\mathrm{LC}}\left(\frac{d}{du_j},\Gamma^m_{ij}\frac{d}{du_m}\right)\right)$$

(combining the summations)

$$=\sum_{m=1}^{n}\left(\nabla^{\mathrm{LC}}\left(\frac{d}{du_k},\Gamma^m_{ij}\frac{d}{du_m}\right)-\nabla^{\mathrm{LC}}\left(\frac{d}{du_j},\Gamma^m_{ij}\frac{d}{du_m}\right)\right)$$

(and by the Leibnitz rule for connections (Equation C.3) and the definition of the connection coefficients again this is)

$$=\sum_{m=1}^{n}\left(\left(\left(\frac{d}{du_k}\Gamma^m_{ij}\right)\frac{d}{du_m}+\Gamma^m_{ij}\sum_{r=1}^{n}\Gamma^r_{mk}\frac{d}{du_r}\right)-\left(\frac{d}{du_k}\Gamma^m_{ik}\right)\frac{d}{du_m}+\Gamma^m_{ik}\sum_{r=1}^{n}\Gamma^r_{mj}\frac{d}{du_r}\right)$$

(which, upon collecting like terms, shows that the scalar coefficients are the '$R^l_{ijk}$'s defined by Equation 2.4.)

**Definition 2.5.** With $M$ as above, we define the *Riemann curvature tensor* to be the map

$$(\mathrm{vect}(M))^4\times M\ni(\mathcal{U},\mathcal{V},\mathcal{W},\mathcal{X},p)\mapsto\langle R(\mathcal{U},\mathcal{V})\mathcal{W},\mathcal{X}\rangle_p\in\mathbf{R}. \tag{2.5}$$

*Remark 2.3.* If we have local coordinates, the Riemann curvature tensor is locally computable in terms of the connection coefficients (and so, in terms of the metric). Using the local definition the Riemann curvature operator (Equations 2.3 and 2.4), we have

$$\left\langle R\left(\frac{d}{du_j}, \frac{d}{du_k}\right)\frac{d}{du_i}, \frac{d}{du_m}\right\rangle = R^l_{ijk} = \frac{d}{du_k}\Gamma^l_{ik} - \frac{d}{du_j}\Gamma^l_{ik} + \sum_{r=1}^{n}\Gamma^r_{ij}\Gamma^l_{rk} - \Gamma^r_{ik}\Gamma^l_{rj}. \tag{2.6}$$

In particular, a computation in the appendix (Corollary C.1) shows that the connection coefficients all vanish in the case of $\mathbf{R}^n$, which implies that the Riemann curvature tensor associated with $\mathbf{R}^n$ is identically zero.

**Definition 2.6.** With $M$ as above, let $p \in M$ and let $\xi, \eta$ be vectors in $T_pM$. Define

$$\kappa(\xi, \eta) = \langle R(\xi, \eta)\xi, \eta\rangle,$$

and define

$$\kappa_1(\xi, \eta) = \langle \xi, \xi\rangle\langle \eta, \eta\rangle - \langle \xi, \eta\rangle^2$$

Finally, let

$$K(\xi, \eta) = \frac{\kappa(\xi, \eta)}{\kappa_1(\xi, \eta)}.$$

$K$ is the *sectional curvature at p of the plane determined by $\xi$ and $\eta$.*

*Remark 2.4.* The idea is that in $\mathcal{R}^n$, $K$ depends trivially on $\xi$ and $\eta$, and $p$. For example, in Remark 2.6 we saw that the Riemann curvature tensor on $\mathbf{R}^n$ is identically zero; this implies that the sectional curvature of $\mathbf{R}^n$ is identically zero.

**$\mathbf{R}^n$, $\mathbf{S}^n$, and $\mathbf{H}^n$ have the right curvatures.** We have already done the case of Euclidean space; as summarized in Remark 2.4, the sectional curvature of $\mathbf{R}^n$ is identically zero. We say that Euclidean space is *flat*.

Now, spheres. Using stereographic projection from the north pole,

$$\mathbf{S}^n(\rho) \setminus \text{south pole} \ni y = (y_1, \ldots, y_{n+1}) \mapsto u = (u_1, \ldots, u_n) \in \mathbf{R}^n \subset \mathbf{R}^{n+1}.$$

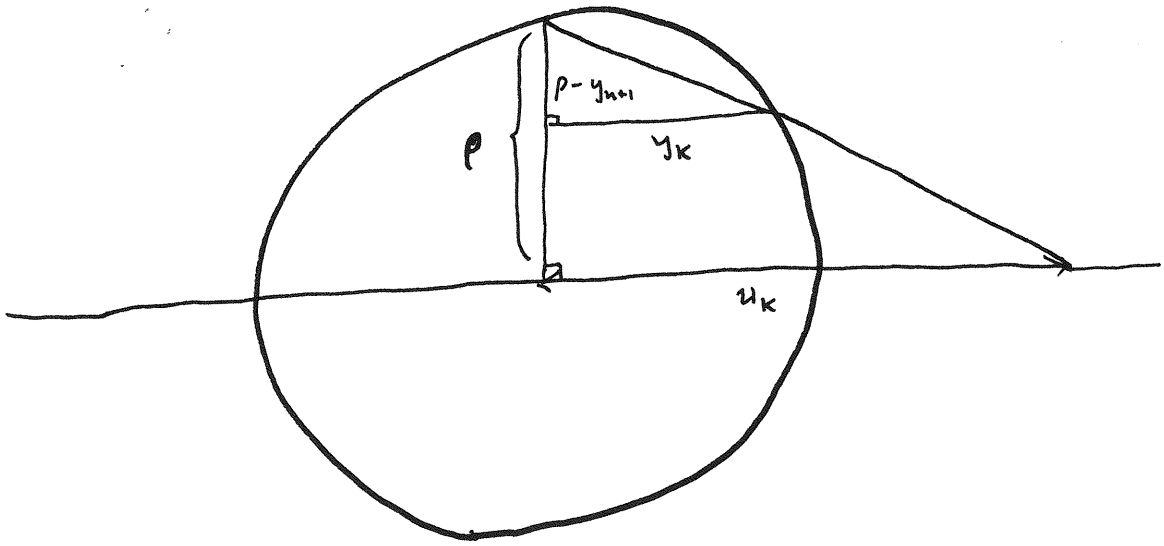

Figure 2.6: Stereographic projection

By similar triangles in Figure 2.6, we have

$$\frac{y_k}{\rho - y_{n+1}} = \frac{u_k}{\rho},$$

*i.e.*

$$y_k = \frac{u_k(\rho - y_{n+1})}{\rho},$$

hence

$$y_{n+1} = \frac{|u|^2 - \rho^2}{|u|^2 + \rho^2}\rho,$$

and

$$(y_1, \ldots, y_n) = \frac{2\rho^2}{\rho^2 + |u|^2}u.$$

We put $\bar{y} = (y_1, \ldots, y_n)$ and compute:

$$\begin{aligned} d\bar{y} &= 2\rho^2 \frac{(\rho^2 + |u|^2)du - 2u(u \cdot du)}{(\rho^2 + |u|^2)^2} \\ dy_{n+1} &= 4\rho^3 \frac{u \cdot du}{(\rho^2 + |u|^2)^2} \end{aligned}$$

and so

$$\begin{aligned} |d\bar{y}|^2 &= 4\rho^4 \frac{(\rho^2 + |u|^2)^2|du|^2 - 4\rho^2(u \cdot du)^2}{(\rho^2 + |u|^2)^4} \\ dy_{n+1}^2 &= 16\rho^6 \frac{(u \cdot du)^2}{(\rho^2 + |u|^2)^4}. \end{aligned}$$

Summing, we have

$$ds = \sum_{k=1}^{n+1} dy_k^2 = 4\rho^4 \frac{|du|^2}{(\rho^2 + |u^2|)^2},$$

*i.e.*

$$g_{jk} = \left\langle \frac{d}{du_j}, \frac{d}{du_k} \right\rangle = \frac{4\delta_{jk}}{(1 + |u|^2/\rho^2)^2}.$$

Using the formula for connection coefficients found in the appendix (Equation C.15), this implies that

$$\Gamma^i_{jk}(u) = \frac{-2}{\rho^2 + |u|^2}(\delta_{ik}u_j + \delta_{ji}u_k - \delta_{jk}u_i).$$

We now invite the reader to use the local formula for the Riemann curvature tensor (Equation 2.6) to show (by a long and nasty computation) that the sectional curvature of $\mathbf{S}^n(\rho)$ is $\rho$.

Finally, hyperbolic space. There are a couple of nice models for hyperbolic space: the disk model, and the upper half space model. It is sometimes helpful to be able to switch between the models.

If we start with a disk with the metric

$$ds = \frac{4|dz|^2}{(1 - |z|^2/\rho^2)^2},$$

then the sectional curvature will turn out to be $-1/\rho$. We show that in the case $\rho = 1$, the sectional curvature is $-1$. It is preferential to work in $\mathbf{R}^n_+$ with the metric

$$ds = \frac{|du|^2}{(u_n)^2},$$

*i.e.*,

$$g_{ij} = \frac{\delta_{ij}}{(u_n)^2}$$

which implies that

$$\Gamma^i_{ij} = -(u_n)^{-1}(\delta_{jn}\delta_{ik} + \delta_{kn}\delta_{ji} - \delta_{in}\delta_{jk}),$$

and so for $j, k \in \{1, \ldots, n-1\}$ we have

$$\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_j}, \frac{d}{du_k}\right) = -(u_n)^{-1}\delta_{jk}\frac{d}{du_n}$$

$$\begin{aligned}
\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_n},\frac{d}{du_k}\right) &= -(u_n)^{-1}\frac{d}{du_k}\\
\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_n},\frac{d}{du_n}\right) &= -(u_n)^{-1}\frac{d}{du_n}\\
\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_k},\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_j},\frac{d}{du_n}\right)\right) &= -(u_n)^{-1}\delta_{jk}\frac{d}{du_k}\\
\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_j},\nabla^{\mathrm{LC}}_{\mathbf{H}^n}\left(\frac{d}{du_k},\frac{d}{du_k}\right)\right) &= -(u_n)^{-1}\frac{d}{du_j}.
\end{aligned}$$

Therefore, when $j \neq k$ we have

$$R\left(\frac{d}{du_k},\frac{d}{du_j}\right)\frac{d}{du_k} = -(u_n)^{-2}\frac{d}{du_j}$$

which implies by the definition of sectional curvature that $K(\frac{d}{du_j},\frac{d}{du_j}) = -1$ and similarly

$$R\left(\frac{d}{du_n},\frac{d}{du_j}\right)\frac{d}{du_n} = -(u_n)^{-2}\frac{d}{du_j}$$

so that $K(\frac{d}{du_j},\frac{d}{du_n}) = -1$.

**Geodesics and Metric Balls.** This paragraph mainly reviews and specializes material found in the appendix. We also define spherical coordinates for constant curvature space forms.

The shortest paths between points are called geodesics. One can go through the derivations in some detail, but to summarize: in Euclidean space $\mathbf{R}^n$, geodesics are straight lines; in spherical space $\mathbf{S}^n$, geodesics are '$\mathbf{S}^1$'s with the same curvature as $\mathbf{S}^n$; and in hyperbolic space, geodesics are '$\mathbf{H}^1$'s with the same curvature as $\mathbf{H}^n$.

More generally, we have the following:

**Definition 2.7.** A submanifold $T \subset M$ is *totally geodesic* if every geodesic in $M$ that has an open segment in $T$ never leaves $T$.

Because the geodesics in $\mathcal{R}^n$ are easy, it is easy to see what the totally geodesic submanifolds are; they are the $k$-dimensional planes or spheres with the same curvature as $\mathcal{R}^n$.

For the sake of understanding the next several section(s) we need to know what metric balls (also interchangably called *disks*) in $\mathcal{R}^n$ look like. They are for the most part like balls or disks in Euclidean space. Disks on spheres are sometimes also called *spherical caps*, and they do not always look a lot like a disk in Euclidean space. Every round circle in $\mathbf{S}^2$ cuts off two spherical caps, so hemispheres as well as things both bigger and smaller are examples.

Round balls are associated with a very convenient coordinate system, namely, spherical coordinates. These are very easy to write down in $\mathcal{R}^n$ [7, page 39]. If $K > 0$, we take $(t, \xi) \in [0, \pi/\sqrt{K}) \times \mathbf{S}^{n-1}$, and if $K \leq 0$ we take $(t, \xi) \in [0, \infty) \times \mathbf{S}^{n-1}$; then there is some coordinate system with respect to which the metric can be written as

$$ds^2 = (dt)^2 + S_K^2(t)|d\xi|^2,$$

where $S_K^2(t)$ is the solution to the differential equation

$$y'' + Ky = 0,$$

with the initial conditions

$$S_K(0) = 0,\ S_K'(0) = 1.$$

If $K > 0$, the solution is $S_K(t) = (1/\sqrt{K}) \sin \sqrt{K}t$ , if $K < 0$, the solution is $S_K(t) = (1/\sqrt{-K}) \sinh \sqrt{-K}t$ and if $K = 0$, the solution is $t$.

This is a nice way to summarize facts that can be determined by direct calculation, using the coordinates $x = p + t\xi$ in $\mathbf{R}^n$, $x = (\cos t/\rho)p + (\sin t/\rho)\xi$ in $\mathbf{S}^n(\rho)$, or (here we center on 0) $x = \rho \tanh(t/2\rho)\xi$ in $\mathbf{H}^n(\rho)$ and then finding the differentials.

## 2.2 Isoperimetric problem in constant curvature space forms

**Charter** We should understand the know results on the 'single bubble' or isoperimetric problem, which states that of regions with a fixed volume in constant curvature space forms, the ones with the least surface area are round balls.

In order to eliminate any potential confusion at such an early stage, and because it is at least somewhat relevant in the arguments which follow, the first note we'll make is that 'isoperimetric' (same-perimeter) is a fine, if somewhat obscure, name for the problem of finding the *least* perimeter needed to enclose a *fixed* area. The key idea to the simple argument that proves this is that maximal area increases monotonically with perimeter. This is obvious for Euclidean and hyperbolic space; for spheres this is only true for volumes that take up up to half of the volume of the space, but after that, we switch to think of the other smaller volume as the one being enclosed, so the same argument applies.

Here is the argument. Each perimeter $P$ has a set of maximal-area objects $S(P)$ associated to it. Obviously all the elements of $S(P)$ must have the same area, which we'll call $A$. Change perspectives, and each area $A$ has a set of perimeter-minimizing obects associated to it. We claim that this set is exactly $S(P)$. The proof is that if $p < P$ and there is some enclosure $E$ with perimeter $p$ and area $A$, so perimeter does not increase monotonically; this is a contradiction.

There are in fact a number of other equivalent formulations of the isoperimetric problem, but the one we want to keep in the forefront of our minds is the cannonical 'least perimeter for a given area' version. More generally, we will talk about the domains with the least surface area for a given volume, where we think in terms of the following formal definitions.

**Definition 2.8.** A *domain* in a manifold $M$ is an open set whose boundary fits the needs at hand;

usually our proofs only require that the boundaries be embedded $C^1$ or $C^2$ submanifolds.

In defining domains, we need to pick something that works as a model for bubbles. In the later sections, when we work with more than one enclosed region, we will be allowing a lot of singular behavior on the boundaries, but at this stage we want regularity up front. This means, for example, that unlike Zenodorus and Pappus, we won't be thinking about how competative the Euclidean solids are with the sphere. In the much more general category we will be working with later, it is possible to show that the boundaries of competative single bubbles really are smooth, so our restrictive-seeming differentiability assumption will be vindicated.

**Definition 2.9.** The *volume* of a domain $\Omega$ in $\mathbf{R}^n$ is the Lebesgue measure of $\Omega$. We write $\mu_n(\Omega)$ for the volume of a domain $\Omega$. In $\mathcal{R}^n$ volume is defined using the analogue of Lebesgue measure (see the appendix on Analysis).

*Remark 2.5.* This is one of the reasons we require differentiability; we want to make the set of domains to be in the $\sigma$-algebra of Lebesgue measurable subsets of $\mathbf{R}^n$. (Or, for $(R)^n$, in the analogous $\sigma$-algebra.)

**Definition 2.10.** We define the *surface area* of $\Omega$ to be the derivative at zero with respect to $\epsilon$ of the volume of an $\epsilon$-tube around $\Omega$ (an *$\epsilon$-tube* $\Omega_\epsilon$ is the set of points $p \in \mathcal{R}^n$ such that $d(p, \Omega) \leq \epsilon$). We write this in symbols as

$$\mu_{n-1}(\partial\Omega) = \left.\frac{d}{d\epsilon}\right|_{\epsilon=0} \mu_n(\Omega_\epsilon).$$

Note that $\mu_{n-1}$ as surface area is the same as $\mu_{n-1}$ as $(n-1)$-dimensional measure; Definition 2.10 gives a way to restrict $n$-dimensional measure to $(n-1)$-dimensional sets. However, as with the definition of volume, the definition of surface area relies on the assumption that our domains are bounded by differentiable curves. (We could have defined surface area with a slightly relaxed hypothesis; for example, *piecewise* differentiable would be ok.) Definition 2.10 is only the beginning of a sequence of very interesting things that can be done with tubes. See Gray [17] for some of the

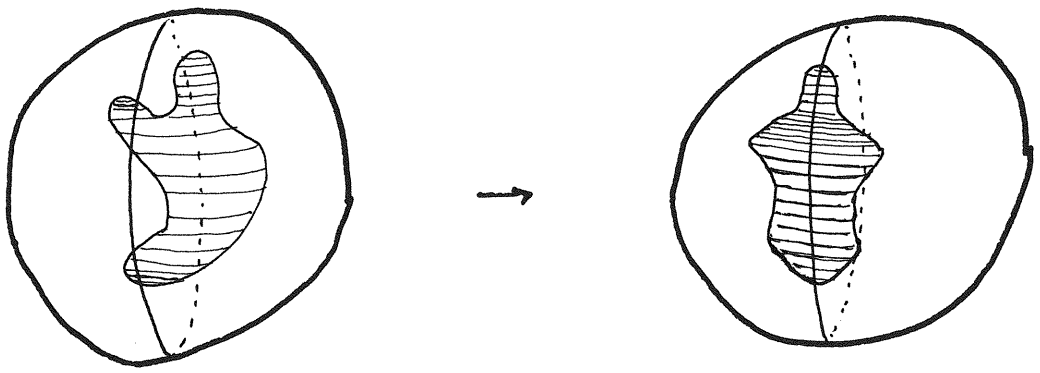

Figure 2.7: The Steiner symmetrization of a domain on the sphere.

most important details.

**Theorem 2.1 (Isoperimetric property of metric balls).** In constant curvature space forms, the domains with least surface area that enclose a given volume are the metric balls.

### 2.2.1 Proof of the isoperimetric property of round balls

We present a proof with a fairly geometric flavor based on an argument due to Figiel, Lindenstrauss, and Milman [52] which covers the spherical case. This proof was first encountered by the author in the text of Chavel [8] where it is modified to treat the Euclidean and hyperbolic cases. This restatement of Theorem 2.1 is based on that found in Chavel (*op. cit.*, page 283, Theorem 6.7) although I prefer in the notation of Figiel *et al.* and I reproduce their argument for the spherical case.

**Restatement of Theorem 2.1.** Let $A$ be the closure of a domain in $\mathcal{R}^n$. For a given $A$, let $B$ be a closed metric ball in $\mathcal{R}^n$ with the same volume as $A$. For every $\epsilon > 0$ let $A_\epsilon$ be the $\epsilon$-tube in $\mathcal{R}^n$ about $A$. Then

$$\mu_n(B_\epsilon) \leq \mu_n(A_\epsilon) \tag{2.7}$$

and consequentially,

$$\mu_{n-1}(\partial B) \leq \mu_{n-1}(\partial A). \tag{2.8}$$

*Proof.* The fact that Inequality 2.7 is sufficient to prove Inequality 2.8 is an immediate consequence of our definition of surface area. We need some addititional definititions. For any bounded subset $C \subset \mathcal{R}^n$ we let

$$r(C) = \min\{\rho; \exists x \in \mathcal{R}^n : C \subset \overline{B(x,\rho)}\}. \tag{2.9}$$

The function $r$ is continuous on the set of compact non-empty subsets of $\mathcal{R}^n$ with respect to the metric topology induced by the metric

$$\delta(C,D) = \min\{\epsilon; C \subset D_\epsilon, D \subset C_\epsilon\}. \tag{2.10}$$

Each bounded subset $C$ of $\mathcal{R}^n$ then has a circumdisk

$$\text{circ}(C) = \text{the disk with radius } r(C) \textit{ containing } C. \tag{2.11}$$

We define

$$\text{cent}(C) = \text{center of circ}(C). \tag{2.12}$$

Note that with respect to $\delta$, the volume functional $\mu_n$ is upper semi-continuous, ie.

$$\delta(C^k, C) \to 0 \Rightarrow \limsup_{k\to\infty} \mu_n(C_k) \leq \mu_n(C). \tag{2.13}$$

Let $\Gamma$ be a geodesic in $\mathcal{R}^n$. For each $x \in \Gamma$ let

$$H^x = \text{the totally geodesic submanifold perpendicular to } \Gamma \text{ at } x. \tag{2.14}$$

Note that the map $y \mapsto \mu_{n-1}(H^y)$ is upper semi-continuous.

For a compact subset $C$ of $\mathcal{R}^n$, for $x \in \Gamma$ we let

$$C^x = C \cap H^x \tag{2.15}$$

and let

$$\mathbf{D}^x(C) = \text{the disk in } H^x \text{centered at } x \text{ with } \mu_{n-1}(\mathbf{D}^x(C)) = \mu_{n-1}(C^x). \tag{2.16}$$

The set

$$\sigma_\Gamma C = \cup_{x\in\Gamma}\mathbf{D}^x_C \tag{2.17}$$

is called the (Steiner) symmetrization of $C$ with respect to $\Gamma$ (see Figure 2.7). It follows from the definition of Riemannian measure and the fact that the cut locus of a point is a set of measure zero (see Chavel, pp. 113, 134), or just Fubini's theorem, that $\mu_n(\sigma_\Gamma C) = \mu_n(C)$. A basic but central fact in the proof is that $\text{circ}(C)$ is invariant under symmetrization about geodesics that pass through $\text{cent}(C)$.

For the particular compact set $A$ given in the statement of the theorem, we put

$$M(A) = \{C \in \mathcal{R}^n; C \text{ closed}, \mu_n(C) = \mu_n(A) \text{ and } \forall\epsilon > 0 : \mu_n(C_\epsilon) \leq \mu_n(A_\epsilon)\}. \tag{2.18}$$

The assertion of the theorem is that disks with the same volume as $A$ are in $M(A)$ (see Inequality 2.7). The proof is broken into three main steps.

1. For all compact $A \in \mathcal{R}^n$, there is an element of $M(A)$ that is minimal for $r$.

2. Given any compact $A$ in $\mathcal{R}^n$ and geodesic $\Gamma$, $\sigma_\Gamma A \subset M(A)$.

3. For any compact $A \in \mathcal{R}^n$ which is not a disk, there exists a finite set $\{\Gamma_1, \ldots, \Gamma_k\}$ such that

$$r(\sigma_{\Gamma_k}\sigma_{\Gamma_{k-1}}\ldots\sigma_{\Gamma_1}A) < r(A).$$

By steps 2 and 3, an $r$-minimal element of $M(A)$ must be a disk. By step 1, an $r$-minimal element (which we may now fittingly call '$D$') exists.

These steps are carried out in the following paragraphs.

**1. Existence of $r$-minimal element.** It suffices to consider elements $C \in M(A)$ with $r(C) < r(A)$, and by an isometry we can restrict further to those elements $C$ with $\text{cent}(C) = \text{cent}(A)$; we will call the set of lower-radius, concentric† sets $m(A)$. With respect to the metric $\delta$, the set $m(A)$ is compact in the set of compact sets of $\mathcal{R}^n$ . We consider a sequence of such sets $C^k$ with $r(C^k)$ converging to the infimum of the '$r$'s associated with sets in $m(A)$. There is an associated subsequence which converges with respect to $\delta$ to a limit which we'll call $B$. We want to show that $B \in M(A)$.

For all $\eta > 0$, we trivially have $B \subset B_\eta$ and $B_\epsilon \subset B_{\eta+\epsilon}$, and hence for all $k$ large enough, if $\epsilon > 0$, we have $B_\epsilon \subset B^k_{\eta+\epsilon}$. Therefore since $B^k \in m(A)$ we have that

$$\mu_n(B_\epsilon) \leq \mu_n(B^k_{\eta+\epsilon}) \leq \mu_n(A_{\eta+\epsilon}). \tag{2.19}$$

Hence

$$\begin{aligned} \mu_n(B_\epsilon) &\leq \inf_\eta \mu_n(A_{\eta+\epsilon}) && (2.20)\\ &= \mu_n(\cap_{\eta>0} A_{\eta+\epsilon}) && (2.21)\\ &= \mu_n(A_\epsilon) && (2.22) \end{aligned}$$

where 2.22 is true because $A$ is compact. This shows that $\mu_n(B) \leq \mu_n(A)$. The upper semi-continuity of $\delta$ implies that

$$\mu_n \geq \limsup_{k\to\infty} \mu_n(B^k) = \mu_n(A), \tag{2.23}$$

and so we are done with the first step.

**2. Symmetrization reduces measure of tubular neighborhood (non-compact case).** We want to show that the symmetrization of $A$ is in $M(A)$. We need only show that

$$\mu_n((\sigma_\Gamma A)_\epsilon) \leq \mu_n(A_\epsilon).$$

†*I.e.* concircumcentric.

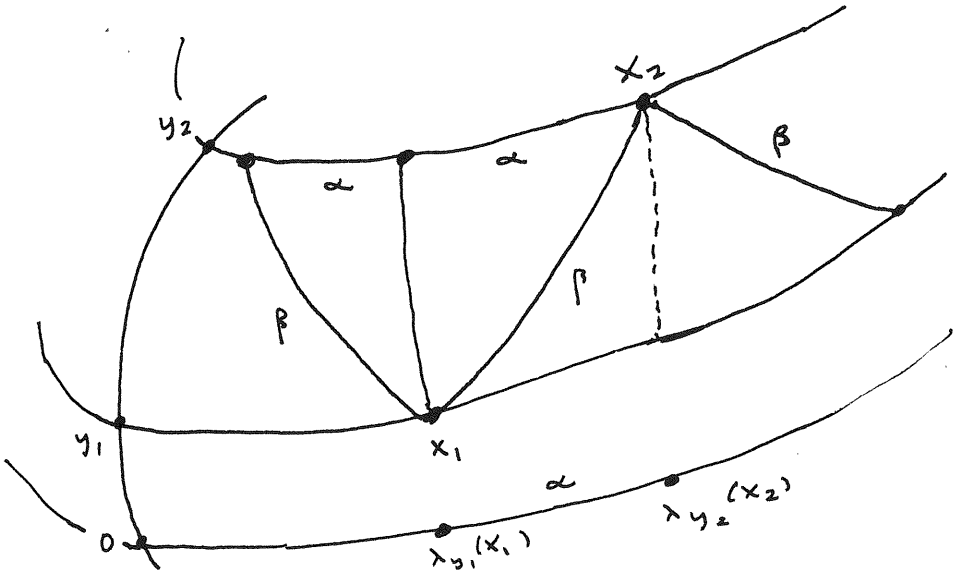

Figure 2.8: $\Psi(y_1, y_2, d(\lambda_{y_1}(x_1), \lambda_{y_2}(x_2)))$ gives the distance between $x_1$ and $x_2$.

Fix a point $o \in \Gamma$, and for any other point $y \in \Gamma$, let $\tau_y$ denote parallel translation along $\Gamma$ from $y$ to $o$. Recall that for every point $x \in \Gamma$ we are letting $H^x$ denote the totally geodesic subspace perpendicular to $\Gamma$ at $x$ (see Equation 2.14). We now define an isometry

$$\lambda_y : H^y \to H^o$$

by

$$\lambda_y = \exp_o t\cdot|_{\left(\frac{d\Gamma}{dt}|_{(\Gamma^{-1}(o))}\right)^\perp} \circ \tau_y \circ \left(\exp_y t\cdot|_{\left(\frac{d\Gamma}{dt}|_{(\Gamma^{-1}(y))}\right)^\perp}\right)^{-1}. \tag{2.24}$$

(This map makes sense because the inverse of $\exp_y$ maps points in the submanifold to tangent vectors; we then move these tangent vectors using $\tau_y$ and project them back to the manifold using $\exp_o$; it is clearly an isometry because all of the $(n-1)$-dimensional totally geodesic subspaces of $\mathcal{R}^n$ have the same metric properties.)

As illustrated in Figure 2.8, there is some function $\Psi : \Gamma \times \Gamma \times [0, \infty) \to \mathbf{R}$ such that for $x_1 \in H^{y_1}$, $x_2 \in H^{y_2}$ we have

$$d(x_1, x_2) = \Psi(y_1, y_2, d(\lambda_{y_1}(x_1), \lambda_{y_2}(x_2))). \tag{2.25}$$

Recall that for a general compact set $C \subset \mathcal{R}^n$ we are letting $C^x$ denote $C \cap H^x$. Equation 2.25 implies that if $y_1, y_2 \in \Gamma$ and $\epsilon > 0$ such that $d(y_1, y_2) \leq \epsilon$ then there is some number $\eta$, depending

on $y_1, y_2$ and $\epsilon$ such that if $Z \subset H^{y_1}$ then $(Z_\epsilon)^{y_2} = (\lambda_{y_2}^{-1} \circ \lambda_{y_1})((Z_\eta)^{y_1})$. (That is, we start with an $(n-1)$-dimensional subset $Z$ of $H^{y_1}$, thicken it in $\mathcal{R}^n$ by $\epsilon$ and then slice by $H^{y_2}$. The result is the same as thickening $Z$ by $\eta$ in $H^{y_1}$ and then projecting to $H^{y_2}$.)

Note that $d(y_1, y_2) > \epsilon$ implies that for any $(n-1)$-dimensional subset $Z$ of $H^{y_1}$ that $(Z_\epsilon)^{y_2} = \emptyset$. Therefore, given $\epsilon > 0$, and $y \in \Gamma$ we have

$$(A_\epsilon)^y = \bigcup_{\substack{z \in \Gamma \\ d(z,y)<\epsilon}} \lambda_y^{-1} \circ \lambda_z((A^z)_{\eta(z,y,\epsilon)}), \tag{2.26}$$

and of course we also have

$$((\sigma_\Gamma A)_\epsilon)^y = \bigcup_{\substack{z \in \Gamma \\ d(z,y)<\epsilon}} \lambda_y^{-1} \circ \lambda_z(((\sigma_\Gamma A)^z)_{\eta(z,y,\epsilon)}). \tag{2.27}$$

We have

$$\mu_{n-1}((A_\epsilon)^y) = \mu_{n-1}\left(\bigcup_{\substack{z \in \Gamma \\ d(z,y)<\epsilon}} \lambda_y^{-1} \circ \lambda_z((A^z)_{\eta(z,y,\epsilon)})\right) \tag{2.28}$$

$$\geq \sup_{\substack{z \in \Gamma \\ d(z,y)<\epsilon}} \mu_{n-1}(\lambda_z(A^z)_{\eta(z,y,\epsilon)}). \tag{2.29}$$

Replacing $A$ by $\sigma_\Gamma A$ in 2.28 and 2.29 yeilds equality, since $\lambda_y^{-1} \circ \lambda_z(((\sigma_\Gamma A)^z)_{\eta(z,y,\epsilon)})$ is an $(n-1)$-dimensional disk centered at $y$. Assuming that Theorem 2.1 is true in dimension $n-1$ means that

$$\mu_{n-1}(((\sigma_\Gamma A)^z)_{\eta(z,y,\epsilon)}) \leq \mu_{n-1}((A^z)_{\eta(z,y,\epsilon)})$$

and so we have

$$\mu_{n-1}(\lambda_z((\sigma_\Gamma A)^z)_{\eta(z,y,\epsilon)}) \leq \mu_{n-1}(\lambda_z((A^z)_{\eta(z,y,\epsilon)})) \tag{2.30}$$

for all $z \in \Gamma$, which implies

$$\mu_{n-1}(((\sigma_\Gamma A)_\epsilon)^y) = \sup_{z \in \Gamma : d(z,y)<\epsilon} \mu_{n-1}(\lambda_z((\sigma_\Gamma A)^z)_{\eta(z,y,\epsilon)}) \tag{2.31}$$

$$\leq \sup_{z \in \Gamma : d(z,y)<\epsilon} \mu_{n-1}(\lambda_z(A^z)_{\eta(z,y,\epsilon)}) \tag{2.32}$$

$$\leq \mu_{n-1}(A_\epsilon^y). \tag{2.33}$$

Therefore, all $y \in \Gamma$ are such that

$$\mu_{n-1}(((\sigma_\Gamma A)_\epsilon)^y) \leq \mu_{n-1}(A_\epsilon^y), \tag{2.34}$$

and so by further properties of the cut-locus (see Chavel [8], Equation (3.51) page 134) we have $\mu_n((\sigma_\Gamma A)_\epsilon) \leq \mu_n(A_\epsilon)$.

**2. Symmetrization reduces size of tubular neighborhood (Sphere case).** Let $A$ be a closed subset of $\mathbf{S}^{n-1}$ and let $\gamma$ be a half-circle on $\mathbf{S}^{n-1}$ joining $x_0$ with $-x_0$. Let $u$ be the midpoint of $\gamma$. Identify the sphere $\mathbf{S}_u^{n-2}$ (the equator) with $\mathbf{S}^{n-2}$ (this preserves measure and distances).

For every $y \in \gamma$ ($y \neq \pm x_0$) we define a mapping $\tau_y$ from $\mathbf{S}_y^{n-2}$ onto $\mathbf{S}_u^{n-2} = \mathbf{S}^{n-2}$ by projecting along the meridians (that is, for $x \in \mathbf{S}_y^{n-2}$, $\tau_y(x)$ is the point on $\mathbf{S}_u^{n-2}$ which belongs to the half circle joining $x_0, x$, and $-x_0$).

There is a function $f$ such that if $x_1 \in \mathbf{S}_{y_1}^{n-2}$ and $x_2 \in \mathbf{S}_{y_2}^{n-2}$ then

$$d(x_1, x_2) = f(y_1, y_2, d(\tau_{y_1}(x_1), \tau_{y_2}(x_2))). \tag{2.35}$$

Hence for every $y_1, y_2 \in \gamma$ and $\epsilon > 0$ such that $d(y_1, y_1) \leq \epsilon$, there is an $\eta = \eta(y_1, y_2, \epsilon) \geq 0$ such that every subset $C \subset \mathbf{S}_{y_1}^{n-2}$ has the property that

$$C_\epsilon \cap \mathbf{S}_{y_2}^{n-2} = \tau_{y_2}^{-1}((\tau_{y_1} C)_{\eta(y_1, y_2, \epsilon)}).$$

(If $d(y_1, y_2) > \epsilon$ then $C_\epsilon \cap \mathbf{S}_{y_2}^{n-2} = \emptyset$.)

Hence for every $\epsilon > 0$ and $y \in \gamma, y \neq \pm x_0$,

$$\tau_y((A_\epsilon^y)) = \cup_{z \in \gamma, d(z,y) \leq \epsilon} (\tau_z A^z)_{\eta(z,y,\epsilon)} \tag{2.36}$$

Now let $B = \sigma_\gamma A$. We have automatically that

$$\tau_y((B_\epsilon^y)) = \cup_{z \in \gamma, d(z,y) \leq \epsilon} (\tau_z B^z)_{\eta(z,y,\epsilon)} \tag{2.37}$$

For every $z \in \gamma$ the set $\tau_z B^z$ is by definition a cap in $\mathbf{S}^{n-1}$ such that $\mu_{n-2}(\tau_z B^z) = \mu_{n-2}(\tau_z A^z)$.

By the induction hypothesis (the theorem for $n-1$) we get that

$$\mu_{n-2}((\tau_z B^z)_{\eta(z,y,\epsilon)}) \leq \mu_{n-2}((\tau_z A^z)_{\eta(z,y,\epsilon)}) \tag{2.38}$$

for all 'admissable' $y, z, \epsilon$. Since all the sets appearing in the union on the right-hand side of Equation 2.37 are caps with the same center (*i.e.* $u$) we get by combining our equations that

$$\begin{aligned} \mu_{n-2}(\tau_y((B_\epsilon)^y)) &= \sup_{z\in\gamma, d(z,y)\leq\epsilon} \mu_{n-2}((\tau_z B^z)_{\eta(z,y,\epsilon)}) && (2.39)\\ &\leq \sup_{z\in\gamma, d(z,y)\leq\epsilon} \mu_{n-2}((\tau_z A^z)_{\eta(z,y,\epsilon)}) && (2.40)\\ &\leq \mu_{n-2}((\tau_y A^y)). && (2.41) \end{aligned}$$

So we have for every $y \neq \pm x_0$ in $\gamma$ that

$$\mu_{n-2,y}((B_\epsilon^y)) \leq \mu_{n-2,y}((A_\epsilon)^y), \tag{2.42}$$

and by Fubini's theorem, this implies that $\mu_{n-1}(B_\epsilon) \leq \mu_{n-1}(A_\epsilon)$.

**3. Repeated symmetrization reduces radius.** We want to show that we can reduce $r$ by repeated symmetrization. So, suppose $A$ is not a disk. We note that symmetrization with respect to a geodesic $\Gamma$ through $\mathrm{cent}(A)$ maps $\mathrm{circ}(A)$ isometrically onto itself. Since $\sigma_\Gamma$ pulls $A$ off of the boundary and towards $\Gamma$ whenever there are gaps in $A \cap H^x$ $\sigma_\Gamma(A)$ (where we recenter[‡] $\sigma_\Gamma(A)$ on $\mathrm{cent}(A)$ if necessary) can not contain all of $\partial(\mathrm{circ}(A))$. We will show that by successive symmetrizations, we can reduce the intersection with the boundary of $\mathrm{circ}(A)$ to nothing, and so reduce $r$.

If $B \subset \mathrm{circ}(A)$, $B$ closed, and $x \in \partial(\mathrm{circ}(A)) \setminus B$ then $x \notin \sigma_\Gamma(B)$.

If $B \subset \mathrm{circ}(A)$, $B$ closed, and $C$ is subset of $\partial(\mathrm{circ}(A))$ open with respect to the metric induced by $d$ such that $C \cap B = \emptyset$, then since $C$ is open it contains a spherical cap subtended by some

[‡]*I.e.* recircumcenter

angle $\alpha > 0$. If $\alpha > \pi$ then $C$ contains a pair of antipodal points. Symmetrizing with respect to the geodesic determined by this pair of points finishes the argument If $\alpha < \pi$ then there is some $\Gamma$ such that there exists some relatively open subset $C'$ of $\partial(\mathrm{circ}(A))$ which is disjoint from $\sigma_\Gamma(A)$ and subtends an angle $3\alpha/2$. This then is enough. QEF

## 2.3 Existence and regularity

**Charter** We should understand the known results on the existence and regularity of solutions to area minimization problems with multiple volume constraints.

### 2.3.1 Generalized manifolds

Geometric measure theory works with classes of geometric sets much more general than the class of manifolds. These generalizations were developed, it seems, for two main reasons: (1) Physics, since many phenomena exhibit behavior that is not smooth eg. bubble clusters, black holes, crystals, and so on; (2) Mathematics, since generalized manifolds arise naturally, in much the same way as generalized functions (*i.e.*, distributions). Insofar as (1) and (2) are related (and it happily turns out that they are) we do a disservice to both if we do not note that the main place these extended ideas of manifolds are likely to be interesting is in mathematical physics, where they appear as solutions to differential equations (eg. the variational problems studied in this thesis).

The idea is to use quite general geometrical objects at first and then show that when further natural constraints are imposed (eg. physically motivated ones), the only objects that satisfy the constraints are actually the nice (eg. smooth almost everywhere) things that we were expecting to see. This allows us to do away with potentially very dissatisfying hypotheses, such as 'if $A$ has smooth boundary' (cf. Theorem 2.1 and Definition 2.8). This does not come cheaply. *The sequence of definitions that follows assumes a basic familiarity with vector space duals, differential forms, and*

*measures, as might be gained by reading the appendices.*

**Definition 2.11.** We will denote by $D^m$ the space of $C^\infty$ differential $m$-forms on $\mathbf{R}^n$ with compact support.

**Definition 2.12.** We let $D_m$ denote the space of linear functionals on $D^m$ endowed with the weak topology, *i.e.* open sets are defined so that if $\{T_j\}$ is a sequence in $D_m$, it converges to $T \in D_m$ if and only if $T_j\varphi \to T\varphi$ for all $\varphi \in D^m$. An element of $D_m$ is called an *$m$-dimensional current*.

**Definition 2.13.** We define the boundary of current by duality, that is, if $T$ is an $m$-dimensional current, $\partial T$ is an $(m-1)$-dimensional current defined by $(\partial T)(\omega) = T(d\omega)$ for all $(m-1)$-forms $\omega$.

**Definition 2.14.** We also define the pushforward of a rectifiable current using duality, so that that if $T$ is an $m$-dimensional current and $\varphi : \mathbf{R}^n \to \mathbf{R}^n$ then $\varphi_* T$ is an $m$-dimensional current defined by $\varphi_* T(\omega) = T(\varphi^* \omega)$ for all $m$-forms $\omega$.

*Remark 2.6.* We might have suspectated that $\varphi_*$ and $\varphi^*$ would turn out to be dual operations from the beginning. Definition 2.14 makes this precise.

**Definition 2.15.** For $m \leq n$, we define the *$m$-dimensional Hausdorff measure of $A \subset \mathbf{R}^n$*, denoted $\mathcal{H}^m(A)$, in terms of covering classes $\{\mathcal{C}_\delta\}_{\delta>0}$ with the property that $S_\delta \in \mathcal{C}_\delta$ implies $S_\delta$ is countable and if $S_\delta = \{S_j \subset \mathbf{R}^n\}_{j=1}^n$ then $A \subset \cup_{j=1}^\infty S_j$ and every $S_j$ has $r(S_j) < \delta$, where $r$ is the circumradius of $S_j$, defined by Equation 2.9. Letting $\alpha_m$ denote the Lebesgue measure of the closed unit ball in $\mathbf{R}^m$, the Hausdorff measure of $A$ is then given by

$$\mathcal{H}^m(A) = \lim_{\delta \to 0^+} \inf_{S_\delta \in \mathcal{C}_\delta} \sum_{j=1}^{\infty} \alpha_m (r(S_j))^m \tag{2.43}$$

where the limit is seen to exist (in $\mathbf{R} \cup \infty$) because the infima do not decrease as $\delta$ decreases.

**Definition 2.16.** We say that a set $A \subset \mathbf{R}^n$ is an *$m$-dimensional rectifiable set* if $A$ is $\mathcal{H}^m$-measurable, $\mathcal{H}^m(A) < \infty$, and $\mathcal{H}^m$-almost all of $A$ is contained in the image of some countable collection of Lipschitz maps from $\mathbf{R}^m$ to $\mathbf{R}^n$.

*Remark 2.7.* The set of smooth $m$-manifolds is clearly inside the set of rectifiable sets since by paracompactness (and the rest of the definition) a smooth manifold is contained it the image of some countable collection of smooth maps from $\mathbf{R}^m$.

Tangent planes to a rectifiable set are defined $\mathcal{H}^m$-almost everywhere. We can choose an orientation for each tangent plane, and we then write its (now, ordered) basis of tangent vectors as the $m$-vector $\Xi = (\mathbf{x}_1, \ldots, \mathbf{x}_m)$.

**Definition 2.17.** An *$m$-dimensional rectifiable current* is an element $\mathcal{S}$ of $D_m$ that has compact support in $D^m$ and that is associated with a rectifiable set $S$ with ordered basis of tangent vectors $\Xi$ in the sense that the action of $\mathcal{S}$ on $\omega \in D^m$ is given by

$$\mathcal{S}\omega = \int_{\{x \in S\}} \langle \omega(x), \Xi(x) \rangle \, d\mathcal{H}^m.$$

If $\mu : S \to \mathbb{Z}$, we may define

$$\mathcal{S}\omega = \int_{\{x \in S\}} \langle \omega(x), \Xi(x) \rangle \mu(x) \, d\mathcal{H}^m;$$

we then say that $\mathcal{S}$ has *multiplicity* $\mu$.

*Remark 2.8.* The general idea is to integrate some $m$-section of the $m$-tangent bundle over the underlying set. It almost goes without saying that these ideas work very naturally for the set of smooth orientable manifolds, so that we find that set sitting inside of the set of rectifiable currents. In general, if the underlying set we are working with does not admit some kind of global orientation, there could be trouble. Note that by Stokes' Theorem, the definition of boundary given above corresponds to the usual definition of boundary in the case of a rectifiable current that is associated to a smooth oriented manifold with boundary.

It does not necessarily have to be the case that the boundary of a rectifiable current (Definition 2.13) is again a rectifiable current. When this is the case give the current a special name.

**Definition 2.18.** An *integral current* $T$ is a rectifiable current whose boundary $\partial T$ is also a rectifiable current.

**Definition 2.19.** A *locally integral current* $T$ is an element of $D_m$ such that for all $x \in \mathbf{R}^n$ there is some integral current $S$ such that $x \notin \text{supp}(T - S)$.

**Definition 2.20.** We define the *mass norm* (actually semi-norm) on $D_m$ in terms of the comass norm on $m$-forms (Definition C.24) by

$$\mathbf{M}(T) = \sup_{\omega \in D^m} \{T\omega; \sup_{x \in \mathbf{R}^n} \{\text{comass}(\omega(x))\} \leq 1\}.$$

We can compute the mass norm, for example, of the boundaries of bubble cluster components.

**Definition 2.21.** A subset $S$ of $\mathbf{R}^n$ is an $(\mathbf{M}, 0, \delta)$-*minimal set (with respect to the null set)* if it is bounded and any Lipschitz deformation $\Phi$ of $\mathbf{R}^n$ that is equal to the identity outside of some $\delta$-ball has the property that $\mathcal{H}^m(S) \leq \mathcal{H}^m(\Phi(S))$.

**Definition 2.22.** We may relax the previous definition and talk about $(\mathbf{M}, \epsilon, \delta)$-*minimal sets (with respect to the null set)*, where $\epsilon$ is some function of the form $\epsilon(r) = Cr^\alpha$ and the condition of the previous definition becomes $\mathcal{H}^m(S) \leq (1 + \epsilon(r))\mathcal{H}^m(\Phi(S))$ for all $r < \delta$.

*Remark 2.9.* $(\mathbf{M}, \epsilon, \delta)$-minimal sets are *rectifiable* [25] and have other nice properties.

### 2.3.2 Soap bubble clusters

The statements of the theorems are as follows:

**Theorem 2.2 ('Existence of compact minimizing bubble clusters').** In $\mathcal{R}^n$, given volumes $v_1, ..., v_m > 0$, there is a boundary mass-minimizing rectifable current comprised of bounded regions $V^i$ with volumes $v_i$.

This theorem was proved in the more general context of $(\mathbf{M}, \epsilon, \delta)$-minimal sets (which are also rectifiable sets, and so rectifiable currents) by Almgren [25]. The theorem motivates the following definition:

**Definition 2.23.** A *bubble cluster* is a disjoint union of bounded $n$-dimensional locally integral currents of multiplicty 1.

If we denote the complement of the cluster $C = \sqcup_{i=1}^{m} V^i$ by $V^0$, there is a convenient expression for the surface area in terms of the mass norm,

$$\text{Area}(C) = \frac{1}{2}\sum_{i=0}^{m} \mathbf{M}(\partial V^i). \tag{2.44}$$

In [25], Almgren also proved a basic regularity result.

**Theorem 2.3 ('Almgren Regularity').** A boundary-mass minimizing bubble cluster is bounded by $C^{1,\alpha}$ surfaces almost everywhere.

Note that where the surfaces are regular, a classical variational argument yeilds that they have constant mean curvature. Almgren's result been improved upon to give a more geometrical description of minimizers, with the first and best results in three dimensions by Taylor.

**Theorem 2.4 ('Taylor Regularity').** A soap bubble cluster in $\mathcal{R}^3$ consists of real analytic constant-mean curvature surfaces meeting smoothly in threes at one hundred and twenty degrees along smooth curves, which in turn meet in fours at angles of $\cos^{-1}(-1/3) \approx 109°$.

The curves described in Taylor's regularity theorem are called *singular curves*. The points at which these curves meet are *singular points*.

Taylors' proof is in two pieces; the Euclidean case in [53] and a generalization in [54]. Both are increadibly difficult to read. The singular curves were only proved to be $C^{1,\alpha}$ by Taylor; the analyticity came later; see Morgan [34] for a more complete overview of the history and proof. Morgan points out that this result has been partially extended to higher dimensions.

**Theorem 2.5 ('White's extension', unpublished).** Soap bubble clusters in $\mathbf{R}^n$ consist of smooth constant mean curvature hypersurfaces meeting in threes at one hundred and twenty degrees along smooth $(n-2)$-dimensional hypersurfaces, which in turn meet in an $(n-4)$-dimensional set.

*Remark 2.10.* Theorem 2.2 holds in any smooth Riemanian manifold with compact quotient by the isometry group. (As far as I know, this statement is a 'folk theorem'; the idea behind it it that we can pull all the pieces of a minimizer into some compact set where the general ideas of the theorems above can be applied.) It need not hold otherwise – for example, if there is a sequence of bumps with ever-increasing curvature headed off to infinity, any candidate minimizer could be improved upon by moving it to a different bump. The exact statement by Taylor is that the same results hold in a manifold with Hölder continuously differentiable metric is; a discussion of the relationship of these two criteria would take us outside of the scope of this thesis.

**Pressure and curvature.** One of the most important tools that we can use to study bubble clusters is a physically motivated condition, namely that pressures have to equilibrate. We use the phrase 'pressures add' as short-hand for the longer phrase: the sum of the pressure differences around a singular curve or vertex is zero. This, combined with the fact that pressure difference across walls is proportional to curvature, gives us a useful geometrical tool. A simple proof that pressure is proportional to curvature follows, based on a letter from Miguel Carrión Álvarez.

The basic principle of statics is that energy is minimized at equilibrium. In our case, surface tension is assumed to be constant throughout the whole system, and we have

$$\text{energy} = (\text{surface tension}) * (\text{total area}).$$

Work is the change in energy produced by motion. For example,

$$\text{work} = \text{torque} * (\text{angle rotated})$$

$$\text{work} = \text{force} * \text{displacement}.$$

By definition,

$$\text{pressure} = \text{force}/\text{area}.$$

Since we are in equilibrium the pressure *difference* across a wall

$$\text{pressure}_1 - \text{pressure}_2 = (\text{force}_1 - \text{force}_2)/\text{area}$$

has to be equal to

$$(\text{surface tension})/\text{area}.$$

Hence, if a bubble cluster changes its shape slightly, we have

$$\begin{aligned} \text{work} &= (\text{surface tension}) * (\text{change in area}) \\ &= (\text{pressure difference}) * (\text{change in volume}) \end{aligned}$$

and so

$$(\text{pressure difference}) = (\text{surface tension}) * (\text{area change})/(\text{volume change}).$$

From the appendix, we have

$$(\text{area change})/(\text{volume change}) = (\text{mean curvature})$$

whence,

$$(\text{pressure difference}) = (\text{surface tension}) * (\text{mean curvature}).$$

The fact that pressure is higher for smaller volumes (and so smaller bubbles will curve into larger neighbors) is an experimental observation – made, for example, by Robert Boyle in the 1600's. The above argument provides geometrical intuition for this (smaller things should have higher curvature) but not quite a proof.

# Chapter 3

# dbs in ccsfs

**Charter** The known results on double bubbles in constant curvature space forms are to be presented here. (This chapter is based on the results of Michael Hutchings [22] and his collaborators [23], and others who have worked subsequently with these results ([10], [41].)

In the previous two chapters, we became familiar with the geometry of $\mathcal{R}^n$. We studied single bubbles and proved that metric balls give the least perimeter enclosure of a given volume. For the double bubble problem in $\mathcal{R}^n$, the conjectured minimizer is more complicated; it is especially complicated in the negative curvature case. Figure 2.5 and the surrounding discussion motivates the following definition:

**Definition 3.1.** A *hypersphere-like submanifold* of $\mathcal{R}^n$ is a sphere in the positive or zero curvature cases, and a sphere, a horosphere, or a hyposphere in the negative curvature case.

**Lemma 3.1.** For prescribed volumes $v$ and $w$, there is a unique double bubble in $\mathcal{R}^n$, up to an isometry, that consists of three pieces of hypersphere-like submanifolds meeting at 120°. The outer caps are always pieces of spheres. This unique double bubble is called a *standard double bubble.*

To prove this lemma, one has to consider hypersphere-like submanifolds with all of the possible

curvatures and show that sticking them together at 120° yields all the possible volumes exactly once.

**Conjecture 3.1 (double bubble conjecture for $\mathcal{R}^n$).** The least-surface area way to enclose and separate two given volumes in $\mathcal{R}^n$ is the standard double bubble.

The results of this chapter grew up mainly in the context of the double bubble problem it $\mathbf{R}^n$, where the double bubble conjecture is known to be true for dimensions two [24], three [23], and four, and for some volumes in high dimensions [41]. However the conjecture has been thought of in the context of $\mathcal{R}^n$ for a long time.

Michael Hutchings [22] produced two key simplications of the problem in this general setting. The first simplification applies ideas of symmetrization to show that a non-standard minimizer must be bounded by a surface of revolution. This parallels the symmetrization techniques used in the proof of the single bubble problem in Chapter 2. Once we have this rotational symmetry the geometry becomes simple enough that we might hope to characterize non-standard competitors. The primary question then is, exactly how many regions can a minimizing bubble have? The second key simplification is an explicit bound on the number of components of each region in terms of the volumes. This makes a complete characterization possible. Indeed if the bound tells us that the largest of the two regions is connected, the a variational argument developed in the $\mathbf{R}^3$ by Hutchings, Morgan, Ritoré and Ros, successfully applied in the $\mathbf{R}^4$ version of the problem by Reichardt *et al.* and revised to work in $\mathbf{S}^n$ and $\mathbf{H}^n$ by Cotton and Freeman [10] can be applied to shows the instability of all remaining non-standard competitors. The two key simplifications of Hutchings and the instability argument for constant curvature space forms will be described in this chapter.

## 3.1 Hutchings structure theory

Hutchings proved many results for $m$ prescribed volumes. We need only two, but will do things in the general language when possible, because usually when it is possible it is also usually no harder.

**Definition 3.2.** We define the *least-area function* or *isoperimetric profile* of a given manifold $M$ to be the map that takes a given volume to the surface area of a least-area enclosure in the space that contains the given volume. We denote this function by $I_M$.

More generally, we define the *m-volume least-area function* to be the map that takes $m$ given volumes to the surface area of a least-area enclosure in the space that contains these volumes in separate chambers. We denote this function by $I_M^m$.

We are especially interested in the *two-volume least-area function*, which we denote by the special symbol $\mathit{\Pi}_M$.

We frequently will drop the subscripts of these maps when there is no chance of this making things confusing.

*Remark 3.1.* The isoperimetric profile is a primative of mean curvature for minimizers, *i.e.*,

$$dI(x)/dx = dA_{\text{minimizer}}(x)/dx = H_{\text{minimizer}}(x).$$

This is in fact a proof if you accept the second equality. The reason for that the equality is a simple variational argument (see [33] p. 15).

### 3.1.1 Symmetry

We saw in Chapter 2 how important symmetry was for solving the isoperimetric problem in constant curvature space forms. Symmetry is just as important for the double bubble problem, even though it is weaker (minimizing double bubbles are not spherically symmetric) and does not finish the job. *For double bubbles, the central symmetry result is that if $n \geq 3$ any area-minimizing double bubble in $\mathbf{R}^n$, $\mathbf{S}^n$ or $\mathbf{H}^n$ is symmetric about some line.* This is a corollary to the broader-reaching

**Theorem 3.1 (Symmetry Theorem ).** Let $B$ be a minimal enclosure of $m$ volumes in $\mathbf{R}^n$. If $m$ is less than or equal to $n-1$ then $B$ is symmetric about some $m-1$ plane.

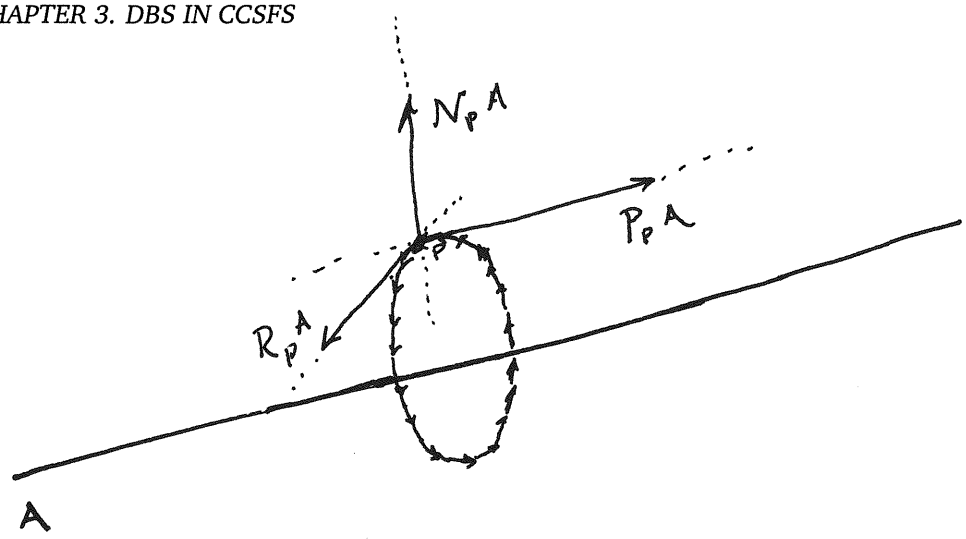

Figure 3.1: Hutchings' decomposition of $T_p(\mathbf{R}^3 \setminus A)$.

Hutchings proves Theorem 3.1 in a series of lemmas. We will do the same, after introducing some notation.

In the statement of the theorem and in all that follows, $B$ is taken to be an $n$-dimensional rectifiable current made up of a disjoint collection of $n$-dimensional regions $V^i$, such that $V^i$ has volume $v_i$. Until we say otherwise, these regions may be broken into many disjoint components.

Since it is area-minimizing its boundary is mainly made up of smooth manifold points. We let $B_{\text{reg}}$ denote the set of smooth manifold points in the boundary of $B$.

**Definition 3.3.** Let $A$ be an affine subspace of $\mathbf{R}^n$ with $\dim A \leq n-2$. We decompose the tangent bundle of $\mathbf{R}^n \setminus A$ as follows:

$$T(\mathbf{R}^n \setminus A) = \mathcal{P}A \oplus \mathcal{N}A \oplus \mathcal{R}A, \tag{3.1}$$

where $\mathcal{P}A$ are vectors parallel to $A$, $\mathcal{N}A$ are vectors normal to $A$, and $\mathcal{R}A$ are vectors that are perpendicular to both $\mathcal{P}A$ and $\mathcal{N}A$. It is important that we exclude $A$, because the decomposition degenerates at points in $A$ (see Figure 3.1). At a given point $p \in \mathbf{R}^n \setminus A$ we write the associated decomposition of the tangent space in the same way, so $T_p(\mathbf{R}^n \setminus A) = \mathcal{P}_pA \oplus \mathcal{N}_pA \oplus \mathcal{R}_pA$.

*Remark 3.2.* The case in which $A$ is a line in $\mathbf{R}^3$ is illustrated in Figure 3.1. Here it is clear that $\mathcal{R}A$

are vectors taken from vectorfields that determine a rotation about $A$. It works the same way in higher dimensions. For example, if $A$ is a $2-$plane in $\mathbf{R}^4$ then $\mathcal{P}_p A$ is two dimensional, $\mathcal{N}_p A$ is one dimensional, and so there is an extra dimension left over for $\mathcal{R}_p A$.

**Lemma 3.2 ('Infinitesimal Symmetry Implies Global Symmetry' ).** Let $B$ be a minimizing enclosure of $m$ volumes in $\mathbf{R}^n$, and let $A$ be an affine subspace of $\mathbf{R}^n$ with $\dim(A) \leq n-2$. Suppose that for almost all $p \in B_{\text{reg}} \setminus A$ that we have $\mathcal{R}_p A \subset T_p B$. Then $B$ is symmetric about $A$.

*Proof.* Since $\dim A \leq n-2$, an object mapped to itself invariantly under rotations about $A$ will also be mapped to itself invariantly under reflections about $A$.

Let $\varphi$ be a rotation about $A$. Our goal is to show that $\varphi_* \partial V^i = \partial V^i$ for all $i$. By the definition of the pushforward of a current (Definition 2.14), this means that the boundary of $V^i$ is fixed under rotation about $A$.

Associated to $\varphi$ is a one parameter group $\{\varphi_t\}$ of rotations about $A$ such that $\varphi = \varphi_1$. These induce a vector field $\mathcal{V}$ on $\mathbf{R}^n$. If $\omega$ is an $(n-1)$-form on $\mathbf{R}^n$,

$$\begin{aligned} \frac{d}{dt}\Big|_{t=0} \langle \partial V^i, \varphi_t^* \omega \rangle &= \langle \partial V^i, (d\iota(\mathcal{V}) + \iota(\mathcal{V})d)\omega \rangle && (3.2) \\ &= \langle \partial V^i, d\iota(\mathcal{V})\omega \rangle + \langle \partial V^i, \iota(\mathcal{V}) d\omega \rangle && (3.3) \\ &= \langle \partial V^i, \iota(\mathcal{V}) d\omega \rangle, && (3.4) \end{aligned}$$

where the equality between 3.3 and 3.4 is due to Stokes' theorem. If the members of this chain of equalities are equal to zero, then the value of the pairing is constant to first order at $t = 0$, and this implies that the pairing is constant for all $t$. If $\mathcal{V}(p) \in T_p B$, Equation 3.4 implies that for almost all $p \in B_{\text{reg}} \cap \partial V^i$ we have

$$\langle \iota_{\mathcal{V}} d\omega(p), \Xi(p) \rangle = 0, \tag{3.5}$$

where $\Xi(p)$ denotes the ordered basis of $T_p(\partial B)$. This shows that the members of 3.4 are equal to zero. Since $\mathcal{V}(p) \in \mathcal{R}_p A$ for all $p \notin A$ and $\mathcal{R}_p(A) \subset T_p B$ for almost all $p \in B_{\text{reg}}$ such that $p \notin A$, we

have

$$\langle \partial V^i, \omega \rangle = \langle \partial V^i, \varphi^* \omega \rangle \tag{3.6}$$

Since $\langle \partial V^i, \varphi^* \omega \rangle = \langle \varphi_* \partial V^i, \omega \rangle$ by definition, this completes the proof. QEF

**Lemma 3.3 (Bisectors Orthogonal ).** Let $B$ be a minimizing enclosure of $m$ volumes in $\mathbf{R}^n$, and let $H$ be a hyperplane that bisects all of the $V^i$. Then $H$ and $B_{\text{reg}}$ are orthogonal wherever they intersect.

*Proof.* Let $B_+$ and $B_-$ be the halves of $B$ on either side of $H$. Since $H$ bisects all of the regions, we can make a new cluster $\widehat{B_+}$, equal to the union of $B_+$ the reflection of $B_+$ across $H$. The regions $\widehat{V^i}$ that make up $\widehat{B_+}$ have the same volume as the $V^i$. Since $B$ is minimizing, $\text{area}(\widehat{B_+}) \geq \text{area}(B)$, so $\text{area}(B_+) \geq \text{area}(B_-)$. Similarly, $\text{area}(B_-) \geq \text{area}(B_+)$, hence they must be equal, and so we must have $\text{area}(\widehat{B_+}) = \text{area}(\widehat{B_-}) = \text{area}(B)$.

Hence, $\widehat{B_+}$ and $\text{area}(\widehat{B_-})$ are minimizing too. By regularity, the tangent spaces to the regular points of $B$ contained in $H$ are either orthogonal to or parallel to $H$.

The final step is to show that if $B$ is tangent to $H$ at a regular point then either $\widehat{B_+}$ or $\widehat{B_-}$ can be modified to decrease area. (This is enough because the tangent spaces will only be parallel to $H$ at points where $\widehat{B_+}$ is tangent to $H$ or at points where $\widehat{B_+}$ and $H$ do not intersect.)

Note that $\mathbf{R}^n$ can be parameterized by $H \times \mathbf{R}$. If $\mathbf{D}_p(r)$ is a closed ball of radius $r$ about $p \in H$ then $B$ is regular in $\mathbf{D}_p(r) \times [-\epsilon, \epsilon] \subset H \times \mathbf{R}$. Since $B$ is tangent to $H$ at $p$, chosing $r$ small enough to have

$$B \cap \partial(\mathbf{D}_p(r) \times [-\epsilon, \epsilon]) \subset (\partial \mathbf{D}_p(r) \times [-\epsilon, \epsilon])$$

for small $\epsilon$, and so that $\mathbf{D}_p(r) \times \{\pm\epsilon\}$ are in the same component of $\widehat{B_+}$, we remove $\widehat{B_+}$ from its intersection with $\mathbf{D}_p(r) \times [-\epsilon, \epsilon]$ and add back $\partial \mathbf{D}_p(r) \times [-\epsilon, \epsilon]$. This decreases area to the order of $r^{n-1}$, and changes the areas of $\widehat{V^i}$ of at most order $\epsilon r^{n-1}$.

By a standard first variation argument, we can restore the volumes by adjusting the cluster

elsewhere, with an area increase of at most order $\epsilon r^{n-1}$. This is smaller than the initial increase for $r$ sufficiently small. QEF

**Lemma 3.4 (Symmetry about intersections).** Let $B$ be a minimizing enclosure of $m$ volumes in $\mathbf{R}^n$. Let if $k > 1$ and $H_1, \ldots, H_k$ be mutually orthogonal hyperplanes. If $B$ is symmetric about each $H_i$ then $B$ is symmetric about $A = \cap_{i=1}^{k} H_i$.

*Proof.* $B$ maps to itself invariantly under reflection across each $H_i$, so also maps to itself invariantly under reflection across $A$. So every hyperplane containing $A$ bisects $V^1, \ldots, V^m$. Since $B_{\text{reg}}$ meets its bisectors orthogonally wherever they intersect, and the directions perpendicular to all of the $H_i$ are the directions of rotation about $A$, $B$ is symmetric about $A$, because infinitesimal symmetry implies global symmetry. QEF

**Lemma 3.5 ( Linear Algebra).** If $A_1$ and $A_2$ are affine subspaces of $\mathbf{R}^n$ with non-empty intersection, and $p \notin \text{span}(A_1, A_2)$, then $\mathcal{R}_p(A_1 \cap A_2) = \mathcal{R}_p A_1 \oplus \mathcal{R}_p A_2$

*Proof.* Any rotation fixing $A_1$ or $A_2$ fixes $A_1 \cap A_2$ so

$$\mathcal{R}_p(A_1 \cap A_2) \supset \mathcal{R}_p A_1 \oplus \mathcal{R}_p A_2.$$

If

$$\mathcal{R}_p(A_1 \cap A_2) \not\subseteq \mathcal{R}_p A_1 \oplus \mathcal{R}_p A_2,$$

then since

$$\dim \mathcal{R}_p A_1 \cap \mathcal{R}_p A_2 > n - \dim \text{span}(A_1, A_2) - 1,$$

and since

$$\mathcal{R}_p A_1 \cap \mathcal{R}_p A_2 = (\mathcal{P}_p A_1 \oplus \mathcal{P}_p A_2 \oplus \mathcal{N}_p A_1 \oplus \mathcal{N}_p A_2)^{\perp}$$

and, lastly, since

$$\dim(\mathcal{P}_p A_1 \oplus \mathcal{P}_p A_2) = \dim \text{span}(A_1, A_2),$$

we must have

$$\mathcal{N}_p A_1 \subset \mathcal{P}_p A_1 \oplus \mathcal{P}_p A_2.$$

Since $\mathcal{N}_p A_1$ is perpendicular to $\mathcal{P}_p A_1$ and $\mathcal{N}_p A_1 \subset \mathcal{P}_p A_2$, we must have $p \in \text{span}(A_1, A_2)$. This contradicts our assumption, so we have the claim. QEF

**Lemma 3.6 (Assembly, Euclidean case ).** Let $B$ be a minimizing enclosure of $m$ volumes in $\mathbf{R}^n$. Let $H$ be a hyperplane, and let $B_+$ and $B_-$ be the two symmetrizations of $B$ across $H$. Suppose that both $B_+$ and $B_-$ minimize area for the volumes they enclose. Let $A_+$ and $A_-$ be non-empty affine subspaces of $H$ of dimension at most $n-2$. If $B_\pm$ is symmetric about $A_\pm$ then $A_+ \cap A_- \neq \emptyset$ and $B$ is symmetric about $A_+ \cap A_-$.

*Proof.* First note thet $B \cap H$ is symmetric about $A_1$ and $A_2$ in $H$. We immediately rule out the possibility that $A_1 \cap A_2 = \emptyset$ since that would imply that $B$ is not compact, which contradicts its minimality. To prove symmetry it is enough to show that for $\mathcal{H}^{n-2}$-almost every $p \in B_{\text{reg}}$ such that $p$ is not in $A_1 \cap A_2$ that

$$\mathcal{R}_p(A_1 \cap A_2) \subset T_p B.$$

We first show that for almost every $p \in B \cap H$ that is not in $A_1 \cap A_2$ that each of $B$, $B_1$ and $B_2$ is regular at $p$ and for these '$p$'s we have $\mathcal{R}_p(A_1 \cap A_2) \subset T_p B$.

Since $B_i$ is regular almost everywhere and is symmetric about $A_i$ we know that almost every point in $(B_i \cap H) \setminus A_i$ is regular. Hence almost every point of $B \cap H$ that is not in either $A_1$ or $A_2$ is a regular point of both $B_1$ and $B_2$. Hence, by the Bisectors Orthogonal lemma (Lemma 3.3), we have that $B_1$ and $B_2$ are orthogonal to $H$ at each $p \in (B \cap H) \setminus (A_1 \cup A_2)$, and so a small ball $\mathbf{D}_\epsilon(p)$ meets only two of the '$V^i$'s that make up $B$, so $B$ is regular in $\mathbf{D}_\epsilon(p)$ except on a set of Hausdorff dimension at most $n-8$. From this it follows that almost every point in $(B \cap H) \setminus (A_1 \cup A_2)$ is a regular point for $B$, $B_1$ and $B_2$, as we wanted.

If $U$ is a regular neighborhood of such a point, then by uniqueness of analytic continuation we

have

$$U \cap B = U \cap B_1 = U \cap B_2.$$

Hence we have

$$\mathcal{R}_p(A_1), \mathcal{R}_p(A_2) \subset T_pB$$

for all $p \in U \setminus (A_1 \cup A_2)$. By the Linear Algebra lemma (Lemma 3.5), for all $p \in U \setminus H$ we have

$$\mathcal{R}_p(A_1 \cap A_2) \subset T_pB.$$

By continuity this holds for all $p \in U$.

Let $W_i$ be the closed half-space in which $B_i$ lies. Let $O_1$ be the union of orbits under rotation about $A_2$ whose intersection with $H$ is contained in $A_1$. Note that $O_1$ is half of a $k$-plane where $k \leq \dim(A_1) + 1$. Define $O_2$ similarly. By our work in the previous paragraph, for $\mathcal{H}^{n-1}$-almost every $p \in (B \cap W_1) \setminus O_2$ there is a rotation $\varphi$ about $A_1$ such that $\varphi(p) \in H$ and $\varphi(p)$ is a regular point for both $B$ and $B_1$, and furthermore, $\mathcal{R}_p(A_1 \cap A_2) \subset T_pB$. Since $B_1$ is invariant under $\varphi$ and $\varphi$ is a rotation about $A_1 \cap A_2$ it must be the case that $B$ is regular at $p$ and that $\mathcal{R}_p(A_1 \cap A_2) \subset T_pB$. Similar statements can be made for almost every $p \in (B \cap W_2) \setminus O_1$.

Now suppose that $p \in B_{\text{reg}} \cap O_i$. Either there is some regular neighborhood of $p$ contained in $O_i$ or $p$ is a limit of regular points of $B$ not in $O_i$ whose tangent spaces contain $\mathcal{R}_p(A_1 \cap A_2)$. In the latter case, continuity implies that $\mathcal{R}_p(A_1 \cap A_2) \subset T_pB$. In the former case, using the rotation invariance of both $B_1$ and $B_2$, we must have that the point in $\mathbf{R}^n$ on either side of $U$ lie in the same $V^i$ so $U$ can be removed to decrease area, contradicting the minimality of $B$. QEF

We can now prove our big theorem.

*Proof of Symmetry Theorem 3.1.* Since $B$ is compact, we can apply the ham sandwich theorem to produce a hyperplane $H_1$ that bisects all of the regions. By Assembly (Lemma 3.6) it is enough to show that each of the symmetrizations of $B$ across $H_1$ are symmetric about an $(m-1)$-plane in $H_1$. Let $B_1$ be one of the two possible symmetrizations. By the Borsuk-Ulam theorem, there is a

hyperplane $H_2$ orthogonal to $H_1$ that bisects all of the regions. By Assembly again, it is enough to show that each of the symmetrizations of $B_1$ across $H_2$ is symmetric about an $(m-1)$-plane in $H_1 \cap H_2$. We let $B_2$ be one of the two possible symmetrizations, and continue in this fashion until we have obtained hyperplanes $H_1, \ldots, H_{n-m+1}$ and a minimal cluster $B_{n-m+1}$. By Lemma 3.4 this cluster is symmetric about the $(m-1)$-plane $A = \cap H_i$. QEF

**Corollary 3.1.** Let $B$ be a minimal double bubble in $\mathbf{R}^n$ for $n \geq 3$ and let $H \subset \mathbf{R}^n$ be a hyperplane. If each symmetrization of $B$ across $H$ is area-minimizing for the volumes it encloses, then $B$ is symmetric about a line in $H$.

*Proof.* Use the symmetry theorem, starting with $H_1 = H$. QEF

### 3.1.2 Concavity of the least-area function

In this subsection, $I^m$ means the $m$-volume least-area function associated with a constant curvature space form of arbitrary dimension, and $\mathit{\Pi}$ means the 2-volume least-area function associated with a constant curvature space form of arbitrary dimension. The proof of the main theorem in this section (Theorem 3.2) relies on the symmetry we have in constant curvature space forms, and does not apply when there are more than two prescribed volumes. We begin with a simple lemma that does hold for any number of prescribed volumes.

**Lemma 3.7 ('Continuity').** For all $m$, $I^m$ is a continuous function.

*Proof.* Let $C$ be a least-area bubble cluster for volumes $v_1, \ldots, v_m$. Add a small round ball of radius $\epsilon$ somewhere away from the cluster, and say that it is now part of $V^1$. This increases the volume of $V^1$ by less than $\epsilon$ and increases surface area by less than $\epsilon$. This is an upper bound on the increase of surface area for a minimizing bubble cluster with volumes $v_1 + \epsilon, v_2, \ldots, v_m$, hence $I^m$ is continuous in the first component, and so by the same argument, in all.

QEF

**Theorem 3.2 ('Concavity').** $\Pi$ is a concave function in the sense that if $\mathbf{v}$ and $\mathbf{w}$ are two pairs of volumes, then for $t \in (0,1)$

$$\Pi(t\mathbf{v} + (1-t)\mathbf{w}) > t\Pi(\mathbf{v}) + (1-t)\Pi(\mathbf{w}).$$

*Proof.* We must prove that

$$\Pi(tv_1 + (1-t)w_1, tv_2 + (1-t)w_2) > t\Pi_(v_1, v_2) + (1-t)\Pi(w_1, w_2) \tag{3.7}$$

for all $t \in (0,1)$. For a contradiction, suppose not.

By continuity, the function $f$ defined by

$$f(t) = \Pi(tv_1 + (1-t)w_1, tv_2 + (1-t)w_2) - t\Pi(v_1, v_2) - (1-t)\Pi(w_1, w_2) \tag{3.8}$$

assumes a minimum on the interval [0,1] at some $t_0$.

Let $B$ be a minimizing cluster of two regions $V$ and $W$, with volumes

$$(v, w) = t_0(v_1, v_2) + (1-t_0)(w_1, w_2) = (t_0v_1 + (1-t_0)w_1, t_0v_2 + (1-t_0)w_2).$$

By the Symmetry Theorem (Theorem 3.1), $B$ is symmetric about some line $\ell$.

We can parameterize the set of oriented hyperplanes in $\mathbf{R}^n$ by $\mathbf{S}^{n-1} \times \mathbf{R}$, since each oriented hyperplane is determined by a normal direction and a distance from the origin in that direction.

We define a map $h_+$ from the set of oriented hyperplanes, so that given $H \in \mathbf{S}^{n-1} \times \mathbf{R}$ we let $H^+$ denote the upper half space determined by $H$, and we put

$$h_+(H) = (\mathrm{vol}(V \cap H^+), \mathrm{vol}(W \cap H^+)) \in \mathbf{R}^2$$

Since regularity implies $B$ is compact, $h_+$ is continuous.

By an isometry, we may assume 0 is in the line of symmetry $\ell$. We then choose $x \in \mathbf{S}^{n-1}$ perpendicular to $\ell$. The hyperplane determined by $(x, r) \in \mathbf{S}^{n-1} \times \mathbf{R}$ contains $\ell$ if and only if $r = 0$, and is parallel to $\ell$ otherwise. For all $r \in \mathbf{R}$ we have that

$$h_+(x, r) + h_+(x, -r) = (v, w), \tag{3.9}$$

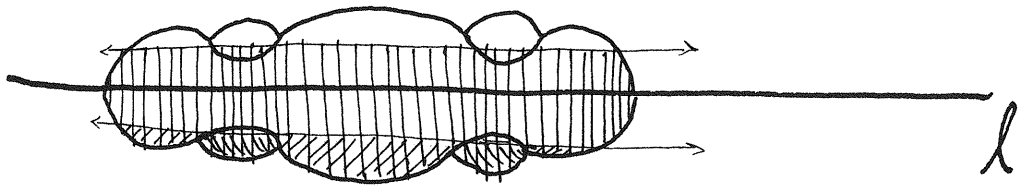

Figure 3.2: Cutting the bubble by oriented planes equidistant from $\ell$ gives all the volume.

since by symmetry the volumes that lie above $(x, r)$ are equal the volumes that lie below $(x, -r)$, hence the total ammount of volume collected by the two maps is equal to the total volume of the bubble (see Figure 3.2).

The line segment

$$\mathcal{K} = \left\{ \frac{t(v_1, v_2) + (1-t)(w_1, w_2)}{2}; t, 2t_0 - t \in (0,1) \right\} \tag{3.10}$$

in the volume plane has the property that either $h_+(x, r) \in \mathcal{K}$ for some $r \neq 0$ or $h_+(y \times [0, \infty)) \in \mathcal{K}$ whenever $y$ is close to $x$.

In both cases, there is a hyperplane $H_{x,t} \not\supseteq \ell$ such that

$$h_+ H_{x,t} = \frac{t(v_1, v_2) + (1-t)(w_1, w_2)}{2} \in \mathcal{K}.$$

Let

$$\begin{aligned} a_0 &= \text{area}(B \cap H_{x,t}) \\ a_+ &= \text{area}(B \cap H^+_{x,t}) \\ a_- &= \text{area}(B \cap H^-_{x,t}). \end{aligned}$$

Replacing $B \cap H^-_{x,t}$ with the reflection of $B \cap H^+_{x,t}$ across $H$, we find that

$$\begin{aligned} a_0 + 2a_+ &\geq \Pi(t(v_1, v_2) + (1-t)(w_1, w_2)) \\ &= f(t) + t\Pi(v_1, v_2) + (1-t)\Pi(w_1, w_2) \\ &\geq f(t_0) + t\Pi(v_1, v_2) + (1-t)\Pi(w_1, w_2) \\ &= \Pi(t_0(v_1, v_2) + (1-t_0)(w_1, w_2)) \\ &\quad + (t-t_0)\Pi(v_1, v_2) + (t_0 - t)\Pi(w_1, w_2). \end{aligned}$$

If we symmetrize in the other direction, we find that

$$\begin{aligned} a_0 + 2a_- &\geq \Pi(t_0(v_1, v_2) + (1-t_0)w) + ((2t_0 - t) - t_0)\Pi(v_1, v_2) \\ &\quad + (t_0 - (2t_0 - t))\Pi(w_1, w_2). \end{aligned}$$

Adding these, we get

$$2(a_0 + a_+ + a_-) \geq 2\Pi(t_0(v_1, v_2) + (1-t_0)(w_1, w_2)).$$

By the definition of the '$a$'s, this must be an equality, so each of the non-strict inequalities in the chain above must be equalities.

We can therefore conclude that each symmetrization of $B$ across $H_{x,t}$ is minimizing for the enclosed volumes.

By Corollary 3.1, $B$ is symmetric about some line $\ell' \subset H_{x,t}$. Since $B$ is compact, $\ell$ and $\ell'$ must intersect. But $\ell \neq \ell'$, so by applying the Assembly Lemma 3.6 to a hyperplane containing $\ell$ and $\ell'$ we get that $B$ is a union of concentric spheres. Then $B$ must contain only one sphere by regularity. *So $B$ encloses only one volume, and $(v_1, w_1)$ both lie on the same coordinate axis in $\mathbf{R}^2$.*

But $\Pi$ is strictly concave along any line through the origin, since (in general) by scaling

$$I^m_n(\lambda v_1, \ldots, \lambda v_m) = \lambda^{(n-1)/n} I^m_n(v_1, \ldots, v_m) \tag{3.11}$$

But this contradicts our assumption that $\Pi$ is not concave along this line.

This completes the proof in the case of $\mathbf{R}^n$. For the other spaces, we just have some comments: the proof for $\mathbf{H}^n$ is essentially the same, the only significant thing that one must check is that $I_{\mathbf{H}^n}$ is concave and this is very easy (see Lemma 3.8 in the next section); the theorem for $\mathbf{S}^n$ is a straightforward rewording of the theorem for $\mathbf{R}^n$– some things to note for the *proof* are (1) oriented hyperplanes in $\mathbf{S}^n$ are parameterized by $\mathbf{S}^n$, (2) instead of looking at paths of the form $h_+(x \times [0, \infty))$, we look at images of $h_+$ under geodesics, and (3) we have strict concavity along the edge of the simplex $\{v_1 + v_2 + v_3 = \text{vol}(\mathbf{S}^n)\}$ because in a minimal sphere dividing $\mathbf{S}^n$ into two equal volumes, the pressure difference between the two regions decreases as two of the volumes become.

QEF

### 3.1.3 Connectivity (component bound)

**Lemma 3.8 ('Ratio of area to volume is decreasing for spheres' ).** In $\mathbf{R}^n$, $\mathbf{S}^n$, and $\mathbf{H}^n$, $\frac{I(x)}{x}$ is decreasing in $x$.

*Proof.* We use the following standard formulas for area and volume as functions of radius ($\alpha_n$ is again the Lebesgue measure of the unit ball in $\mathbf{R}^n$):

| | $\mathbf{R}^n$ | $\mathbf{S}^n$ | $\mathbf{H}^n$ |
|---|---|---|---|
| $A_{\text{sphere}}$ | $n\alpha_n r^n$ | $n\alpha_n \sin^{n-1} r$ | $n\alpha_n \sinh^{n-1} r$ |

Working from the appendix on variational calculus, we have

$$H_{\text{sphere}} = \frac{dA_{\text{sphere}}}{dV_{\text{sphere}}} = \frac{dA_{\text{sphere}}(r)/dr}{dV_{\text{sphere}}(r)/dr} = \frac{A'_{\text{sphere}}(r)}{A_{\text{sphere}}(r)},$$

By a very easy computation we get

| | $\mathbf{R}^n$ | $\mathbf{S}^n$ | $\mathbf{H}^n$ |
|---|---|---|---|
| $H_{\text{sphere}}$ | $n/r$ | $(n-1)\cot(r)$ | $(n-1)\coth(r)$ |

A glance at the graphs of these functions (on the appropriate domains) proves that mean curvature of spheres is a decreasing function of radius in each space. Since $I(x)$ is a primative of mean curvature,

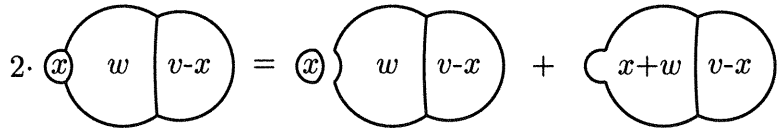

Figure 3.3: Decomposition of a double bubble in which $V$ has a component of volume $x$

this proves that $I$ is concave. From this we see directly that the ratio $I(x)/x$ is decreasing, since if $I$ is is not decreasing, its slope is. QEF

**Lemma 3.9 ('Basic Estimate').** Consider a minimal enclosure of volumes $v$ and $w$ in $\mathcal{R}^n$. Suppose that the region $V$ has a connected component with volume $x$. Then

$$2\Pi(v,w) \geq I(w) + \frac{v}{x}I(x) + I(v+w).$$

*Proof.* From Figure 3.3,

$$2\Pi(v,w) \geq \Pi(v-x,w) + I(x) + \Pi(v-x,w+x). \tag{3.12}$$

From Concavity (Theorem 3.2), with $v_1 = 0, v_2 = v+w, w_1 = v, w_2 = w$ and $t = x/v$ in Inequality 3.7, we get

$$\Pi(v-x,w+x) \geq \frac{v-x}{v}\Pi(v,w) + \frac{x}{v}I(v+w),$$

and again with $v_1 = 0, v_2 = w, w_1 = v, w_2 = w$ and $t = x/v$ we get

$$\Pi(v-x,w) \geq \frac{v-x}{v}\Pi(v,w) + \frac{x}{v}I(w).$$

Substitution of these bounds into Inequality 3.12 gives our result, upon making the following rearrangements:

$$\begin{aligned} 2\Pi(v,w) &\geq \frac{v-x}{v}\Pi(v,w) + \frac{x}{v}I(w) + I(w)\frac{v-x}{v}\Pi(v,w) + \frac{x}{v}I(v+w) \\ &= 2\Pi(v,w) - 2\frac{x}{v}\Pi(v,w) + \frac{x}{v}I(w) + I(x) + \frac{x}{v}I(v+w) \\ \Rightarrow 2\frac{x}{v}\Pi(v,w) &\geq \frac{x}{v}I(w) + I(x) + \frac{x}{v}I(v+w). \end{aligned}$$

Now divide through by $x/v$. QEF

*Remark 3.3.* The theorem we just proved and the following corollaries work in any space where $I\!I$ is concave.

**Corollary 3.2.** In a double bubble enclosing and separating the pair of volumes $(v, w)$ where $(v, w)$ satisfies

$$F(v,w) = 2I\left(\frac{v}{2}\right) + I(w) + I(v+w) - 2I\!I(v,w) > 0, \tag{3.13}$$

$V$ is connected.

*Proof.* Suppose Inequality 3.13 holds. Let the *smallest* component of the region $V$ be $V_1$. By concavity of $I\!I$, (Theorem 3.2) we can apply the Basic Estimate (Lemma 3.9). This yields

$$\frac{v}{v_1} I(v_1) \leq 2I\!I(v,w) - I(w) - I(v+w). \tag{3.14}$$

Since the left hand side of this inequality is decreasing in $v_1 \leq v$ by Lemma 3.8, if $v_1 \leq v/2$, we have

$$\frac{v}{v/2} I(v_1) \leq 2I\!I(v,w) - I(w) - I(v+w) \tag{3.15}$$

*i.e.*

$$2I(v_1) \leq 2I\!I(v,w) - I(w) - I(v+w) \tag{3.16}$$

*i.e.*

$$2I(v_1) - 2I\!I(v,w) + I(w) + I(v+w) \leq 0, \tag{3.17}$$

which implies

$$2I(\frac{v}{2}) - 2I\!I(v,w) + I(w) + I(v+w) \leq 0, \tag{3.18}$$

which is a direct contradiction of Inequality 3.13. Therefore we must have $v_1 > v/2$ and therefore the *smallest* component of $V$ must have volume *greater* than half of the volume of $V$. Any other component would have to have still greater volume, which is impossible, so $V$ must be connected.

QEF

Essentially the same proof works to show

**Corollary 3.3 ('Component Bound').** If

$$F_k(v,w) = kI\left(\frac{v}{k}\right) + I(w) + I(v+w) - 2\Pi(v,w) > 0,$$

$V$ has less than $k$ components.

## 3.2 Instability arguments

Hutchings' result on the rotational symmetry of area minimizing double bubbles (Theorem 3.1 in the previous section) underlies a series of arguments that showed that area minimizing double bubbles are standard in $\mathbf{R}^3$, $\mathbf{R}^4$, and for a range of volumes, in higher dimensions, as well as for equal volumes in $\mathbf{S}^3$ and $\mathbf{H}^3$. The symmetry, plus the component bound that follows from symmetry by way of Concavity (Theorem 3.2), give key simplifications to the geometry of the problem. However, these results do not in and of themselves finish the task.

Hutchings, Morgan, Ritoré, and Ros [23] developed an instability argument that rules out all the non-standard double bubbles left after these simplifications. (One of the most important steps was to precisely describe which non-standard double bubbles were still possible.) Reichardt *et al.* [41] adapted the instability argument to $\mathbf{R}^4$, and Cotton and Freeman [10] generalized the Hutchings-Morgan-Ritoré-Ros-Reichardt instability argument to $\mathbf{S}^3$ and $\mathbf{H}^3$, to use in their proof for the equal volumes cases of the double bubble problem in these spaces. Not a lot has to change, but there are lots of details to check; we review the statements of the main theorems from Cotton and Freeman's REU report.

### 3.2.1 Structure and Stability

**Lemma 3.10 ('Fundamental Instability Argument').** Let $\Sigma$ be a stable double bubble in $\mathbf{R}^n$, $\mathbf{S}^n$, or $\mathbf{H}^n$. Let $\mathcal{V}$ be a vectorfield corresponding to some isometric motion of $\mathbf{R}^n$, $\mathbf{S}^n$, or $\mathbf{H}^n$. Suppose that

the points where $\mathcal{V}$ is tangent to $\Sigma$ separate the bubble into at least four pieces. Then the normal component of $\mathcal{V}$ vanishes on any smooth component of $\Sigma$.

**Lemma 3.11.** Consider a stable double bubble of revolution $\Sigma \subset \mathbf{S}^n, n \geq 3$ with a piecewise smooth generating curve $\Gamma = \cup\bar{\Gamma}_i$ such that $\Gamma_i$ end either on the axis or meet in threes at vertices $v_{ijk}$. Let the axis of symmetry be denoted by $\ell$. At each $p \in \cup\Gamma_i$ let $N(p)$ denote the geodesic normal to $\Gamma$ at $p$. Consider the map

$$f : \cup\Gamma_i \ni p \mapsto N(p) \cap \ell \subset \ell \tag{3.19}$$

(that is, $f$ takes $p$ to the pair of antipodal points on $\ell$ that are determined by intersecting $\ell$ with the geodesic normal to $\Gamma$ at $p$). Let $\{p_i\}_{i=1,\ldots,k}$ be the smallest set of points in $\cup\Gamma_i$ that separates $\Gamma$ with the additional property that $f$ maps all of the '$p_i$'s to the same pair of antipodal points, which we call $(x, x')$. Then every connected component of $\Sigma$ which contains one of the points $p_i$ is part of a sphere centered at $x$ (and $x'$).

**Definition 3.4.** Two geodesics in $\mathbf{H}^n$ are *parallel* if they do not intersect but for any positive $\epsilon$ there is a point on each line such that the distance between the two points is less than $\epsilon$.

**Definition 3.5.** Two geodesics in $\mathbf{H}^n$ are *disjoint* if they do not intersect and are not parallel.

**Lemma 3.12.** Consider a stable double bubble of revolution $\Sigma \subset \mathbf{H}^n, n \geq 3$ with generating curve $\Gamma$ and axis of symmetry $\ell$ as in the previous lemma. We let $\bar{\ell}$ denote $\ell \cup \{-\infty, \infty\}$. At each $p \in \cup\Gamma_i$ we again let $N(p)$ denote the geodesic normal to $\Gamma$ at $p$, and we consider the map

$$f : \cup\Gamma_i \to \{0, 1\} \times \bar{\ell},$$

defined so that

- if $N(p)$ intersects $\ell$ then $f$ maps $p$ to $(0, N(p) \cap \ell)$,
- if $N(p)$ is parallel $\ell$ then $f$ maps $p$ to $\pm\infty$, depending on which end of $\ell$ comes arbitrarily close to $N(p)$,

- if $N(p)$ and $\ell$ are disjoint, there is a unique line $\ell'$ which intersects both $\ell$ and $N(p)$ orthogonally, and $f$ maps $p$ to $(1, \ell' \cap \ell)$.

Let $\{p_i\}_{i=1,\ldots,k}$ be the smallest set of points in $\cup\Gamma_i$ that separates $\Gamma$ with the additional property that $f$ maps all of the '$p_i$'s to the same point, which we call $x$. Then every connected component of $\Sigma$ which contains one of the points $p_i$ is part of

- a sphere centered at the second coordinate of $x$ when $x$ is of the form $(0, q)$ with $q \in \ell$,
- part of a horosphere centered at one end of $\ell$ if $x = \pm\infty$
- part of a hyposphere intersecting $\ell$ orthogonally if $x$ is of the form $(1, q)$ with $q \in \ell$.

In the hypospherical case, the hyposphere in question is generated by revolving a hypocircle that is a constant distance from the perpendicular to $\ell$ through $q$ about $\ell$.

### 3.2.2 Criteria for standardness

Given enough connectedness, the characterization of stable bubbles appearing above provides the geometrical engine that proves the double bubble theorem in constant curvature space forms. The idea is that the propositions above limit the possibilities for a non-standard double bubble with enough connectivity to be among some set of double bubbles that we can apply some volume and perimeter preserving variation to that brings about a violation of regularity. (It is the role of the Fundamental Instability Argument to carrying out this final critical step.)

**Corollary 3.4 (Structure Summary).** In $\mathbf{R}^n$, $\mathbf{S}^n$, or $\mathbf{H}^n$, any $\Gamma_i$ (as above) which can be disconnected by removing one point in its interior is a constant curvature arc which, if completed, would hit the axis of rotation $\ell$ orthogonally. In $\mathbf{R}^n$ it is a piece of a circle; similarly in $\mathbf{S}^n$; and in $\mathbf{H}^n$ it is a piece of a circle, horocycle, or hypercircle.

Adapting an argument from the William's honors thesis of Joel Foisy [**?**] about on double bubbles in $\mathbf{R}^3$, Cotton and Freeman showed that an area minimizing double bubble in $\mathbf{H}^n$ intersects its axis

of symmetry. With the addition of this final piece, Cotton and Freeman then had the right tools to prove:

**Criterion for standardness in $\mathbf{H}^n$.** An area minimizing double bubble in $\mathbf{H}^n$ in which both regions are connected must be the standard double bubble.

**Criterion for standardness in $\mathbf{S}^n$.** An area minimizing double bubble in $\mathbf{S}^n$ in which both regions and the exterior are connected must be the standard double bubble.

# Chapter 4

# s3h3

The culmination of the previous chapter was that

- If both enclosed regions and the exterior are connected, an area minimizing double bubble in $\mathbf{S}^n$ is standard.

- If both enclosed regions are connected, an area minimizing double bubble in $\mathbf{H}^n$ must be the standard double bubble.

The *other* culmination of the previous chapter (which took place in an earlier section) was that we have a criterion for connectivity, Proposition 3.2. That proposition said that if

$$2I(\frac{v}{2}) + I(w) + I(v+w) > 2\mathit{\Pi}(v,w) \tag{4.1}$$

then the region containing volume $v$ is connected. We can check this criterion by plotting

$$2I\left(\frac{v}{2}\right) + I(w) + I(v+w) \tag{4.2}$$

and

$$2\tilde{\mathit{\Pi}}(v,w), \tag{4.3}$$

(where $\tilde{\Pi}(v, w)$ gives the surface area of a standard double bubble containing volumes $v$ and $w$, and so an upper bound on $\Pi(v, w)$) and comparing the plots to see which function is bigger. In fact, both 4.2 and 4.3 are increasing functions in both variables (in $\mathbf{H}^3$; in $\mathbf{S}^3$, they are only increasing on a certain range). Where the functions are increasing, there won't be 'jumps' between plotted points. Hence to plot these functions is to prove the double bubble theorem in $\mathbf{S}^3$ and $\mathbf{H}^3$, modulo asymptotic analysis to show that the graphs of 4.2 and 4.3 continue to bear the correct relationship to each other outside of the range of the plot.

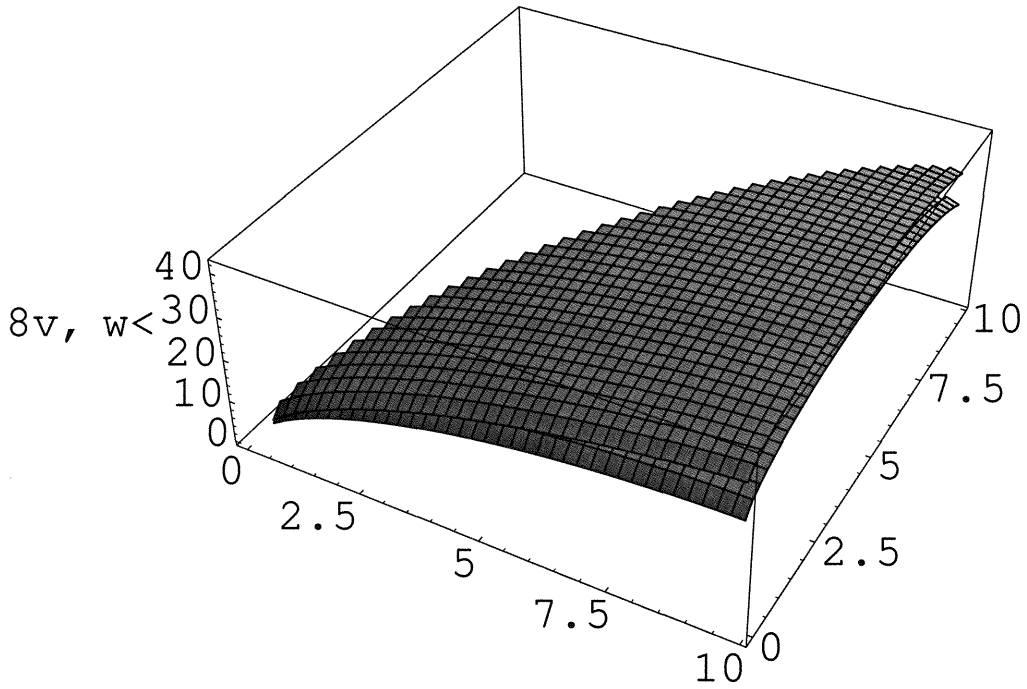

Figure 4.1: This plot proves connectivity in $\mathbf{S}^3$.

**Theorem 4.1.** The standard double bubble is the least-area way to partition $\mathbf{S}^3$ into three regions.

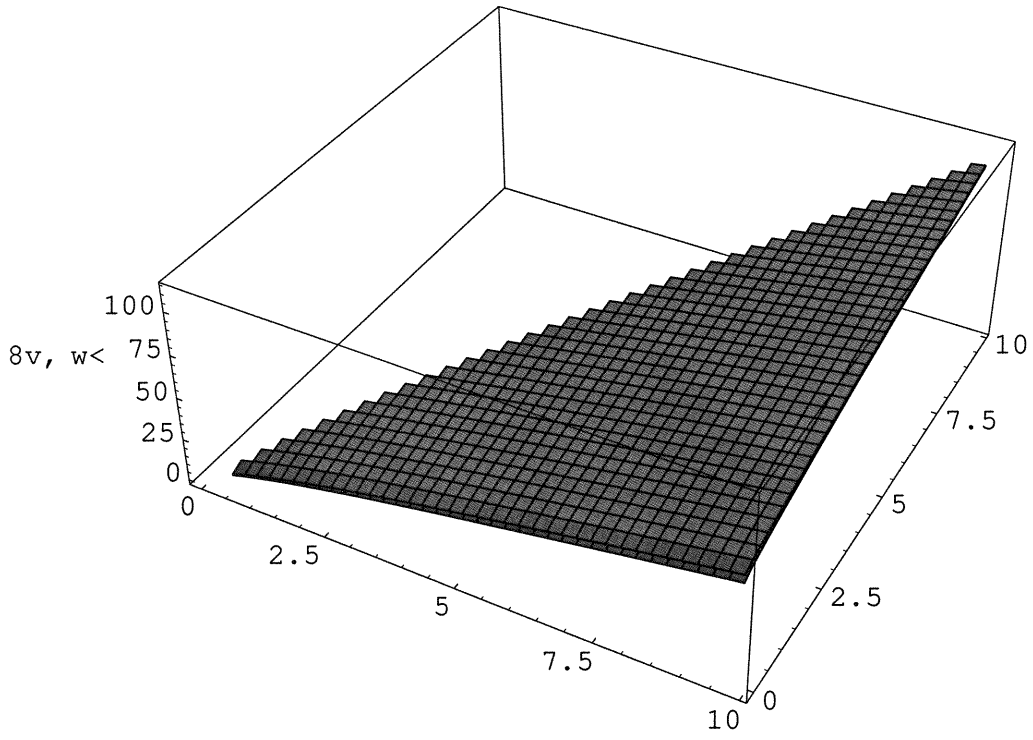

Figure 4.2: This plot is a little harder to read, but nonetheless, exhibits the bound we were looking for, proving connectivity in $\mathbf{H}^3$ for a finite range of volumes.

*"Proof".* Pending asymptotic analysis at zero, where the functions plotted are equal, the fact that the plots show that $2I(\frac{v}{2}) + I(w) + I(v+w) > 2\tilde{I}(v,w)$ on the domain where $v < |\mathbf{S}^3|/2$ and $w \leq v$ proves the claim, because the functions are increasing an this domain so the top function can not drop below the bottom function in between the mesh of the plot, and this domain is a general one in the sense that all we require is that one of the volumes takes up less than half of the total volume of the space and be larger than one of the other volumes; hence, by switching labels the properties of the given domain are representative of the properties of all volume pairs. QEF

**Theorem 4.2.** The standard double bubble is the least-area way to enclose and separate two volumes $v$ and $w$ in $\mathbf{H}^3$.

*"Proof".* The logic of this proof is the same as the proof of Theorem 4.1. Note that here, to finish the proof, not only must we study asymptotics at zero, but also through an entire quarter circle of directions heading out towards infinity. QEF

We don't have time to do the asymptotic analysis in this thesis. We satisfy ourselves with showing that the plotted formulas are correct.

## 4.1 Area and Volume Formulas

We can get a simple upper bound on $\mathit{\Pi}$ by using $\tilde{\mathit{\Pi}}$, the area of a standard double bubble, which will of course be greater than or equal to the area of the least-area double bubble. In this section we find parameterizations of the area and volumes of the standard double bubble and spheres in terms of the relevant radii (or curvatures, in the hyperbolic case). Using these parameterizations, we found $I$ and $\tilde{\mathit{\Pi}}$ numerically. In order to create Figures 4.1 and 4.2 it was necessary to take this roundabout path, because no simple closed form for the relevant functions in terms of volumes is known (or likely to be found).

The formulas is this section are derived using spherical and hyperbolic trigonometry as found without explaination in [40]; for the explaination see Thurston [55, Section 2.4].

### 4.1.1 Spheres

Here we present the standard results on volume and surface area of spheres in $\mathbf{S}^3$ and $\mathbf{H}^3$.

*Remark 4.1.* The formulas for surface area of a sphere of radius $r$ in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$A_{\mathbf{S}^3} = 4\pi \sin^2 r$$

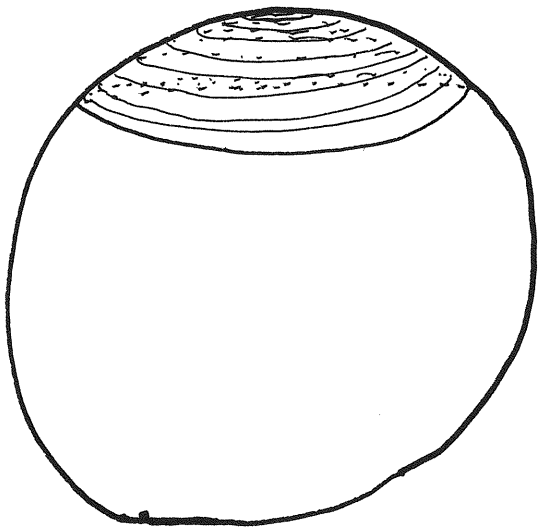

Figure 4.3: Spherical cap on sphere

$$A_{\mathbf{H}^3} = 4\pi \sinh^2 r$$

The volume formulas for a ball of radius r in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$V_{\mathbf{S}^3} = \pi(2r - \sin 2r)$$

$$V_{\mathbf{H}^3} = \pi(\sinh 2r - 2r)$$

**Lemma 4.1.** The mean curvatures, $\frac{dA}{dV}$, of spheres of radius $r$ in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$(\mathbf{S}^3) \qquad 2\cot r \tag{4.4}$$

$$(\mathbf{H}^3) \qquad 2\coth r. \tag{4.5}$$

*Proof.* This is a special case of the computation appearing in Lemma 3.8. QEF

### 4.1.2 Spherical Caps

Even though it seems out of line with the name of the chapter, in this section we will prove the results we want in the Euclidean setting and then state the $\mathbf{S}^3$ and $\mathbf{H}^3$ versions as corollaries.

**Proposition 4.1.** In Euclidian space the volume of a spherical cap belonging to a sphere of radius $r$

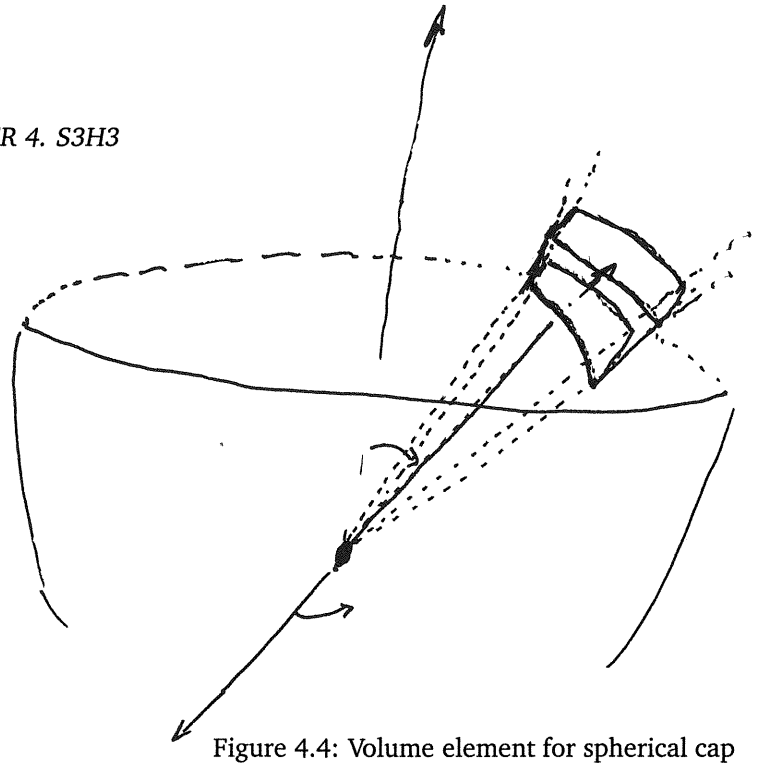

Figure 4.4: Volume element for spherical cap

and subtended by an angle of $2\varphi_0$ is given by

$$\int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \int_{\frac{r\cos\varphi_0}{\cos(\varphi)}}^{r} d\rho\, \rho^2 \sin\varphi$$

*Proof.* Spherical coordinates in $\mathbf{R}^3$

$$\begin{aligned} x &= \rho\cos\theta\sin\varphi \\ y &= \rho\sin\theta\sin\varphi \\ z &= \rho\sin\varphi \end{aligned} \tag{4.6}$$

have an associated Jacobian of $\rho^2\sin\varphi$. We do the integral in the standard way, *around* the sphere, *through* all the azimuthal angles, and *from* the disk that bounds the cap to the surface of the sphere (Figure 4.4). For this parameterization, we choose to have $\varphi$ run *down* from the north pole of the sphere, since this makes the formulas come out simpler.

A little bit of trig gives the correct bounds for the integral. Actually, given the strategy above, the only question is what the lower bound is on the '$\rho$' integral. (See Figure 4.5.)

We want to solve for $\rho_0$. The distance from the diameter $d$ to the point $p$ is $\rho_0\sin(\varphi)$. The distance from the center of the sphere to the base of the cap is $r\cos\varphi$. By the pythagorean theorem, we have

$$\rho_0^2\sin^2(\varphi) + r^2\cos^2\varphi_0 = \varphi_0^2.$$

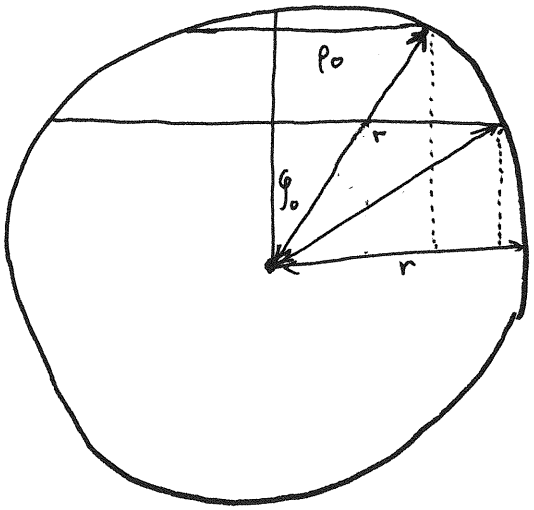

Figure 4.5: Find Lower Bound For $\rho$ Using Trig

Hence,

$$\rho_0^2(1-\sin^2(\varphi)) = r^2\cos^2\varphi_0,$$

so

$$\rho_0 = \sqrt{\frac{r^2\cos^2\varphi_0}{1-\sin^2(\varphi)}} = \frac{r\cos\varphi_0}{\cos(\varphi)}$$

QEF

**Corollary 4.1.** The corresponding formulas in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$(\mathbf{S}^3) \qquad \int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \int_{\tan^{-1}(\frac{\tan r\cos\varphi_0}{\cos(\varphi)})}^{r} d\rho\ \sin^2(\rho)\sin\varphi \tag{4.7}$$

$$(\mathbf{H}^3) \qquad \int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \int_{\tanh^{-1}(\frac{\tanh r\cos\varphi_0}{\cos(\varphi)})}^{r} d\rho\ \sinh^2(\rho)\sin\varphi. \tag{4.8}$$

*Proof.* For spherical coordinates in these spaces replace $\rho$ in the parameterization of Equations 4.6 by $\sin\rho$ or $\sinh\rho$ respectively, and use spherical or hyperbolic trigonometry in Figure 4.5. QEF

**Corollary 4.2.** (Formulas for Volume of Spherical Caps) The volume of a spherical cap of radius $r$ that is subtended by an angle $2\varphi_0$ is

$$(\mathbf{S}^3) \qquad -\pi(\tan^{-1}(\cos\varphi_0\tan r) - r\cos\varphi_0 + (-1+\cos\varphi_0)(r-\cos r\sin r)) \tag{4.9}$$

$$(\mathbf{H}^3) \qquad \pi(-r+\tanh^{-1}(\cos\varphi_0\tanh r) - \cos\varphi_0\cosh r\sinh r + \cosh r\sinh r))). \tag{4.10}$$

*Proof.* We did the integrals symbolically in *Mathematica*. QEF

**Proposition 4.2.** In Euclidian space the surface area of a spherical cap belonging to a sphere of radius $r$ and subtended by an angle of $2\varphi_0$ is given by

$$\int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \, r^2 \sin\varphi$$

*Proof.* The equation for a hemisphere of radius $r$ is $f(x,y) = \sqrt{r^2 - x^2 - y^2}$. The area integral is

$$\int_{\text{projection}} \sqrt{1 + \left(\frac{df}{dx}\right)^2 + \left(\frac{df}{dx}\right)^2}\, dxdy.$$

Calculating the derivatives and subsitituting in polar coordinates

$$\begin{aligned} x &= \rho\cos\theta \\ y &= \rho\sin\theta, \end{aligned} \tag{4.11}$$

this becomes

$$\int_0^{2\pi} d\theta \int_0^{\rho_0} d\rho \, \rho \sqrt{1 + \frac{\rho^2}{r^2 - \rho^2}},$$

From Figure 4.5, $\rho_0$ is seen to be $r\sin\varphi_0$. The following sequence of transformations then gives the stated form:

$$\begin{aligned} \int_0^{2\pi} d\theta \int_0^{r\sin\varphi_0} d\rho \, \rho \sqrt{1 + \frac{\rho^2}{r^2 - \rho^2}} &= \int_0^{2\pi} d\theta \int_0^{r\sin\varphi_0} d\rho \, \rho \sqrt{\frac{r^2}{r^2 - \rho^2}} \\ &= \int_0^{2\pi} d\theta \int_0^{r\sin\varphi_0} d\rho \, \rho \frac{1}{\sqrt{1 - (\frac{\rho}{r})^2}} \end{aligned} \tag{4.12}$$

(putting $\bar\rho = \rho/r$, we note that $d\bar\rho = \frac{1}{r}d\rho$, and that $\rho = r\sin\varphi_0$ implies $\bar\rho = \sin\varphi_0$, so 4.12 can be written:)

$$= \int_0^{2\pi} d\theta \int_0^{\sin\varphi_0} d\bar\rho \, r^2 \bar\rho \frac{1}{1 - \bar\rho^2} \tag{4.13}$$

(4.14)

(in general, $\bar\rho = \sin\varphi$, so $d\varphi = d(\sin^{-1}\bar\rho) = \frac{1}{\sqrt{1-\bar\rho^2}}d\bar\rho$, and we note that if $\rho = \rho_0 = r\sin\varphi_0$, then $\varphi = \varphi_0$, so we end with this change of variables:)

$$= \int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \, r^2 \sin\varphi. \tag{4.15}$$

QEF

**Corollary 4.3.** The corresponding formulas in $\mathbf{S}^3$ and $\mathbf{H}^3$ are

$$(\mathbf{S}^3) \qquad \int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \ \sin^2 r \sin\varphi \tag{4.16}$$

$$(\mathbf{H}^3) \qquad \int_0^{2\pi} d\theta \int_0^{\varphi_0} d\varphi \ \sinh^2 r \sin\varphi \tag{4.17}$$

*Proof.* For spherical coordinates in these spaces replace $\rho$ in the parameterization of Equations 4.11 by $\sin\rho$ or $\sinh\rho$ respectively, and use spherical or hyperbolic trigonometry in Figure 2. QEF

**Corollary 4.4.** (Formulas for Area of Spherical Caps) The area of a spherical cap of radius $r$ subtended by an angle $2\varphi_0$ is

$$(\mathbf{S}^3) \qquad 2\pi \sin^2 r(1-\cos\varphi_0) \tag{4.18}$$

$$(\mathbf{H}^3) \qquad 2\pi \sinh^2 r(1-\cos\varphi_0). \tag{4.19}$$

*Proof.* These integrals can be done in ones head. QEF

### 4.1.3 Standard Double Bubbles

Since each standard double bubble in $\mathbf{S}^3$ and $\mathbf{H}^3$ is symmetric about a geodesic line, it is convenient to compute area and volume of a standard double bubble by considering the revolution of some generating curve consisting of 3 circular arcs meeting at 120°. Figure 4.6 represents an arbitrary generating curve (and its reflection about the line of symmetry) labelled with relevant measurements.

**Spherical Space** From Figure 4.6 and repeated application of an identity of spherical trigonometry (see Figure 4.7) we have

$$\sin\varphi_1 \quad = \quad \frac{\sin x}{\sin r_1};$$

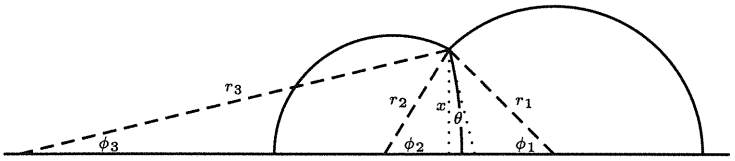

Figure 4.6: Some important geometrical features of the generating curve for a standard double bubble.

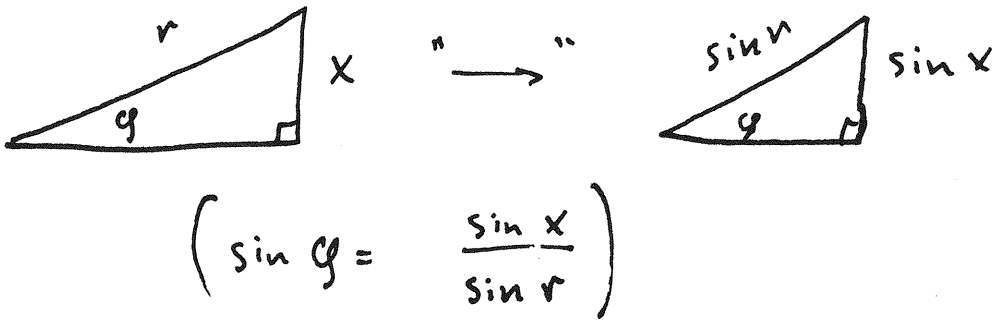

Figure 4.7: Sphere sine relation

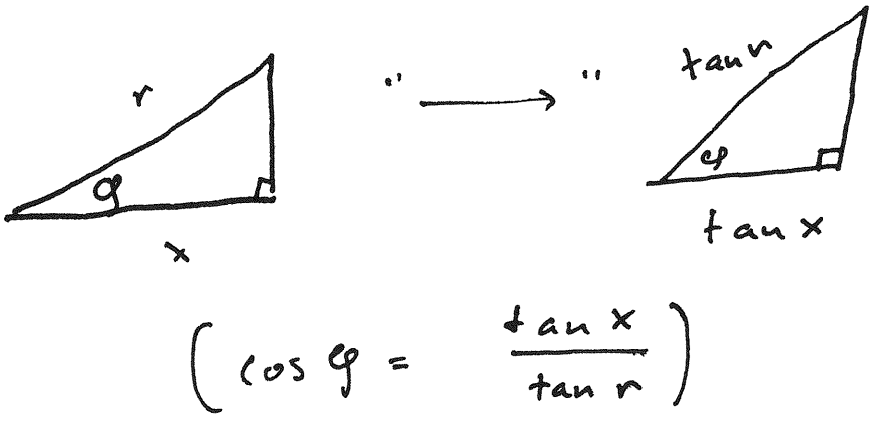

Figure 4.8: Sphere tantancos

$$\begin{aligned} \sin\varphi_2 &= \frac{\sin x}{\sin r_2}; \\ \sin\varphi_3 &= \frac{\sin x}{\sin r_3}. \end{aligned}$$

Another identity (see Figure 4.8) yields

$$\begin{aligned} \tan x &= \tan r_1 \cos(\frac{\pi}{6} - \theta); \\ \tan x &= \tan r_2 \cos(\frac{\pi}{6} + \theta); \end{aligned}$$

or

$$\begin{aligned} \tan x &= \tan r_1 (\frac{\sqrt{3}}{2}\cos\theta + \frac{1}{2}\sin\theta); \\ \tan x &= \tan r_2 (\frac{\sqrt{3}}{2}\cos\theta - \frac{1}{2}\sin\theta). \end{aligned}$$

Solving for $\theta$, we get

$$\theta = \tan^{-1}(\frac{\sqrt{3}(\tan r_2 - \tan r_1)}{\tan r_1 + \tan r_2}).$$

We can plug this into the first of the two preceding equations above and rearrange terms to get

$$x = \tan^{-1}(\tan r_1 \cos(\frac{\pi}{6} - \tan^{-1}(\frac{\sqrt{3}(\tan r_2 - \tan r_1)}{\tan r_1 + \tan r_2}))),$$

which we can put into the first triple of equations to obtain a (complicated) expression for the '$\varphi$'s in terms of $r_1$ and $r_2$:

$$\varphi_1 = \sin^{-1}\left(\frac{\sin(\tan^{-1}(\tan r_1 \cos(\frac{\pi}{6} - \tan^{-1}(\frac{\sqrt{3}(\tan r_2 - \tan r_1)}{\tan r_1 + \tan r_2}))))}{\sin r_1}\right);$$

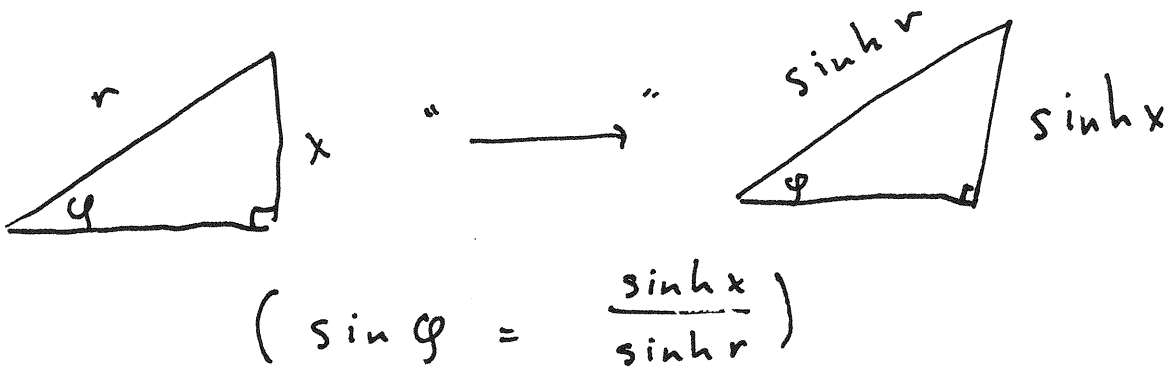

Figure 4.9: Hyperbolic sine relation

$$\varphi_2 = \sin^{-1}\left(\frac{\sin(\tan^{-1}(\tan r_1 \cos(\frac{\pi}{6} - \tan^{-1}(\frac{\sqrt{3}(\tan r_2 - \tan r_1)}{\tan r_1 + \tan r_2}))))}{\sin r_2}\right);$$

$$\varphi_3 = \sin^{-1}\left(\frac{\sin(\tan^{-1}(\tan r_1 \cos(\frac{\pi}{6} - \tan^{-1}(\frac{\sqrt{3}(\tan r_2 - \tan r_1)}{\tan r_1 + \tan r_2}))))}{\sin r_3}\right).$$

Note that there are only two relevant parameters here. Since pressures add, we have $r_3$ in terms of $r_1$ and $r_2$:

$$2\cot r_3 = 2\cot r_1 - 2\cot r_2,$$

or

$$r_3 = \cot^{-1}(\cot r_1 - \cot r_2).$$

**Hyperbolic Space** We derive similar formulas for the angles $\varphi_i$, but this time using trigonometric identities in hyperbolic space (see Figures 4.9 and 4.10):

$$\begin{aligned}
\sin\varphi_i &= \frac{\sinh x}{\sinh r_i}\ (i = 1, 2, 3); \\
\tanh x &= \tanh r_1 \cos(\frac{\pi}{6} - \theta); \\
\tanh x &= \tanh r_2 \cos(\frac{\pi}{6} + \theta).
\end{aligned}$$

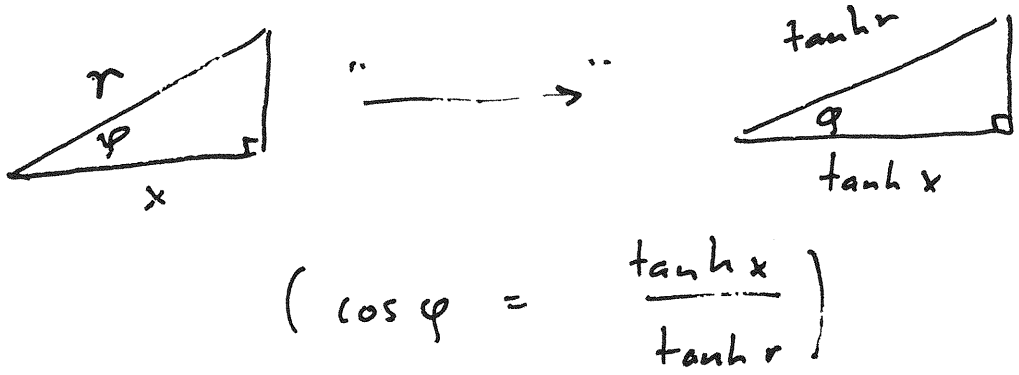

Figure 4.10: Hyperbolic tantancos

Solving for $\varphi_i$ (i = 1, 2, 3) yields

$$\varphi_i = \sin^{-1}\left(\frac{\sinh(\tanh^{-1}(\tanh r_1 \cos(\frac{\pi}{6} - \tan^{-1}(\frac{\sqrt{3}(\tanh r_2 - \tanh r_1)}{\tanh r_1 + \tanh r_2}))))}{\sinh r_i}\right)$$

So far this derivation has been analogous to the work we did in $\mathbf{S}^3$. But in hyperbolic space we have already mentioned the fact that not all hypersphere-like submanifolds in hyperbolic space have well-defined radii. We work around this by computing area and volume of double bubbles in $\mathbf{H}^3$ in terms of curvature. To do this, we derive the area and volume formulas as before, and convert formulas using the relation:

$$k = \coth r \tag{4.20}$$

The wonderful fact is that analytic continuation implies that our new formulas yield the desired areas and volumes.

We can now compute $\varphi_i$ in terms of $k_1$ and $k_2$ (the curvatures of the two outer caps). Here, the curvature constraint gives, $k_3 = k_1 - k_2$.

$$\varphi_1 = \sin^{-1}\left(\frac{\sqrt{1-\frac{1}{k_1^2}}\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{\sqrt{1-\frac{\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{k_1^2}}}\right)$$

$$\varphi_2 = \sin^{-1}\left(\frac{k_2\sqrt{1-\frac{1}{k_2^2}}\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{k_1\sqrt{1-\frac{\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{k_1^2}}}\right)$$

$$\varphi_3 = \sin^{-1}\left(\frac{(k_1-k_2)\sqrt{1-\frac{1}{(k_1-k_2)^2}}\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{k_1\sqrt{1-\frac{\cos(\frac{\pi}{6}-\tan^{-1}(\frac{\sqrt{3}(k_1-k_2)}{k_1+k_2}))}{k_1^2}}}\right)$$

*Remark 4.2.* Now we can compute the volumes and surface area of standard double bubbles, in terms of the radii or curvatures of the outer caps, by substituting the formulas we have just derived in Corollary 4.2 and Corollary 4.4. Refering to Figure 4.6, we observe that the angle $\varphi_1$ is either acute or obtuse depending on the relative size of the two bubbles; the transition between regimes is when $\varphi_1$ is 90°. Tracing back through the equations, we notice that this happens when

$$\frac{\tan(r_2)-\tan(r_1)}{\tan(r_2)+\tan(r_1)} = 1/3 \quad (\text{in } \mathbf{S}^3)$$

and when

$$\frac{k_1-k_2}{k_1+k_2} = 1/3 \quad (\text{in } \mathbf{H}^3)$$

We must make adjustments to $\varphi_1$ in our computations accordingly. Specifically, if $\varphi_1 < \frac{\pi}{2}$, the formulas return values corresponding to a cap that is larger than a hemisphere, which is what we desired, otherwise they return values corresponding to a cap smaller than a hemisphere, so we have to use $\pi - \varphi_1$ in place of $\varphi_1$.

**Definition 4.1.** In light of the last remark, we define $\widehat{\varphi}_1$ to be equal to $\varphi_1$ if $\varphi_1 < \frac{\pi}{2}$ and to be $\pi - \varphi_1$ otherwise.

Now, the following lemma summarizes how we compute area and volumes for the standard double bubble.

**Lemma 4.2.** The volume of the first bubble is the volume of the spherical cap in the sphere of radius $r_1$ subtended by an angle $2\widehat{\varphi}_1$, plus the volume of the spherical cap in the sphere of radius $r_3$ subtended by an angle $2\varphi_3$. The volume of the second bubble is the volume of the spherical cap in the sphere of radius $r_2$ subtended by an angle $2(\pi - \varphi_2)$, minus the volume of the spherical cap in the sphere of radius $r_3$ subtended by angle $2\varphi_3$.

*Proof.* For each bubble component, we compute the volume and area of the spherical cap which separates it from the exterior. For area of the double bubble, we simply add these areas plus the area of the separating cap. To compute the volume of each bubble component we have to include the volume contained within the separating cap in the smaller region, and exclude it from the larger region. QEF

## 4.2 The Curvature Conjecture

The inequality we have been studying in this chapter is

$$\hat{F}(v,w) = 2I(\frac{v}{2}) + I(w) + I(v+w) - 2\tilde{\Pi}(v,w) > 0 \tag{4.21}$$

$\tilde{\Pi}(v,w)$ denotes the surface area of the standard double bubble enclosing the volumes $v$ and $w$.

We can perturb the definition of $F_k$ of Corollary 6.2 in the same way to deduce that if

$$\hat{F}_k(v,w) = kI(\frac{v}{k}) + I(w) + I(v+w) - 2\tilde{\Pi}(v,w) > 0 \tag{4.22}$$

then $V$ has less than $k$ components.

Lemma 3.8 tells us that $kI(\frac{v}{k})$ is increasing in $k$. Therefore there is some largest $k$ for which the Basic Estimate Lemma 3.9 (with $x = \frac{v}{k}$) applies *i.e.* for this $k$ we have $2\Pi(v,w) = I(w) + \tilde{k}I(\frac{v}{\tilde{k}}) + I(v+w)$. A possibly even greater '$k$', which we will call $\tilde{k}$ satisfies

$$2\tilde{\Pi}(v,w) = I(w) + \tilde{k}I(\frac{v}{\tilde{k}}) + I(v+w). \tag{4.23}$$

This defines $\tilde{k}$ implicitly as a function of $v$ and $w$.

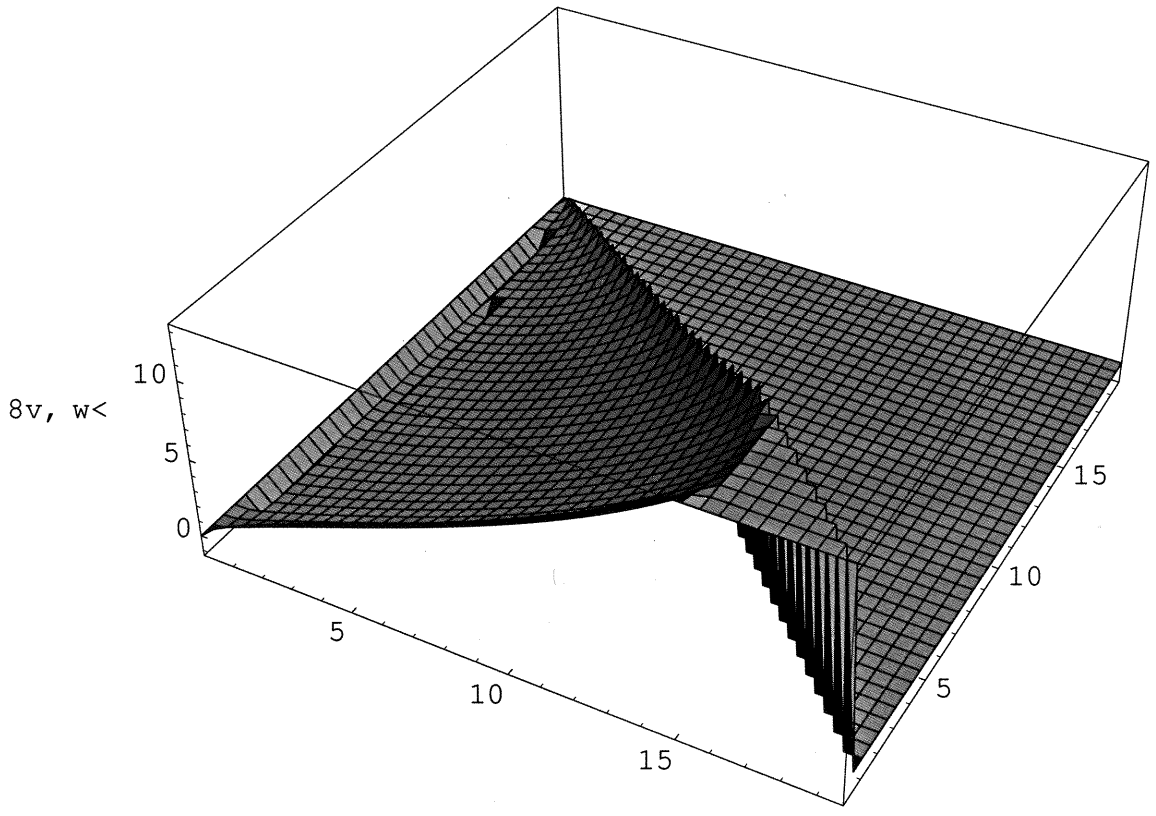
In light of the fact that mean curvature is proportional to the derivative of area with respect to volume, differentiating Equation 4.23 gives

$$\frac{d(\tilde{k}I(\frac{v}{k}))}{dw} = kH_{v/k} - H_w - H_{w+v} \tag{4.24}$$

$$\frac{d(\tilde{k}I(\frac{v}{k}))}{dv} = kH_{v/k} - H_{w+v}. \tag{4.25}$$

(*N. B.* Upon differentiating the surface area of the standard double bubble with respect to one of the volumes, we only pick up the curvature of the outer cap because (a) the standard double bubble is stable under small variations; and (b) therefore all variations must give the same $dA/dv$ or some combination could reduce perimeter, contradicting (a); (c) a variation that raises a small bump on the outer cap picks up its curvature.)

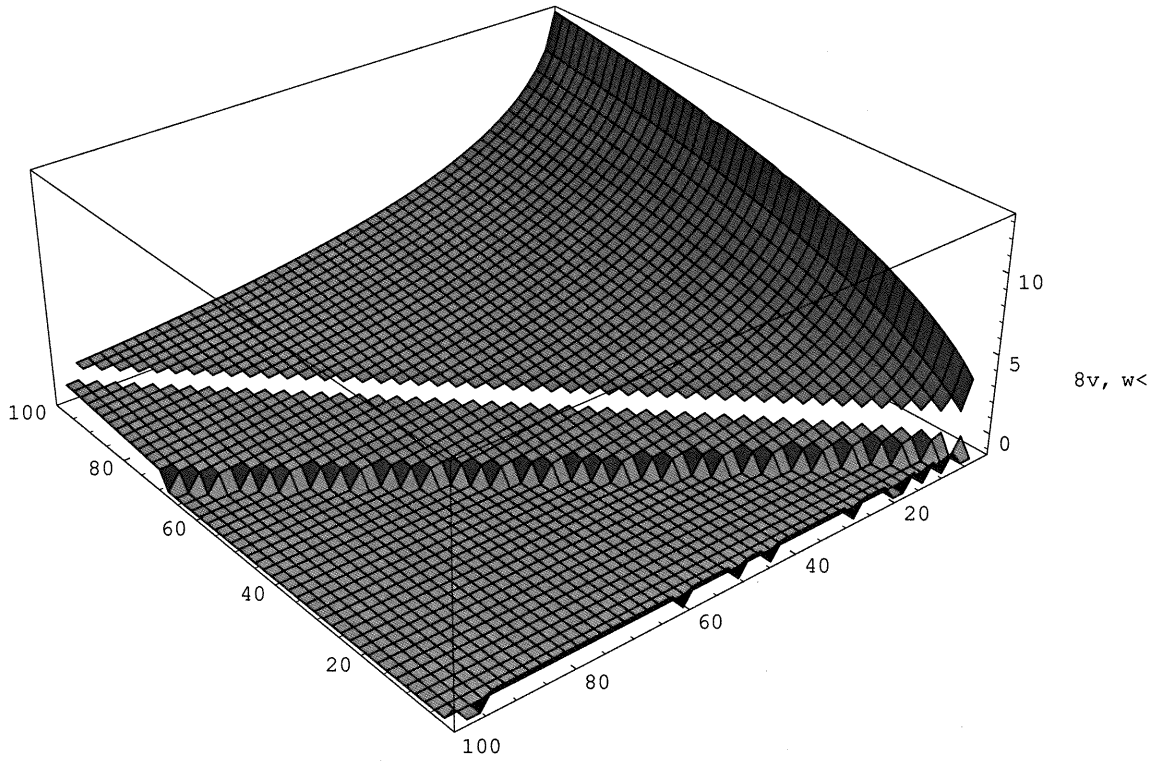
The curvature conjecture says that each of 4.24 and 4.25 is signed. Specifically, in the most important case $k < 2$, we have:



**Conjecture 4.1.** Curvature Conjecture In $\mathbf{R}^n$, $\mathbf{S}^n$, or $\mathbf{H}^n$, the various mean curvatures associated with standard double bubbles satisfy the following inequalities, where we $H_x$ denote the curvature of a sphere of volume $x$ and we let $H_{x,y}$ denote the curvature of the the outer cap of the '$x$ component' of a standard double bubble containing volumes $x$ and $y$

$$H_{v,w} > \frac{H_{v/2} + H_{w+v}}{2}.$$

$$H_{w,v} < \frac{H_{v/2} + H_{w+v}}{2}.$$



If this conjecture is true, then $\hat{F}$ is a decreasing function one of the variables and an increasing function in the other, and so plots of $\hat{F}$ will not have jumps in between the mesh of the plot. Plots and analysis suggest that the curvature conjecture holds in $\mathbf{R}^n$, although the analysis part is not complete. In $\mathbf{R}^n$, the volumes can be normalized so that one of the volumes is equal to one. David Futer then showed that in the case that the other volume is bigger than one. The proof uses the fact that the standard double bubble is invariant under inversion in the sphere that separating cap is a piece of.

Since we already know that the component functions of $\hat{F}$ are increasing, we are probably better off studying them. At present, plots of the function $\hat{F}$ are useful because they show (non-rigorously) what the gaps between the functions plotted in Figures 4.1 and 4.2 look like.

*The function value is lowered artificially on region where graph is negative for ease of viewing.*

Figure 4.11: The Hutchings function $\hat{F}(v, w)$ in $\mathbf{S}^3$.

*The function value is lowered artificially on regions where graph is negative for ease of viewing; the gap on the diagonal is due to a singularity in our formulas that doesn't show up in the proof-plots for some reason. Cotton and Freeman already treated the diagonal in detail anyway.*

**Charter.** We prove that the least-area division of $n$-dimensional Gauss space into three equal pieces is given by the standard configuration of three $(n-1)$-dimensional hyperplanes meeting along an $(n-2)$-dimensional hyperplane at 120°.

## 5.1 Introduction

Let $\mathbf{G}^n$ denote $\mathbf{R}^n$ with the volume form weighted by Gaussian measure and area given by restricting this measure to $(n-1)$-dimensional subsets in the standard fashion (the area of an $(n-1)$-dimensional subset $A$ is given by finding the derivative with respect to $\epsilon$ at zero of the volume of $\epsilon$-tubes about $A$, so, for example, a hyperplane through the origin has total $(n-1)$-dimensional measure of $1/2\pi$). Borell [4], Sudakov-Tsirel'son [51] and others (cf. Barthe and Maurey [2] and the references therein) showed that the solution to the isoperimetric problem in this space (that is, the least-area division of $\mathbf{G}^n$ into two regions of prescribed volume) is given by an $(n-1)$-dimensional hyperplane. Our Theorem 5.1 will show that the least-area division of Gauss space into three pieces of equal size is given by a 'Y', that is, by three half-hyperplanes meeting each other at 120°along an

$(n-2)$-dimensional plane through the origin.

Theorem 5.1 solves a 'double bubble problem', the name given to the problem of enclosing and separating two regions of prescibed volume in a give space with the least area. This problem has recently been solved in $\mathbf{R}^3$ by Hutchings, Morgan, Ritoré and Ros ([23], see [34]).

**The proof.** A classical observation ascribed to Poincaré (Proposition 5.1) says that $\mathbf{G}^n$ can be realized as a limit of projections from $\mathbf{S}^N$ onto $\mathbf{R}^n$ as $N$ goes to infinity and the radius of $\mathbf{S}^N$ grows. This reduces the problem to studying double bubbles in $\mathbf{S}^N$.

Hutchings' theory of the structure of area minimizing double bubbles in spheres [22] shows how to bound the number of components of minimizing bubbles that divide the $\mathbf{S}^N$ into three equal volumes. Using this connectivity result, an argument based on the that used in $\mathbf{R}^3$ [23, Section 6] shows that minimizing double bubbles must be standard. Taking limits of projections onto $\mathbf{S}^n$ then gives the result.

**Acknowledgements** Theorem 5.1 came out of conversations with Frank Morgan about a lecture by Antonio Ros (and the lecture notes [44]). Morgan provided lots of useful ideas about how to *prove* the theorem. Pat McDonald had a number of very helpful conversations with me on this topic.

## 5.2 The Geometry of Gauss Space

Proposition 5.1, attributed to Poincaré shows that $n$-dimensional Gauss space is the limit of projections onto $\mathbf{R}^n$ of uniform measure on spheres whose size and dimension grow in a prescibed way. The proof of Proposition 5.1 is based on that found in McKean [30]. We also point out that it is very easy to compute areas of hyperplanes and pieces of hyperplanes in $\mathbf{G}^n$ (Proposition 5.2), reducing this to computations with a one-dimensional Gaussian.

**Proposition 5.1 (attrib. Poincaré).** Gauss space of $n$ dimensions is realized as the limit as $N \to \infty$ of projections of $\mathbf{S}^N(\sqrt{N})$ onto some fixed $\mathbf{R}^n$.

*Proof.* Because of how we have defined volumes and areas in $\mathbf{G}^n$, it suffices to show that if $\mathbf{x} = (x_1, ...x_N)$ is uniformly distributed on $S^N(\sqrt{N})$, then for fixed $n < \infty$ the probability that $\mathbf{x}$ is in the box $(\mathbf{a}, \mathbf{b}) = (a_1, b_1) \times \ldots \times (a_n, b_n) \subset \mathbf{R}^n$ is equal to the integral of $n$-dimensional Gaussian measure over this box. In symbols, what we wish to prove is:

$$\lim_{N\to\infty} P(\cap_{i=1}^n (a_i \leq x_i \leq b_i)) = \prod_{i=1}^n \int_{a_i}^{b_i} \frac{e^{-x_i^2/2}}{\sqrt{2\pi}} dx_i.$$

The probablity that $\mathbf{x}$ is in $(\mathbf{a}, \mathbf{b})$ is given by the integral of the area form $dA$ induced by the volume form on $\mathbf{R}^{N+1}$ over pieces of the sphere that lie 'above' or 'below' $(\mathbf{a}, \mathbf{b})$, divided by the total measure of $\mathbf{S}^N$, *i.e.* the integral of $dA$ over $\mathbf{S}^N$.

The form of the integral is given in three dimensions by parameterizing by the azimuthal angle $\varphi$, so if $R = \sqrt{N}$, then $x_3 = R\cos\varphi$, and $dx_3 = R\sin\varphi\, d\varphi$, which by trigonometry is $\sqrt{R^2 - x_3^2}$. We also have $dA = 2\pi R \sin\varphi\, d\varphi = 2\pi\sqrt{R^2 - x_3^2}\, d\varphi$, which is therefore just $2\pi\, dx_3$. We rotate so that $x = x_3$, so the area form is proportional to $(1 - \frac{x^2}{N})^0$.

By an analogous procedure in higher dimensions the probability that $\mathbf{x}$ lies above or below an interval $(a, b)$ (that is, the probability that one of the dimesions $x$ of $\mathbf{x}$ is in the range of values for which $\mathbf{x}$ might be in the box $(\mathbf{a}, \mathbf{b})$ that we specified, not taking into account what is going on in the other dimensions) works out to be

$$\frac{\int_a^b (\sqrt{N}^2 - x^2)^{(N-3)/2}\, dx}{\int_{-\sqrt{N}}^{\sqrt{N}} (\sqrt{N}^2 - x^2)^{(N-3)/2}\, dx} = \frac{\int_a^b (1 - x^2/N)^{(N-3)/2}\, dx}{\int_{-\sqrt{N}}^{\sqrt{N}} (1 - x^2/N)^{(N-3)/2}\, dx}. \tag{5.1}$$

Recall that $e^x = \lim_{n\to\infty}(1 + \frac{x}{n})^n$, so $e^{-x^2} = \lim_{n\to\infty}(1 - \frac{x^2/2}{n})^n = \lim_{n\to\infty}(1 - \frac{x^2}{n})^{n/2}$. It is easy to check that this is $\lim_{n\to\infty}(1 - \frac{x^2}{n})^{(n-3)/2}$. Therefore as $n \to \infty$, the ratio in Equation 5.1 approximates $\int_a^b \frac{e^{-x^2/2}}{\sqrt{2\pi}} dx$. The linearity of the integral now gives the stated form for the integral over a box. QEF

**Proposition 5.2.** The $(n-1)$-dimensional measure of a hyperplane that divides $\mathbf{G}^n$ into two pieces of any given ratio is the same for all $n$.

*Proof.* To prove this, we need to use the basic fact that an $(n-1)$-hyperplane has an $(n-1)$-dimensional Gaussian on it, whose total measure depends only on its distance from the origin and not on the dimension. This is a consequence of the fact that up to normalization, $\mathbf{G}^n = \mathbf{G}^{n-1} \times \mathbf{G}^1$. For any given volume ratio and any $n > 1$, a hyperplane $P$ whose distance from the origin is the same as the distance from the origin of a point $p$ in $\mathbf{G}^1$ that cuts $\mathbf{G}^1$ into pieces with the given ratio will cut each perpendicular hyperplane $H$ into two pieces of the given ratio, and so it cuts $\mathbf{G}^n$ into two pieces of the given ratio. Since the total measure of this $P$ depends only on its distance from the origin, this proves the claim. QEF

**Corollary 5.1.** The $(n-1)$-dimensional measure of three half-hyperplanes that divides $\mathbf{G}^n$ into three pieces of equal volume is the same for all $n > 2$.

*Proof.* Three half-hyperplanes through the origin have total $(n-1)$-dimensional measure $\frac{1}{\sqrt{2\pi}}\frac{3}{2}$. QEF

## 5.3 Area-minimizing division of $\mathbf{G}^n$

We now introduce some notation. We let $I_{\mathbf{G}^n}$ denote the isoperimetric profile of $\mathbf{G}^n$. By Proposition 5.2, the surface area of a standard single bubble is given by the same function in $\mathbf{G}^n$ and $\mathbf{G}^1$, and can be written down (fairly) explicitly: $I_{\mathbf{G}^n}(v) = I_{\mathbf{G}^1}(v) = \frac{1}{\sqrt{2\pi}}e^{-x^2/2}$, where $x$ is defined by $\int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}}e^{-t^2/2}\,dt = v$. We let $I\!I_{\mathbf{G}^n}$ denote the two-volume least-area function of $\mathbf{G}^n$.

We will denote the isoperimetric profile and two-volume least-area function of $\mathbf{S}^m$ by $I_{\mathbf{S}^m}$ and $I\!I_{\mathbf{S}^m}$ respectively. These can be thought of classically or by using a Hausdorff measure construction. Viewed the latter way, we can the realize the functions $I_{\mathbf{G}^n}$ and $I\!I_{\mathbf{G}^n}$ as projections of limits of $I_{\mathbf{S}^m}$ and $I_{\mathbf{S}^m}$.

Hutchings theory [22] says that if

$$F(v,w) = 2I_{\mathbf{S}^m}(v/2) + I_{\mathbf{S}^m}(w) + I_{\mathbf{S}^m}(v+w) - 2\Pi_{\mathbf{S}^m}(v,w) > 0 \tag{5.2}$$

then the region containing the volume $v$ in an area-minimizing double bubble in $\mathbf{S}^m$ that contains volumes $v$ and $w$ is connected. As discussed in the previous two chapters

$$\tilde{F}(v,w) = 2I_{\mathbf{S}^m}(v/2) + I_{\mathbf{S}^m}(w) + I_{\mathbf{S}^m}(v+w) - 2\widetilde{\Pi}_{\mathbf{S}^m}(v,w) > 0, \tag{5.3}$$

where $\widetilde{\Pi}_{\mathbf{S}^m}(v,w)$ denotes the area of a standard double bubble containing volumes $v$ and $w$, is also a condition for connectivity.

Taken together we now have enough tools to prove our theorem.

**Theorem 5.1.** For $n > 1$, the least-area division of $n$-dimensional Gauss Space $\mathbf{G}^n$ into three equal pieces consists of three hyperplanes, meeting at one hundred and twenty degrees along an $(n-2)$-dimensional plane through the origin.

*Proof.* In the case of three equal volumes in $\mathbf{S}^m(\sqrt{m})$, with $v = |\mathbf{S}^m(\sqrt{m})|$, the Hutchings criterion 5.3 becomes

$$2I_{\mathbf{S}^m}\left(\frac{v}{6}\right) + I_{\mathbf{S}^m}\left(\frac{v}{3}\right) + I_{\mathbf{S}^m}\left(\frac{2v}{3}\right) - 2\widetilde{\Pi}_{\mathbf{S}^m}\left(\frac{v}{3},\frac{v}{3}\right) > 0. \tag{5.4}$$

By symmetry, if this inequality holds, all of the regions in are connected.

By the considerations of Proposition 5.1, there is some $N$ such that if $m > N$ then

$$2I_{\mathbf{G}^n}\left(\frac{1}{6}\right) + I_{\mathbf{G}^n}\left(\frac{1}{3}\right) + I_{\mathbf{G}^n}\left(\frac{2}{3}\right) - 2\widetilde{\Pi}_{\mathbf{G}^n}\left(\frac{1}{3},\frac{1}{3}\right) > 0 \tag{5.5}$$

is a criterion for connectivity in $\mathbf{S}^m$.

By the considerations of Proposition 5.2, this last criterion is the same as

$$2I_{\mathbf{G}^1}\left(\frac{1}{6}\right) + I_{\mathbf{G}^1}\left(\frac{1}{3}\right) + I_{\mathbf{G}^1}\left(\frac{2}{3}\right) - 2\left(\frac{1}{\sqrt{2\pi}}\frac{3}{2}\right) > 0, \tag{5.6}$$

which proves that Inequality 5.5 establishes a lower bound that is uniform in $n$. By symmetry, Inequality 5.6 is equivalent to

$$2I_{\mathbf{G}^1}\left(\frac{1}{6}\right) + 2I_{\mathbf{G}^1}\left(\frac{1}{3}\right) - 2\left(\frac{1}{\sqrt{2\pi}}\frac{3}{2}\right) > 0. \tag{5.7}$$

Since

$$\int_{-100}^{-1} \frac{1}{\sqrt{2\pi}} e^{-t^2/2}\, dt \approx .15866 < .16666\ldots = 1/6, \tag{5.8}$$

we have that $\frac{1}{\sqrt{2\pi}} e^{-(-1)^2/2} = \sqrt{\frac{e}{2\pi}} \approx .657745$ is a lower bound on $I_{\mathbf{G}^1}(1/6)$, and similarly since

$$\int_{-100}^{-1/2} \frac{1}{\sqrt{2\pi}} e^{-t^2/2}\, dt \approx .30854 < .33333\ldots = 1/3, \tag{5.9}$$

we have that $\frac{1}{\sqrt{2\pi}} e^{-(-1/2)^2/2} \approx .352065$ is a lower bound on $I_{\mathbf{G}^1}(1/3)$.

Combining these approximations we get

$$2I_{\mathbf{G}^1}\left(\frac{1}{6}\right) + 2I_{\mathbf{G}^1}\left(\frac{1}{3}\right) > 2 \cdot .65775 + 2 \cdot .35207 \approx 2.01964 > .7978 \approx 2\left(\frac{1}{\sqrt{2\pi}}\frac{3}{2}\right), \tag{5.10}$$

which proves that the Hutchings connectivity criterion is satisfied for equal volumes for spheres close enough to the Poincaré limit.

An argument like that used in $\mathbf{R}^3$ by Hutchings *et al.* proves that the minimizing enclosure for three equal volumes in these high-dimensional spheres is the standard double bubble; specifically, Cotton and Freeman ([10], or see Chapter 3) prove that in $\mathbf{S}^n$, an area minimizing double bubble that has both regions and the exterior connected must be standard.

By rotating and translating in $\mathbf{R}^{m+1}$ as necessary, we can recenter so that the origin is contained in determined by the $(m-2)$-dimensional singular set in the standard double bubble contains the origin. In addition we require that the first $n$ dimensions of $\mathbf{S}^m$ line up for all $m$. These are the dimensions which become $\mathbf{G}^n$ in the limit of projections. Since the standard double bubble in $\mathbf{S}^m$ is defined as a surface of revolution generated by the standard double bubble in $\mathbf{S}^{m-1}$, it is easy to see in the case $n = 2$ that the limit of the projections of the intersection of the standard double bubble with gthe first two dimensions of $\mathbf{S}^m$ the standard double bubble is the Y-shaped division of $\mathbf{G}^2$. This division is minimizing because it lifts to a minimizer in each of the spheres $\mathbf{S}^N$ as these spheres tend to the Poincaré limit. The same argument is in fact true when $n$ is greater than two, but it is easier to just observe that Y-shaped division of $\mathbf{G}^2$ lifts to the Y-shaped division of $\mathbf{G}^n$ and therefor the Y-shaped division of $\mathbf{G}^n$ must be minimizing. QEF

*Remark 5.1.* The proof shows that for large $N$, the least area division of $\mathbf{S}^N$ into three pieces of equal volume is given by a standard double bubble (in this case, three half-hyperspheres meeting along an $N-2$ sphere). The conjecture is that this is in fact the optimal division for all $N$.

**Charter** Characterize the perimeter minimizing double bubbles in the flat two-torus $\mathbf{T}^2$.

## 6.1 Introduction

Our Main Theorem (Section 6.7) shows that on the flat two-torus $\mathbf{T}^2$, the least-perimeter way to enclose and separate two prescribed areas is a double bubble of one of the six types of Figure 6.1: the standard planar double bubble $\Theta$, the band-lens $\Phi$, the symmetric two-component chain $\Omega$, the double band $\Xi$, the double hexagon $H$ (on the hexagonal torus only), or an octagon-square tiling $X$. We conjecture that the last of these never occurs as a minimizer.

**Conjecture 6.1.** The octagon-square tiling $X$ is never perimeter minimizing.

If Conjecture 6.1 is correct, Figure 6.2 shows which types prevail for which prescribed areas for four different tori.

The proof of the main theorem separates all candidates into five classes, and shows that the special double bubbles of Figure 6.1 are the only ones that are potentially perimeter minimizing: Propo-

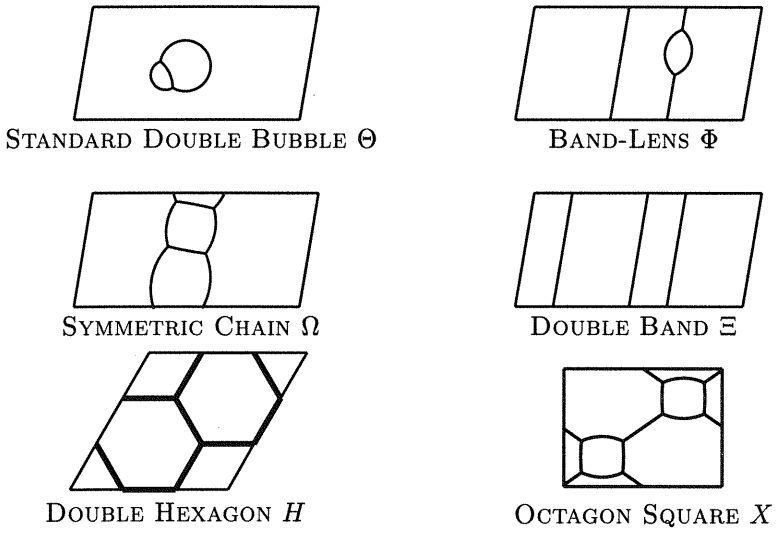

Figure 6.1: The six candidate perimeter- minimizing double bubbles on the flat two-torus.

sition 6.6 says that minimizers must be the double band or belong two one of four other topological classes; section 6.5.1 treats double bubbles in which all of the regions are contractible; section 6.5.2 treats double bubbles whose components taken together wrap around the torus, but whose components are all contractible; and section 6.5.3 treats double bubbles with one non-contractible region. The fourth class includes double bubbles that wrap around the torus in both directions. We call these candidates "tilings." Proposition 6.12 and 6.13 use the Euler characteristic of $\mathbf{T}^2$ and some basic facts about the regularity of minimizing bubbles to show that only two tilings are potential minimizers: the hexagon tiling $H$ on the hexagonal torus, and (perhaps) an octagon-square tiling. When it occurs as a minimizer, $H$ ties the double band $\Xi$ for perimeter. Section 6.6 gives formulas for the perimeter and area of the four finalists. Figure 6.2 gives a computational plot of the minimizing type for given areas.

We have been unable to prove Conjecture 6.1, which would eliminate the octagon-square and thus complete our analysis of tilings. Some tests using *Surface Evolver* suggest that deflating one of the separated bubble and expanding the other will reduce perimeter.

## 6.2 Definitions

Here we rigorously define, among other things, the classes of potential minimizers mentioned above. Thus, at this point it is necessary to introduce a convention that we use throughout the paper. Any double bubble partitions the space into three regions, but in naming and in speaking about these configurations, we will usually only look at two of these regions, $R_1$ and $R_2$ and not the third, which we call the *exterior*. So for example, $\Xi$, which might be otherwise be named the "triple band", is the double band. We should remark that on the torus the exterior need not be the largest of the three regions.

### 6.2.1 Tori and the Cylinder

**Definition 6.1.** A *flat two-dimensional torus* can be represented by a planar parallelogram with opposite sides identified, for which the shortest side is a shortest closed geodesic, and no interior angle is less than sixty degrees. In this paper we normalize so that the shortest closed geodesic has unit length. This also implies that the shortest side of the torus has length 1. We call the length of the other side $L$. If $L = 1$, there are two short directions, and on the hexagonal torus (see below) there are three short directions, one corresponding to the geodesic with homology $(-1, 1)$ .

**Definition 6.2.** The *hexagonal torus* can be represented either by a regular hexagon with opposite sides identified, or by a 60-degree rhombus with opposite sides identified.

**Definition 6.3.** The *flat infinite cylinder* can be represented as the surface contained between two identified infinite parallel lines in the plane. We take the distance between the two lines to be one.

### 6.2.2 Topological Definitions

**Definition 6.4.** A *double bubble* consists of two disjoint regions bounded by piecewise smooth curves, each of which may have multiple components.

**Definition 6.5.** A closed curve has *homology* $(p, q)$ if it wraps around the torus $p$ times in the short direction and $q$ times in the long direction, where $p$ and $q$ are signed to signify the orientation of the curve.

**Definition 6.6.** A *tiling* is a double bubble in which every component is contractible, including components of the exterior.

**Definition 6.7.** A *band* $\Pi$ is a non-contractible annulus. We often refer to the homology of a band, meaning the homology of one of its boundary components.

**Definition 6.8.** A *swath* $\Psi$ is a set of contractible components with non-contractible and connected closure $\overline{\Psi}$ and with non-contractible complement.

**Definition 6.9.** A *chain* is a non-contractible cycle of contractible components. Note that every swath contains at least one chain and that every chain is itself a swath. We often refer to the homology of the closure of the union of a chain, meaning the homology of one of its boundary components.

**Definition 6.10.** A *hexagon tiling* $\Upsilon$ is a tiling in which every component is a curvilinear hexagon.

**Definition 6.11.** An *octagon-square tiling* is a four-component tiling consisting of two curvilinear octagons and two curvilinear quadrilaterals. The two quadrilaterals are components of the same region.

### 6.2.3 Geometric Definitions

**Definition 6.12.** The *standard double bubble* $\Theta$ is comprised of three circular arcs meeting in threes at 120°, such that the curvature of the separating arc is the difference of the curvatures of the outer caps. For prescribed areas, $\Theta$ is unique up to congruence [34, Proposition 14.1].

**Definition 6.13.** The *double band* $\Xi$ is the union of two adjacent bands, each of which is bounded by two short geodesics.

**Definition 6.14.** A *symmetric chain* is a chain that is symmetric about a geodesic circle.

**Definition 6.15.** A *standard 2-component chain* $\Omega$ is comprised of six circular arcs meeting in threes at four common vertices at 120°, such that the curvature of each separating arc is the difference of the curvatures of the outer arcs (see Figure 6.1). Further, by Lemma 6.2 a minimizing standard 2-component symmetric chain has non-zero homology only in a shortest direction of the torus, and by Lemma 6.3 any such standard 2-component symmetric chain is unique up to isometries of the torus.

**Definition 6.16.** A *lens* is a pair of congruent circular arcs meeting at two vertices at 120°.

**Definition 6.17.** The *band lens* $\Phi$ is the union of a band and a lens, such that the boundary curves of the resulting configuration meet in threes at two vertices, at 120°. Further, by Proposition 6.6, a minimizing band-lens has non-zero homology only in a shortest direction of the torus and encloses the smallest area in the lens. By Lemma 6.19 any immersed band-lens is unique up to isometries of the torus.

**Definition 6.18.** The *hexagon tiling H* is a 3-component straight-edge hexagonal tiling on the hexagonal torus.

## 6.3 Existence, Regularity, and Basic Properties

This section provides existence and regularity (Proposition 6.1), a component bound (Proposition 6.2), and some easy consequences essential to all of our analysis.

**Proposition 6.1 (Existence and Regularity Theorem [32, 2.3 and 2.4] ).** In a smooth Riemannian surface S with compact quotient S/$\Gamma$ by the isometry group $\Gamma$, for any two areas $A_1$ and $A_2$ (whose sum is less than area(M)), there exists a least-perimeter enclosure of the two areas. This enclosure consists of smooth constant-curvature curves meeting in threes at 120° angles. All curves separating a specific pair of regions have the same curvature.

*Remark 6.1.* It follows that minimizing bubbles are connected, and that each component of either of the two regions or the exterior is adjacent to both others. Also, note that a double bubble satisfying regularity is in equilibrium, which means that the "first derivative" of its perimeter under any variation fixing areas is zero.

**Proposition 6.2 (Wichiramala Component Bound [38, Proposition 3.1] ).** Unless all three regions have equal pressure, each region of highest pressure has at most two components.

*Proof.* The topology of the torus does not interfere with the Wichiramala proof, as all variations used in his argument are strictly local. QEF

**Proposition 6.3.** The perimeter of a perimeter minimizing double bubble is at most three.

*Proof.* Three geodesic circles can enclose any pair of prescribed areas $A_1$, $A_2$. QEF

**Proposition 6.4.** No perimeter-minimizing tiling can occur on a torus with unit shortest side length and longest side length greater than $\sqrt{3}$.

*Proof.* Consider a torus with a tiling on it. Now, at each coordinate in the long direction of the torus, consider the unique non-contractible shortest closed geodesic associated with that coordinate. This shortest closed geodesic must intersect at least one curve at some point, otherwise the configuration could not be a tiling. Further, it must intersect some other or potentially the same curve in some other point, otherwise two components of the same region would be bordering themselves and the configuration could not be a minimizer. Now, considering the sum over all such shortest closed geodesics, we see that the configuration must span the long direction of the torus at least twice. Using the co-area formula, the configuration must have perimeter at least $2 \cdot L \cdot \sin(\theta) \geq \sqrt{3} \cdot L$. But by Proposition 6.3, $P \leq 3$, so $L \leq \sqrt{3}$. QEF

## 6.4 Topological Classification of Minimizers

In this section we build up several lemmas to prove two important propositions. Proposition 6.5 says that if a perimeter minimizing double bubble is not a tiling, and both regions and the exterior all have equal pressure, then the configuration is the double band. This is important in later sections. Proposition 6.6 is the backbone for the entire proof. It shows that all minimizing double bubbles must either be a tiling, a contractible double bubble, a swath, a band with some contractible blobs, or the double band. The next section and each of its subsections deals with the topological classes developed in this proposition.

**Lemma 6.1.** In a partition of the torus into piecewise smooth non-contractible components, each component is a band.

*Proof.* Every closed curve in the boundary must be non-contractible. Hence the boundary must consist of disjoint closed curves, all in the same non-trivial homology class. It follows that each component is a band. QEF

**Lemma 6.2.** Any non-contractible component, $A$, in a minimizing double bubble on the torus must either be a band or have contractible complement.

*Proof.* If the complement of $A$ is contractible, we are done. Suppose that the complement of $A$ is not contractible. If there are any contractible components of the complement inside of $A$, merge them with $A$. Now we have a partition of the torus into two non-contractible regions, and by Lemma 6.1, $A$ must be a band or a punctured band (since we filled the holes in $A$). But since A is part of a minimizing double bubble, by Remark 6.1 $A$ must be a band. QEF

**Lemma 6.3.** Given a chain or band that is part of a minimizing double bubble, and with homology $(p, q)$, $|p| \leq 1$ and $|q| \leq 1$.

*Proof.* Since a band and the closure of the union of a chain are simply annuli, each chain or band has

at least two disjoint, non-contractible boundary curves. Thus, if $|p| > 1$ or $|q| > 1$ then the perimeter is at least four. By Proposition 6.3 the double bubble cannot be a minimizer. QEF

**Lemma 6.4.** A perimeter minimizing double bubble on the torus, together with its exterior, has at most three disjoint bands or chains. Further, if there are three, then they must all be bands, and the double bubble must be the double band.

*Proof.* Since a band and the closure of the union of a chain are non-contractible annuli, each chain or band has at least two non-contractible boundary curves, each of length at least one. Since each such boundary curve borders at most two such annuli, if there are $n$ annuli, there will be at least $n$ such non-contractible boundary curves. Thus, by Proposition 6.3, $n \leq 3$. Further, if $n = 3$, the perimeter of the double bubble is greater than three unless each of the non-contractible boundary curves is a geodesic in the short direction of the torus and if there is no other boundary, so that the double bubble must be the double band.

QEF

**Proposition 6.5.** A perimeter minimizing double bubble of three equal pressures is either a tiling or the double band.

*Proof.* Assume that the double bubble is not a tiling, so that there is at least one non-contractible component. By Lemma 6.2, this component is either a band, or its complement is contractible. The latter is impossible, for it would be a planar polygon with interior angles of 240 degrees.

Thus, the configuration must contain at least one band, bounded by piecewise geodesic curves with interior angles of 120 degrees. Lifting to the plane shows that the boundary curves must be smooth closed geodesics.

Now, denote the rest of the boundary by $X$. If $X$ is contractible, merely slide $X$ up against the band to contradict regularity. If $X$ is non-contractible, then the double bubble plus its exterior must have at least three bands. By Lemma 6.4, the double bubble must be the double band.

QEF

**Proposition 6.6.** All minimizing double bubbles on the torus must be either a contractible double bubble, a tiling, a swath, a band adjacent to a set of components whose union is contractible, or the double band (after perhaps relabelling the two regions and the exterior).

*Proof.* We may assume that every non-contractible component is a band, since otherwise by Lemma 6.2 it is the complement of a contractible double bubble.

If the double bubble plus its exterior has no bands, then all regions are contractible, and thus by definition the double bubble is a tiling.

If the double bubble plus its exterior has one band, then the complement is a set of contractible components. But the closure of the union of this set of components, being the complement of a band, is itself a band, and thus non-contractible. Thus, by definition the double bubble is a swath.

If the double bubble plus its exterior has two bands, consider the complement, C, of the closure of the union of the two bands. If C is non-contractible, then we have a partition of the torus into non-contractible regions, and thus, by Lemma 6.1 this complement is also a band. But since the two bands are the only non-contractible components, we must have a configuration with two bands and a swath. But the swath contains at least one chain, and so the double bubble plus its exterior contains one chain and two bands, which impossible by Proposition 6.4. So the complement of the closure of the union of the two bands must be contractible. And thus the double bubble must be a band adjacent to a set of components whose union is contractible

If the double bubble plus its exterior has three or more bands, then by Proposition 6.4, the double bubble must be the double band.

QEF

## 6.5 The Four Classes with Contractible Components

By Proposition 6.6, all minimizing double bubbles on the torus must be either a contractible double bubble, a tiling, a swath, a band adjacent to a set of components whose union is contractible, or the double band. While the double band describes a specific geometric configuration, each of the remaining possibilities is merely a topological class of configuration. In this section we identify the minimizer in each of these four remaining topological classes: the standard double bubble among contractible double bubbles (Proposition 6.1), a two-component symmetric chain among swaths (Proposition 6.10), and the band-lens among bubbles with a single band (Proposition 6.11) Proposition 6.12 and 6.13 use the Euler characteristic of $\mathbf{T}^2$ and some basic facts about the regularity of minimizing bubbles to show that only two tilings are potential minimizers: the hexagon tiling $H$ on the hexagonal torus, and (perhaps) an octagon-square tiling.

### 6.5.1 Contractible Double Bubbles

Proposition 6.1 uses the result from $\mathbf{R}^2$ that perimeter-minimizing double bubbles are standard [24], to show that the only potential minimizer among contractible double bubbles is the standard double bubble.

**Lemma 6.1.** The perimeter of a standard double bubble is greater than Pi times its diameter: $P > \pi D$.

*Proof.* We obtain a formula for $P/D$ as a function $f(\theta)$, where $\theta$ is the angle between the interior arc of the standard double bubble and the chord that connects its endpoints. Then we show $f(\theta) > \pi$ for the entire domain $0 < \theta \leq \pi/3$.

Let $r_1, r_2, c_1, c_2$ be the radii and centers of the longer and shorter exterior arcs of the standard double bubble, respectively. Then the diameter is the sum of $r_1$, $r_2$, and the distance between $c_1$ and

$c_2$:

$$D = r_1 + r_2 + r_1 \cos(\pi/3 - \theta) + r_2 \cos(\pi/3 + \theta).$$

Applying the formula for radii in Section 6.6.1, we obtain a expression that can be solved for $C$, the length of the separating chord:

$$D = C((1 + \cos(\pi/3 - \theta))/(2\sin(2\pi/3 + \theta)) + (1 + \cos(\pi/3 + \theta))/(2\sin(2\pi/3 - \theta))).$$

Substituting for $C$ in the equation for perimeter in Section 6.6.1, we obtain the desired function in $\theta$:

$$f(\theta) = P/D = (8\pi \sin\theta\cos\theta + 3\sqrt{3}\theta)/(6\sin\theta\cos\theta + 3\sin\theta)$$

.

To show $f(\theta) \geq \pi$ is equivalent to showing

$$8\pi \sin\theta\cos\theta + 3\sqrt{3}\theta \geq \pi(6\sin\theta\cos\theta + 3\sin\theta).$$

Moving the terms to the left hand side and using the identity $\sin(2\theta) = 2\sin\theta\cos\theta$, we obtain the equivalent inequality

$$\pi\sin(2\theta) + 3\sqrt{3}\theta - 3\pi\sin\theta > 0. \qquad (*)$$

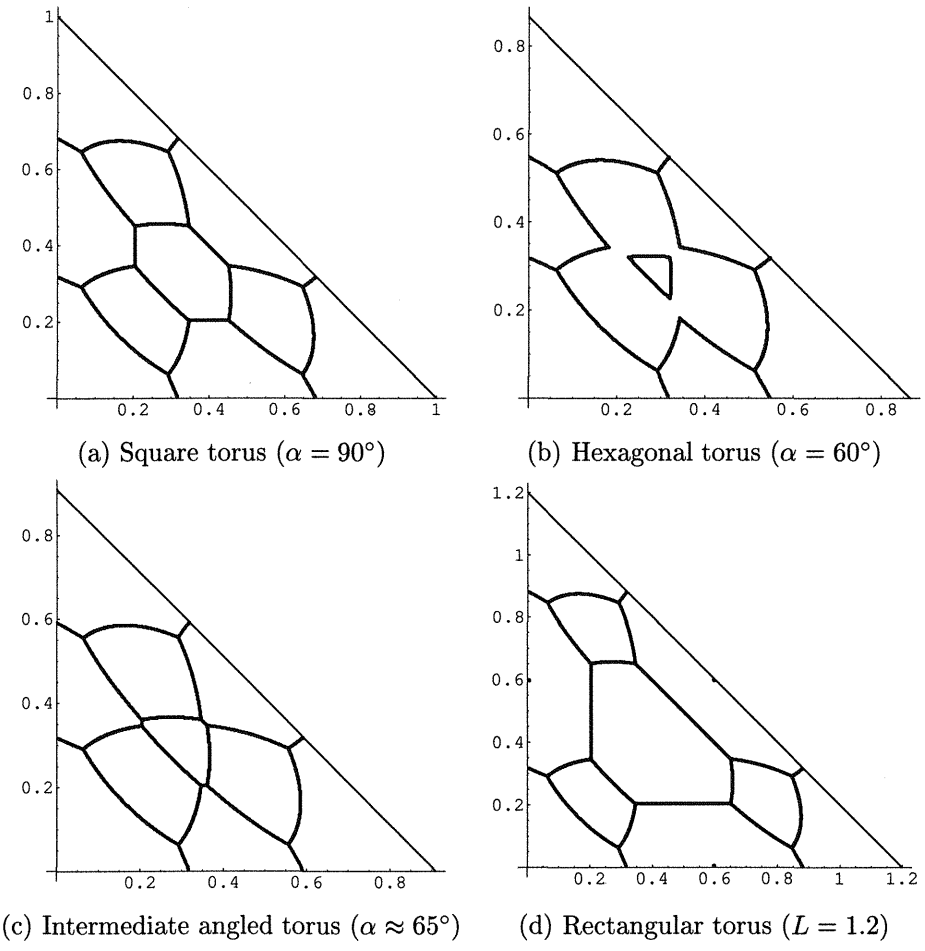
We view the left hand side $L$ as a function of $\theta$; its second derivative is

$$-4\pi\sin(2\theta) + 3\pi\sin\theta = \pi\sin\theta(-8\cos\theta + 3).$$

For $\theta \in (0, \pi/3)$, we have $\sin\theta > 0$ while $\cos\theta > \cos(\pi/3) > 3/8$. Hence, this last expression is strictly negative, and the left hand side $L$ of $(*)$ is strictly concave for $\theta \in [0, \pi/3]$. Because $L$ equals 0 when $\theta$ is at the endpoints of this interval, it must be positive along the interior of this interval, as desired.

QEF

**Proposition 6.1 (Generalization of [28]).** The only possible minimizer among contractible double bubbles is the standard double bubble.



*Proof.* Assume that there is a perimeter minimizing contractible double bubble $\Sigma$ enclosing areas $A_1$ and $A_2$ that is not the standard double bubble. By [24], the unique perimeter-minimizing solution in $\mathbf{R}^2$ for the same prescribed areas is a standard double bubble $\Theta$. If $\Theta$ fits on the torus, it will beat $\Sigma$, since it beats $\Sigma$ in the plane. Therefore $\Theta$ does not fit on the torus.

But since $\Theta$ does not fit on the torus, then its diameter must be greater than the shortest side length of the torus (otherwise, it would fit with the axis of symmetry in any direction). But, by Lemma 6.1, $P > \pi \cdot D > 3$, and thus by Proposition 6.3, $\Theta$ is not a minimizer.

QEF

### 6.5.2 Swaths

By Proposition 6.5, minimizing swaths must be chains consisting of two or four components. By Proposition 6.8, asymmetric chains cannot be minimizers since they have perimeter greater than three. Finally, by Proposition 6.9, minimizing symmetric chains can have only two components.

(a) Square torus ($\alpha = 90°$)

(b) Hexagonal torus ($\alpha = 60°$)

(c) Intermediate angled torus ($\alpha \approx 65°$)

(d) Rectangular torus ($L = 1.2$)

***Square Torus.*** *Twenty-one smooth-looking curves divide the space into ten regions. The approximate locations of the four vertices in the lower left corner are* $\approx (0.34596, 0.20352)$, $\approx (0.20352, 0.34596)$, $\approx (0.06, 0.29)$, *and* $\approx (0.29, 0.06)$. *The two curves parallel to the axes are* $A_1$ *and* $A_2 = (\frac{8\pi}{3} - 2\sqrt{3})^{-1} \approx 0.2035$, *respectively. The curves that touch the axes in the lower left corner touch at* $\frac{1}{\pi} \approx 0.3183$.

***Hexagonal Torus.*** *Eighteen smooth-looking curves divide the space into eight regions.*

Figure 6.2: How minimizing double bubble types depend on the prescribed areas for four flat tori

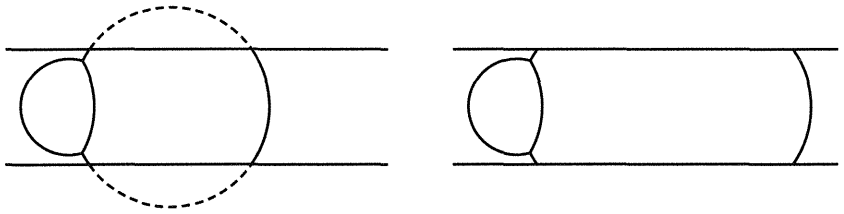


Figure 6.3: On the cylinder, we can make simple adjustments when the standard double bubble does not fit; the same argument does not work on the torus.

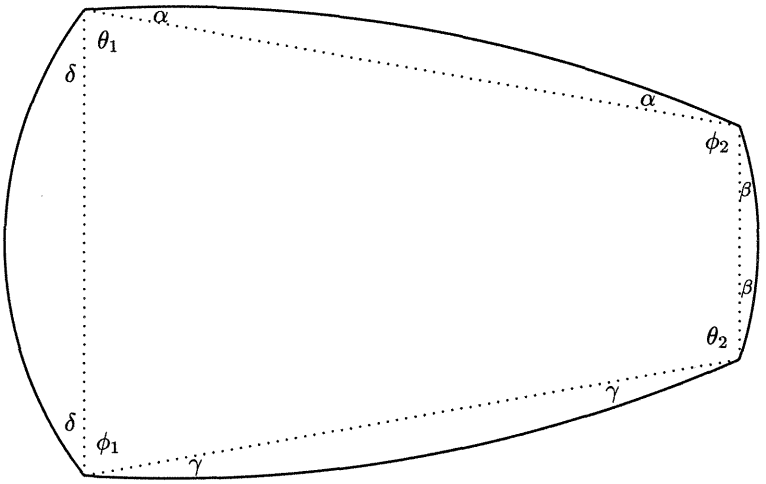

Figure 6.4: Important angles in a regularity satisfying quadrilateral

**Lemma 6.2.** If a component of a region is a curvilinear quadrilateral, then the quadrilateral is cyclic (i.e., the vertices lie on a common circle).

*Proof.* We must show that opposite angles sum to 180°. Consider the chords joining consecutive vertices as in Figure 6.4.

Since each boundary curve must meet its corresponding chord at equal angles $\alpha, \beta, \gamma, \delta$ and these curves meet each other at 120° angles, we have the following set of equations:

$$2(\alpha + \beta + \gamma + \delta) + \theta_1 + \theta_2 + \varphi_1 + \varphi_2 = 480°;$$

$$\theta_1 + \theta_2 + \varphi_1 + \varphi_2 = 360°.$$

From this we easily get $\alpha + \beta + \gamma + \delta = 60°$. Summing opposite angles of the component yields

$$\alpha + \beta + \gamma + \delta + \theta_1 + \theta_2 = 240°;$$

$$\alpha + \beta + \gamma + \delta + \varphi_1 + \varphi_2 = 240°.$$

Whence, we get $\theta_1 + \theta_2 = \varphi_1 + \varphi_2 = 180°$ QEF

*Remark 6.2.* The center of the circle is of course where the two bisectors of any two nonparallel sides intersect. The following Lemma shows that Figure 6.4 describes the general case.

**Lemma 6.3.** The vertices of a curvilinear quadrilateral component of a regularity satisfying planar double bubble form an isosceles trapezoid. Furthermore, if the trapezoid is not a rectangle, then the two boundary components corresponding to the parallel sides of the trapezoid lie on the same circle.

*Proof.* We reflect across the line of symmetry of each arc to see that the component must be an isosceles trapezoid.

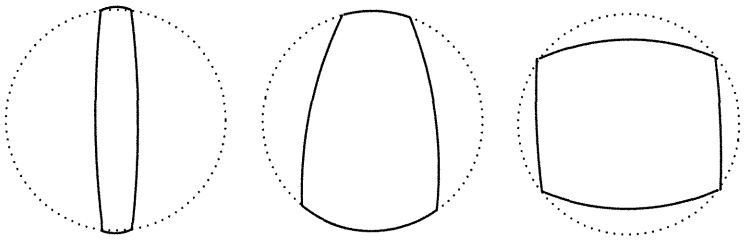

Figure 6.5: Quadrilateral components

Suppose it is not a rectangle. Since the arcs corresponding to the two non-parallel sides make a 120° angle with the longer of the two parallel sides, they will also make a 120° interior angle with the completion of this arc to a circle. Since the component is not rectangular, any arc other than these two with the correct curvature which makes a 120° angle with one of the non-parallel arcs will not make a 120° angle with the other. We therefore have the desired result.

QEF

*Remark 6.3.* In the previous two lemmas it is actually enough to have two parallel sides be circular arcs of the same curvature, the other two boundary curves can then be arbitrary smooth curves. This is relevant for example in Figure 2 of [41].

**Proposition 6.2.** In a regularity satisfying double bubble, then arcs $\lambda_1$ and $\lambda_2$ connecting to one of the two parallel sides of a quadrilateral component that is not a rectangle lie on the same circle.

*Proof.* Consider the digon obtained by replacing $\mu_2$ with the completion of the arc containing $\sigma_1$ and $\sigma_2$. This gives us two boundary components of some standard double bubble. Since pressures add, we can complete this double bubble with the correct circular piece. Since, locally, the original quadrilateral component looks like the standard double bubble, the boundary curves connecting to it lie on the same circle. QEF

**Proposition 6.3.** Unless both regions and the exterior all have equal pressure, every component

of each lowest pressure region of a regularity satisfying double bubble that is not a tiling is non-contractible.

*Proof.* Suppose a component of the lowest pressure region is contractible. Then it is must be a curvilinear $n$-gon, where $n$ is strictly greater than six, since each edge of a lowest pressure region must either be straight or bow into the region, and not all the edges are straight, leaving room for 120°angles only if there are more than six edges. By regularity, consecutive sides must border different regions, so $n$ must be even.

By Proposition 6.2, a region of highest pressure, which we will call $R_1$, has at most two components. Since every component of a highest pressure region can have at most four vertices, $R_1$ can have at most eight vertices.

Therefore, there is exactly one lowest pressure region, and it has exactly eight edges, otherwise $R_1$ would have too many vertices.

Furthermore, we note that none of the components of $R_1$ can be digons, since this would leave six vertices for the other component of $R_1$, which as we have noted is too many. Thus, there are two quadrilateral components of $R_1$ each bounded by a pair of sides on the octagon.

By the results of the previous subsection, the double bubble can not be contractible. Therefore at least one of the quadrilateral components must wrap around the torus. If only one of the quadrilateral components wraps around the torus, we get the absurd configuration in Figure 6 (a), in which two pieces of the quadrilateral that does not wrap are disconnected from one another. If both of the components wrap around the torus, either they wrap around different sides, in which case the configuration is a tiling (the octagon square actually – but at any rate, not addressed in this proposition) or we have a configuration like that of Figure 6 (b).

As illustrated, each of the quadrilaterals must admit the inscription of a rectangle on their vertices, otherwise by Lemma 6.3 the sides which do not border the low pressure octagon would lie on the same circle, and by Proposition 6.2 the two adjacent edges of the low pressure octagon would

A. B.

Figure 6.6: Two absurd low pressure components

have to lie on a circle as well, which is ridiculous.

It now follows from a standard fact about parallel lines and transversals, that the edge of the low pressure octagon that joins the two edges shared with the quadrialteral must meet one of these edges at an acute angle. But this contradicts regularity, proving the proposition.

QEF

**Proposition 6.4.** In a perimeter minimizing swath containing a chain $K$, no component of $K$ is a digon.

*Proof.* Suppose $K$ contains a digon $D$. Since $D$ is adjacent to only two components, if it occurs in $K$, it must be adjacent to components of the same region. This requires either that four arcs meet at a point, or that some region is separated from itself by arcs which could be removed to reduce perimeter. In either case, the original configuraion can not have been minimizing, proving the claim. QEF

**Proposition 6.5.** Minimizing swaths must be chains with a total of two or four components from two regions.

*Proof.* By Proposition 6.5 the three regions in a minimizing swath $\Psi$ do not have the same pressure. Furthermore, by Proposition 6.3 a least pressure region does not appear in the swath. Also, the least pressure region is unique since a swath contains components from two regions. Consider a chain $K$ in $\Psi$. The components in $K$ must alternate between two higher pressure regions $R_1$ and $R_2$. By Proposition 6.2 the region of highest pressure, $R_1$, has at most two components, so $K$ has exactly 2 or 4 total components.

Suppose $K$ has four components. Then any additional components of the $R_2$ in the swath have to be adjacent to components of $R_1$ in the chain (since by definition, the union of swath components is connected). However, this is impossible since components of $R_1$ already have four vertices and a convex non-polygonal component has at most four vertices. Thus, a swath containing a four component chain must be a four-component chain.

Next, suppose $K$ has two components. Further, suppose the swath contains additional components. Then there is some component adjacent to the chain (otherwise the closure of the swath is disconnected). As before, there can be no extra components adjacent to the component of $R_1$ in $K$. So, there is a component of $R_1$ adjacent to the component of $R_2$ in $K$. If this is the only other component in the swath, then it is a digon which can be eliminated by sliding it along $\partial R_2$

Figure 6.7: Extra digons do not attach to the symmetric chain

until it touches another component or a vertex creating an illegal singularity (see Figure 6.7). If, instead, there is another component of $R_2$ attached to the second component of $R_1$, then it is either a digon or it is attached to another component of $R_1$. In the case of the former, we can eliminate this configuration using the same sliding technique. The latter case is impossible since, by Proposition 6.2 it would have to be attached to an existing quadrilateral component of $R_1$. This contradicts our assumption that the swath contains additional components; therefore, a minimizing swath is a chain with two or four components. QEF

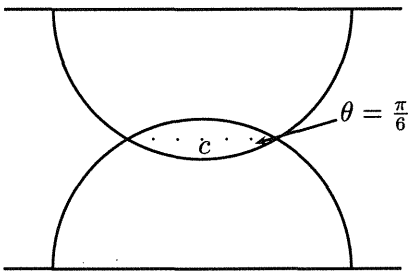

Figure 6.8: Chain violates regularity.

**Proposition 6.6.** In a symmetric 2-component chain where the arcs separating each component from the exterior lie on the same circle, the total perimeter of the chain is strictly greater than 3.

*Proof.* In a cylinder with geodesic circle of length 1, we can parameterize a symmetric chain composed of two components, by two parameters: the length $C$ of a chord connecting vertices shared by both components of the chain, and the angle $\theta$ between this chord and the boundary curve con-

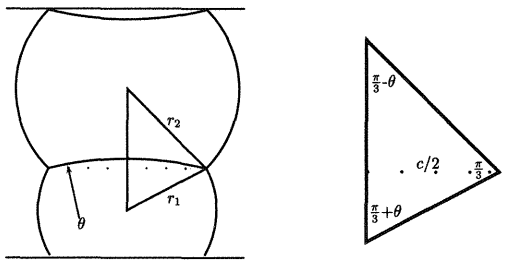

Figure 6.9: Chain constraints.

necting the same vertices. Here $\theta$ must range between 0 and $\frac{\pi}{6}$ radians, since at $\theta = \frac{\pi}{6}$, the chain violates regularity (see Figure 6.8).

At an endpoint of $C$ we draw the radii $r_1$, $r_2$ of the two exterior arcs of the chain that meet at this point (See Figure 6.9). Connecting the opposite endpoints of these radii (the centers of the circular arcs), we have a set of triangles from which we can compute a value of $C$ for a given $\theta$.

Using the law of sines in Figure 6.9, we discover that $\frac{\sin\frac{\pi}{3}}{\frac{1}{2}} = \frac{\sin(\frac{\pi}{3}-\theta)}{r_1}$. Since, $\sin(\frac{\pi}{3}+\theta) = \frac{\frac{C}{2}}{r_1}$, we get

$$\frac{\sin(\frac{\pi}{3}-\theta)}{\sqrt{3}}\sin(\frac{\pi}{3}+\theta) = \frac{C}{2}$$

Further simplification yields:

$$C = \frac{\sqrt{3}}{2} - \frac{2}{\sqrt{3}}\sin^2\theta$$

We can obtain a lower bound on the perimeter of the chain by approximating the length of each arc by its corresponding chord. This length is exactly $2C + 2$. Since $C$ is decreasing in $\theta$ and $C(\frac{\pi}{6}) = \frac{1}{\sqrt{3}} \approx .577$, we conclude that perimeter is greater than 3. By scaling, we get the result for arbitrary cylinders. QEF

**Proposition 6.7.** For any symmetric chain $\Sigma$ consisting of four components, there exists a two-component chain with equal perimeter that is similar to an adjacent pair of components in $\Sigma$.

*Proof.* Since alternating components of a 4 component symmetric chain are congruent (this comes from symmetry about a line perpendicular to the geodesic circle), we construct a two-component chain by taking adjacent components of $\Sigma$ and scaling up by a factor of 2. The perimeter remains constant since we doubled half of the original perimeter of $\Sigma$. Also, by construction, the chain is similar to $\Sigma$. QEF

**Proposition 6.8.** All asymmetric chains have perimeter greater than 3.

*Proof.* By Lemma 6.3, at least one component of an asymmetric chain must have vertices that form a non-rectangular isosceles trapezoid, and the arcs separating this component from the exterior lie on the same circle. By Proposition 6.2, the same is true for the other components in the chain.

We can expand the cylinder continuously, rotating components as needed, until the chain fits symmetrically along a geodesic circle (see Figure 6.10) . By Propositions 6.6 and 6.7, the perimeter of the chain is greater than three times the side length of the expanded cylinder. Hence the perimeter of the chain is greater than 3, and by Proposition 6.3, we have the desired result. QEF

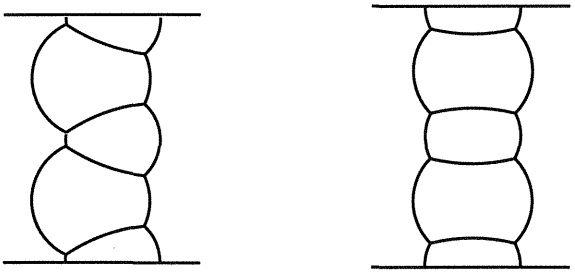

Figure 6.10: Rotate bubbles and stretch cylinder to make asymmetric chain symmetric.

**Proposition 6.9.** A four-component symmetric chain cannot be a minimizer.

*Proof.* Suppose that a four component chain $\Sigma$ is a minimizer for some pair of prescribed volumes. Let $R_1$ be the region of highest pressure. Since each pair of vertices shared by adjacent components is separated by the same horizontal distance, we can rearrange the components so that those belonging to the same region are adjacent (see Figure 6.11). Upon careful relabelling of the regions, area is maintained and we have violated regularity, a contradiction. QEF

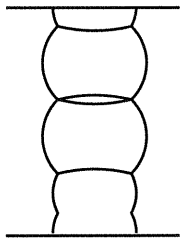

Figure 6.11: A regularity violating rearrangement of the components of a four component symmetric chain.

**Proposition 6.10.** The only potential minimizer among `sws` is a standard two-component symmetric chain.

*Proof.* By Proposition 6.5, minimizing swaths must be chains consisting of two or four components. By Proposition 6.8, asymmetric chains cannot be minimizers since they have perimeter greater than 3. Finally, by Proposition 6.9, minimizing symmetric chains can have only two components. QEF

**Conjecture 6.2.** A minimizing standard two-component symmetric has non-zero homology only in the short direction of the torus.

(This can be checked computationally.)

### 6.5.3 A Single Band Adjacent to a Set of Components with Contractible Union

Proposition 6.11 uses regularity and the results of Proposition 6.2, and Proposition 6.3 to show that the only minimizer in the class of double bubbles with a single band adjacent to a set of components with contractible union is the band-lens, $\Phi$.

We will consider a proposed minimizer $\Sigma$ with regions $R_1$, $R_2$ and the exterior, such that $R_1$ contains a band, $\Pi$.

In several of the proofs, we do some area maintaining deformation which reduces perimeter, or which causes the bubbles to bump up against one other, violating regularity. In either case, the original configuration was not a minimizer.

**Lemma 6.4.** The pressure difference between $R_1$ and the exterior must be zero, i.e. all curves separating $R_1$ from the exterior must be straight lines.

*Proof.* Consider a curve separating the band, $\Pi$, from the exterior. If it is a straight line segment, the proof is complete, since the all curves separating $R_1$ from the exterior have the same curvature.

If the curve to be considered has nonzero curvature, continuously straighten the curve to reduce perimeter, and slide one of the sides of $\partial\Pi$ in order to maintain area. Either we will be able to straighten all such pieces while reducing perimeter, or we will first cause a violation of regularity.

Note that this implies that all curves enclosing components of $R_2$ must have the same curvature.

QEF

**Lemma 6.5.** In the class of double bubbles with a single band, $R_2$ must have a higher pressure than both $R_1$ and the exterior.

*Proof.* Assume not. Then components of $R_2$ are either bounded by straight lines, or are concave with respect to both $R_1$ and the exterior.

Now because the blob is contractible, we can create a closed geodesic $T$ which is not in $\Pi$ and which is not adjacent to any region but the exterior. If we slide $T$ towards one of the blobs, they

must eventually collide. Since all components are either concave or bounded by straight lines, the collision either occurs at a point which must be an illegal singularity (i.e. it cannot be 3 smooth curves meeting a 120 degree angles), or in a line. If it is in a line, the line with which $T$ collided must be a complete closed geodesic, otherwise it would contain an illegal singularity. This configuration either is the meridional band solution $\Xi$, or $\Xi$ beats it. QEF

**Corollary 6.1.** $R_2$ has at most two components.

*Proof.* This follows directly from the previous lemma and Proposition 6.2. QEF

**Corollary 6.2.** All contractible components of a double bubble with a single band consist of components of $R_2$.

*Proof.* By Lemma 6.5 and Lemma 6.4, $R_1$ and the exterior have equal, lowest, pressure. Thus, by Proposition 6.3, their components must be non-contractible. Hence only components of $R_2$ can be contractible. QEF

**Proposition 6.11.** The only potential minimizer among double bubbles with a single band is the band-lens $\Phi$.

*Proof.* By Proposition 6.2, $R_2$ (the region without the band) has either one or two components.

If $R_2$ has a single component, by Corollary 6.2, this is the only contractible component in the double bubble. The side of $\partial\Pi$ which does not intersect $\partial R_2$ is, by Lemma 6.4, a straight line; and, by the definition of a band, closed. Now consider the side which intersects $\partial R_2$. Again by Lemma 6.4, the curve which separates $\Pi$ from the exterior is a straight line. Now, rotate the component until this line lies on a geodesic circle, while sliding the boundary of $\Pi$ to maintain area. This will always save perimeter or cause a violation of regularity. Now the only way in which curvature and regularity conditions can be satisfied is if we have the standard band-lens solution.

If $R_2$ has two components, by Corollary 6.2 these are the only contractible components that share boundary with $\Pi$. Further, either both components are on the same side of $\partial\Pi$ or they are on

opposite sides of $\partial\Pi$.

Assume they are on opposite sides of $\partial\Pi$ and consider one of these sides. By Lemma 6.4, any curve which separates $\Pi$ from the exterior is a straight line. Now, rotate the component until this curve lies on a geodesic circle, while sliding the boundary of $\Pi$ to maintain area. This will always save perimeter or cause a violation of regularity. Repeat for the other side. Move one of the components so that they both lie on the same side. Now we can slide them, while maintaining area, until there is a violation of regularity, showing the configuration to be bad. If the components are too large to fit on the same side, the configuration must have perimeter greater than 3, which by Lemma 6.3 is a contradiction.

If both components of $R_2$ are on the same side of $\partial\Pi$, we must consider their structure in a bit more detail. By Lemma 6.4, any curve which separates $\Pi$ from the exterior is a straight line. Now, each component must meet the line of $\partial\Pi$ in two frames where three curves meet at 120 degree angles. Now rotate and shift the two components until all 4 frames and thus the lines connecting them lie along a shortest closed geodesic. We can maintain area by sliding the boundary of $\Pi$, and we will either have a violation of regularity, or save perimeter by reducing the original configuration to a configuration in which connecting lines are part of a shortest closed geodesic. If we have the latter, slide the two components, while maintaining area, until there is a violation of regularity showing the configuration to be bad.

Thus, the double bubble must be the band-lens, $\Phi$. QEF

**Lemma 6.6.** In a minimizing band-lens, the band must have non-zero homology only in a short direction of the torus and the lens must enclose the smallest of the three areas.

*Proof.* First we show that any pair of areas that can be enclosed by a band-lens along the long direction can be enclosed by a band-lens in the shorter direction. Assume not. Then either the lens is too long or too wide to fit in the short direction. If it is too long to fit in the shorter direction, then the double bubble will have perimeter greater than three, and, by Proposition 6.3, it cannot be a

minimizer. If the lens is too wide, then the geodesic not adjacent to the lens cannot get close enough to make the band thin enough. But if this happens in the short direction, then it will certainly happen in the long direction where there is less leeway.

It is easy to see that the lens must enclose the smallest of the three possible areas. This is because the other two regions can exchange area for free, but the perimeter of the band-lens is strictly increasing with the area of the lens. QEF

### 6.5.4 Tilings

Propositions 6.12 and 6.13 show that the only minimizing tilings are the hexagon tiling $H$ and possibly an octagon-square tiling. The proofs use pressure conditions, the Wichiramala component bound, and a variational argument, as well as elementary graph theory and plane geometry.

**Lemma 6.7.** A component $C$ of a perimeter minimizing tiling $\Sigma$ must be a curvilinear polygon with an even number of edges greater than or equal to four.

*Proof.* Of course, by regularity we know that if $x$ and $y$ are adjacent edges of $C$, then $C$ is adjacent to different regions along each side. This implies that the regions adjacent to $C$ must alternate with the edges of $C$, which is only possible if $C$ has an even number of edges.

To complete the proof, we must show that a digon cannot occur in a tiling solution. To do this, note that by regularity a component that is a digon must be a lens. This lens either lies on a pair of straight lines, or on a pair of curves which lie on the same circle.

Either way, we can slide the lens along the lines or arcs without changing perimeter or area. Then either we reach a violation of regularity, or we can slide the lens around the torus without bumping into anything. If the latter is the case, either the lens lies on a free circle, which can be translated to cause a violation of regularity, or the lens lies on a free, closed geodesic. The latter implies that $\Sigma$ contains a non-contractible component (actually, two), which contradicts our hypothesis. QEF

**Lemma 6.8.** If a tiling of a torus has vertices of degree 3, the average number of edges per component is exactly 6.

*Proof.* The Euler characteristic on the torus is $v - e + c = 0$, where $v$ is the number of vertices, $e$ is the number of edges, and $c$ is the number of components. Now, let $n$ be the average number of edges per component. Then $c = \frac{2}{n}e$, since each edge is adjacent to two components, and each component averages $n$ edges. We also know that $v = \frac{2}{3}e$, since each edge is adjacent to two vertices, each vertex is adjacent to three edges. Substituting into the Euler formula, we obtain $(\frac{2}{3} - 1 + \frac{2}{n})e = 0$, from which we obtain $n = 6$. QEF

**Proposition 6.12.** A perimeter-minimizing tiling $\Sigma$ is either a straight-line hexagon tiling, or an octagon square tiling (a tiling in which the region of highest pressure consists of two curvilinear quadrilaterals, and the other two regions are curvilinear octagons).

*Proof.* If the three regions of $\Sigma$ have equal pressure, then all boundary curves are straight lines. Now, the only straight-edged polygon with 120° interior angles is the hexagon, so by regularity all components must be hexagons.

If the three regions of $\Sigma$ do not have equal pressure, then there is a region $R_1$ with pressure at least as low as all other regions, and a region $R_2$ with pressure at least as high as all other regions. For the following vertex-counting argument, note that by regularity each vertex of $\Sigma$ must be a boundary constituent in components of all three regions.

Now, every boundary curve of an $R_1$ component is either a straight line or bows in, so by regularity every $R_1$ component must have at least eight sides. Then $R_1$ components must each contain at least eight vertices in their boundaries, so $\Sigma$ must contain at least eight vertices.

Similarly, every boundary curve of an $R_2$ component is either a straight line or bows out, so by regularity and by Lemma 6.7, every $R_2$ component must have exactly 4 sides and 4 vertices. Furthermore, we know by the Wichiramala Component Bound that $R_2$ has at most 2 components.

Then $R_2$ components are adjacent to at most $(2\ components)(4\frac{vertices}{component}) = 8\ vertices$, so $\Sigma$ can contain at most 8 vertices.

Thus $\Sigma$ must contain exactly eight vertices, and $R_2$ must consist of exactly two four-sided components. Now the components of the remaining region, $R_3$, contain a total of eight vertices in their all boundaries. are adjacent to eight vertices, so $R_3$ must have either one 8-sided component or two four-sided components. But by Lemma 6.8, the average number of sides per component must be exactly six. The only combination that satisfies this condition is for $R_3$ to have one eight-sided component. This implies by regularity that $R_3$ must have less pressure than $R_2$, since a region of highest pressure cannot have eight-sided components.

Thus if the three regions of $\Sigma$ do not have equal pressure, there is a unique region of highest pressure consisting of two curvilinear quadrilaterals, while the other two regions each consist of a single curvilinear octagon. QEF

**Lemma 6.9.** The number of components in a minimizing hexagon tiling $\Upsilon$ must be a multiple of three, since each region must have the same number of components.

*Proof.* By regularity, every vertex in $\Upsilon$ must be adjacent to exactly 1 component from each of the three different regions. Then every region has exactly the same number of vertices lying in the boundaries of its components. By definition, every component in a hexagon tiling has the same number of vertices (6) in its boundary. Then every region must have the same number of components. Since there are three regions, the total number of components must be a multiple of three. QEF

**Lemma 6.10.** A hexagon tiling with 9 or more components is not a perimeter minimizer.

*Proof.* We first fix some notation. Given a tiling $\tau_0$ with $t = 3n$ hexagons on the 2-torus, the claim is that the total perimeter of the tiling is greater than three.

Extend the tiling $\tau_0$ of the torus to a tiling $\tau$ of the plane, coloring the plane in $t$ colors in the

natural manner. Without loss of generality, we may assume that any segment in the perimeter of the tiling forms an angle of $0$, $\pi/3$, or $2\pi/3$ with a horizontal line in the plane.

We can travel from any fixed hexagon $H$ in the tiling to a neighboring hexagon in any of six *directions*, which we label `N`, `NE`, `SE`, `S`, `SW`, `NW` in clockwise order, where by travelling in the `N` direction, we travel to the hexagon which borders the top edge of $H$. Similarly, we can travel from any vertex in the tiling to a neighboring vertex in several possible directions, in three directions from any fixed vertex but in six directions total. We label these directions `e`, `se`, `sw`, `w`, `nw`, `ne`, where any rays in these directions make clockwise angles of $0$, $\pi/3$, ..., $5\pi/3$ with the horizontal ray pointing to the right.

The first major step is to finding a 'gridlike' fundamental domain

Suppose that the two hexagons $A_1$ and $A_2$ have the same color, and that we can travel from $A_1$ to $A_2$ via some sequence $\mathcal{S}$ of directions $(d_1, \ldots, d_r)$. ($A_1$ and $A_2$ must be associated with different fundamental domains, since by choice each component of $\tau_0$ has a distinct color.)

Let $B_1$ and $B_2$ be any two hexagons separated by the same sequence of directions. *A priori*, $B_1$ and $B_2$ need not have the same color – but the folowing inductive argument shows that, in fact, they do:

We travel from $A_1$ to $B_1$ along some sequence of directions $(e_1, \ldots, e_s)$; the same sequence of directions will take us from $A_2$ to $B_2$. Now, starting from $A_1$ and $A_2$, and travelling along each direction in $(e_1, \ldots, e_s)$ simultaneously from each of the two hexagons, we pass through regions of the same color at each point (either because all the fundamental domains are colored the same, or because they have been identified in a routine way); hence, $B_1$ and $B_2$ are of the same color.

We claim that there exists some $a > 0$ such that any two hexagons separated by a sequence of $a$ 'S's (or equivalently $a$ '`N`'s) are of the same color. Pick any hexagon in $\tau$, and travel in the `S` direction. Among the first $t + 1$ hexagons reached during this journey, some two must have the same color – say, separated by a sequence of $a_0$ `S`s. From our work above, it follows that *any* two hexagons

separated by such a sequence are of the same color. So, we may set $a = a_0$. We can go even further, though, and choose $a > 0$ above to be minimal.

We now construct our desired fundamental domain as follows. Find $a$ as above. Pick any hexagon $H_{1,1}$ in the tiling of the plane, and take the $a$ hexagons $H_{1,1}, \ldots, H_{a,1}$ obtained by starting from $H_{1,1}$ and traveling in the S direction $a-1$ times. By the minimal definition of $a$, these have distinct colors. If there are already $t$ hexagons here, we have our fundamental domain.

Otherwise, travel from $H_{1,1}$ in the SE direction to reach another hexagon $H_{1,2}$, and travel in the S direction $a-1$ times to again yield $a$ hexagons $H_{1,2}, \ldots, H_{a,2}$ of distinct colors (by the minimal definition of $a$). (Note that by traveling from any $H_{r,1}$ in the SE direction, one can reach $H_{r,2}$.) Suppose, for sake of contradiction, that one of $H_{1,2}, \ldots, H_{a,2}$ were the same color as one of $H_{1,1}, \ldots, H_{a,1}$. We would then have that *each* of $H_{1,2}, \ldots, H_{a,2}$ is the same color as one of $H_{1,1}, \ldots, H_{a,1}$; and furthermore, that *all* hexagons in the tiling $\tau$ is the same color as one of $H_{1,1}, \ldots, H_{a,1}$. This contradicts our construction of $\tau$ from $\tau_0$. We now have found an $a \times 2$ cluster of hexagons, each of a different color. If there are already $t$ hexagons here, we have our fundamental domain.

Otherwise, travel from $H_{1,2}$ in the SE direction to reach another hexagon $H_{1,3}$, and define $H_{1,3}, \ldots, H_{n,3}$ in the natural way. These new $a$ hexagons have distinct colors; and as before, these colors must be distinct from those of $H_{1,1}, \ldots, H_{a,1}, H_{1,2}, \ldots, H_{a,2}$. We now have found an $a \times 3$ cluster of hexagons, each of a different color. If there already $t$ hexagons, we have our fundamental domain.

Otherwise, we can continue on, although because $t$ is finite, eventually we're bound to find our fundamental domain. Also, note that the N edges of the N-most hexagons of our fundamental domain our identified with the S edges of the S-most hexagons; similarly with the SE-most and NW-most edges. Indeed, the SE-most and NW-most edges are identified "naturally" with each other.

The next major step is to finding a short noncontractible path along the perimeter of the tiling.

It is sufficient to show that there exists a sequence $\mathcal{S} = (d_1, d_2, \ldots, d_k)$ of directions (along edges)

in $\{\texttt{e}, \texttt{se}, \texttt{sw}, \texttt{w}, \texttt{nw}, \texttt{ne}\}$ with the following properties:

(i) at most $n = \frac{1}{3}t$ of the $d_i$ equal `e` or `w`, at most $t$ of the $d_i$ equal `se` or `nw`, and at most $n$ of the $d_i$ equal `sw` or `ne`;

(ii) from any hexagon's northwest vertex, travelling according to $\mathcal{S}$ gives a closed, noncontractible path around the torus.

(Note that if we have two vertices in the tiling of the plane which correspond to the same points on the torus, then any continuous path between corresponds to a contractible closed path on the torus. With a little work, this fact can be used to ensure that the paths we find below are noncontractible.)

We select a $(3a) \times b$ "grid" of hexagons in the tiling which serve as a fundamental domain, where all four sides of our fundamental domain contain `nw-se` edges and the tom and bottom sides are identified naturally. Note that it suffices to prove the claim starting from the northwest corner $v_0$ of the top edge. Also note that $n = ab$.

If $b \geq 3$, then $(d_1, d_2, d_3, d_4, \ldots, d_{6a}) = (\texttt{sw}, \texttt{se}, \texttt{sw}, \texttt{se}, \ldots, \texttt{sw}, \texttt{se})$ suffices.

If $(a, b) = (1, 2)$, then $(d_1, d_2, d_3, d_4) = (\texttt{e}, \texttt{se}, \texttt{e}, \texttt{ne})$.

Because $t \geq 6$, we cannot have $(a, b) = (1, 1)$. Thus, we may assume that $a \geq 2$ and $b \leq 2$. We begin our journey by travelling from $v_0$ along $2b - 1$ edges, alternating between travelling `e` and `se` so that we travel `e` $b$ times and `se` $b - 1$ times. This brings us to a vertex $v_1$ on the left side of our fundamental domain.

If $v_1$ is the west vertex of one of the middle $a$ hexagons of our grid, then our initial $2b - 1$ movements `e`, `se`, ..., `e` are the "same" as between $2a + 1$ and $4a - 1$ movements `sw`, `se`, ..., `se`. From $v_1$, travel `se`; then repeat our initial $2b - 1$ movements. Our journey is then the "same" as moving between $2(2a + 1) + 1 = 4a + 3$ and $2(4a - 1) + 1 = 8a - 1$ edges `sw`, `se`, ..., `se`. In other words, we are now at some vertex $v_2$ which is the west vertex of either (a) one of the top $a$ hexagons of the first column; or (b) one of the bottom $a$ hexagons of the first column.

In either case, we have travelled e at most $2b$ times and se at most $2b-1$ times. And we are now either (a) on the west vertex of one of the top $a$ hexagons of the first column, or (b) on the west vertex of one of the bottom $a$ hexagons of the first column.

In case (a), we may alternate between travelling ne and nw to reach $v_0$, travelling ne at most $a$ times and nw at most $a-1$ times. Altogether, then, we have travelled: e at most $2b$ times, so total is $2b \leq ab$; se at most $2b-1$ times and nw at most $a-1$ times, so total is $a+2b-2 = ab-(a-2)(b-1) \leq ab$; ne at most $a$ times so total is $a \leq ab$.

Hence, condition (ii) is satisfied.

In case (b), we may alternate between travelling se and sw to reach $v_0$, travelling se at most $a$ times and sw at most $a-1$ times. Altogether, then, we have travelled: e $\leq 2b$ times, so total is $2b \leq ab$; se $\leq a+2b-1$ times, so total is $a+2b-1 = ab-(a-2)(b-1)+1 \leq ab+1$; sw $\leq a-1$ times, so total is $a-1 \leq ab$.

Hence, condition (ii) is satisfied if $a > 2$, because in this case the second inequality above is strict.

If $a = 2$, then it seems that we might have an incredible stroke of bad luck so that all our approximations above are sharp. Actually, though, this doesn't happen: one can verify that with a $6 \times 1$ or $6 \times 2$ grid, we can still find a path of the desired form. (To do so in the $6 \times 2$, we need to use the barbell property.)

We now make the final points to show that $\tau_0$ has perimeter greater than 3.

For each of our $t$ hexagons, start at the northwest vertex of the hexagon and travel along $(d_1, d_2, \ldots, d_k)$ as in the lemma of the previous section. Each of these $t$ overlapping paths uses at most $n = t/3$ edges parallel to the e (resp. se or sw) direction, implying that they use a total of $t^2/3$ such edges. Furthermore, a symmetry argument implies that all of the $t$ edges parallel to the e (resp. se or sw) direction are used the same number of times in these $t$ paths. Therefore, each edge is used at most at most $(t^2/3)/t = t/3$ times in these overlapping paths.

Thus, the total perimeter $P'$ of the $t$ overlapping paths is at most $t/3$ times the perimeter $P$ of $\tau_0$.

Furthermore, each of the $t$ overlapping paths has perimeter greater than 1, implying that altogether their total perimeter $P'$ is greater than $t$.

It follows that

$$t < P' \leq (t/3)P,$$

or $P > 3$. QEF

**Lemma 6.11.** A hexagon tiling $\Upsilon$ with 6 components has perimeter strictly greater than 3.

**Definition 6.1.** Let a *barbell* be a pair of hexagons related as in Figure 6.12. Then the two hexagons each adjacent to both hexagons of the pair must be of different regions (B and C in Figure 6.12), and the two hexagons of the barbell must be of the same region (A in Figure 6.12).

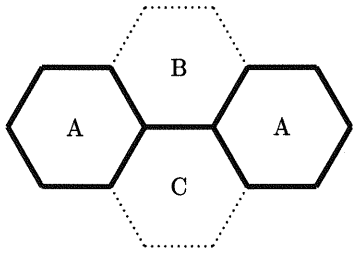

Figure 6.12: Regularity satisfying hexagon tilings exhibit the barbell-lift property.

**Definition 6.2.** Let a *web* $W$ be a set of hexagons $\{x_1, x_2, ..., x_n\}$ in the lift of a tiling such that for any hexagon $x_i \in W$, another hexagon $y$ is also in $W$ if $x_i$ and $y$ are contained in the same barbell.

Then every hexagon in a web must be of the same region. Furthermore, a web contains exactly one third of the hexagons in the tiling, so all components of a region are contained in a single web.

*Proof.* By the perimeter bound, a double bubble whose set of boundary curves contains three non-contractible non-geodesic circles as disjoint subsets is not perimeter-minimizing. We show that $\Upsilon$ must contain three such circles by considering the lift of $\Upsilon$ to the plane.

Let the three regions of the tiling be labelled $A$, $B$, and $C$. Note that in the lift, there are exactly two unique hexagonal components of each region; let these components be labelled $A_1$, $A_2$, $B_1$, $B_2$, $C_1$, and $C_2$.

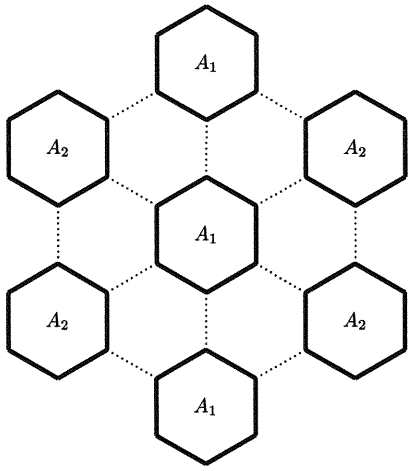

Figure 6.13: Structure of the lift of a six-hexagon tiling.

Now consider a seven-hexagon segment of a web as in Figure 6.13. Let the center hexagon be $A_1$. Then the other six hexagons must all be of region $A$, by the definition of a web. Further, at least one of the other six hexagons must also be $A_1$, since if all of them were $A_2$ then we would have the relation that every hexagon directly above or below $A_2$ in the web was also $A_2$, which would imply that the center hexagon was $A_2$, a contradiction. Let the hexagon immediately below the center hexagon be $A_1$. This immediately implies that the hexagon above the center hexagon is also $A_1$, again by identification. Now if any of the remaining four hexagons is $A_1$, then all of the hexagons in the segment, and therefore all of the hexagons in the web, must also be $A_1$. Thus, the remaining four hexagons must all be $A_2$. Now, considering the web as a whole we see that it consists of alternating vertical stripes of $A_1$ and $A_2$ hexagons. Now consider the hexagon adjacent and to the left of the center hexagon in the original web segment. Let this hexagon be the unique hexagon $B_1$. Then every $A_1$ hexagon has a $B_1$ hexagon adjacent and to its left, and we see that in the $B$ web

we also have alternating vertical stripes of $B_1$ and $B_2$ hexagons. The same pattern holds for the $C$ web. Thus, there is a single fundamental pattern in the arrangement of the six unique hexagons, up to rotation and relabelling. See Figure 6.13.

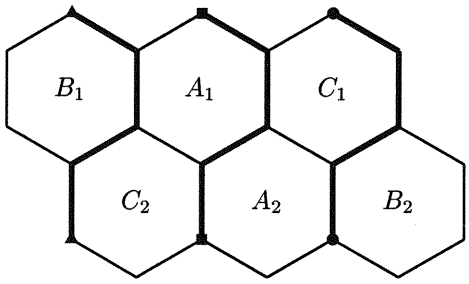

Figure 6.14: A fundamental domain for a six hexagon tiling has perimeter greater than three, since we can exhibit three non-trivial closed curves.

Now the set of six hexagons in Figure 6.14, with boundary curves identified as shown, has precisely the same structure and contains precisely the same perimeter as a six-hexagon tiling of a parallelogram torus. The three paths highlighted in Figure 6.14 are three disjoint non-contractible non-geodesic circles, since for each path the endpoints are in fact the same (identified) point. QEF

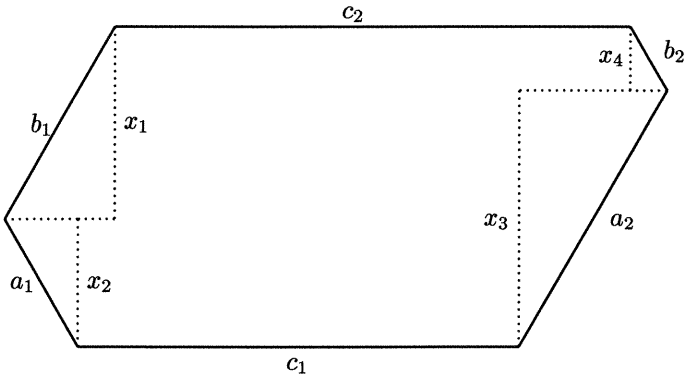

Figure 6.15: In a hexagon with regular angles, a simple geometric construction shows that opposite adjacent side pairs have perimeters which sum to the same total.

**Lemma 6.12.** In a hexagon that satisfies regularity, the sum of the lengths of two sides that are adjacent is the same as the sum of the lengths of the opposite pair of adjacent sides.

*Proof.* Let two adjacent sides of a regular hexagon be labelled $a_1$ and $b_1$, the opposite pair of adjacent sides be labelled $a_2$ and $b_2$, and the remaining two sides be labelled $c_1$ and $c_2$, as in Figure 6.15. Also, let the vertex between $a_1$ and $b_1$ be $V_1$ and the vertex between $a_2$ and $b_2$ be $V_2$. Then since $c_1$ and $c_2$ are parallel, the sum of the perpendicular distance from $V_1$ to each of $c_1$ and $c_2$ is the same as the sum of the perpendicular distance from $V_2$ to each of those sides; labelling these distances as in Figure 6.15, we get $x_1 + x_2 = x_3 + x_4$. Now, by the Law of Sines we have $a_1 = \frac{x_1}{sin(\frac{\pi}{3})}$, $b_1 = \frac{x_2}{sin(\frac{\pi}{3})}$, $a_2 = \frac{x_4}{sin(\frac{\pi}{3})}$, and $b_2 = \frac{x_3}{sin(\frac{\pi}{3})}$. Combining these equations, we get $a_1 + b_1 = a_2 + b_2$, as desired. QEF

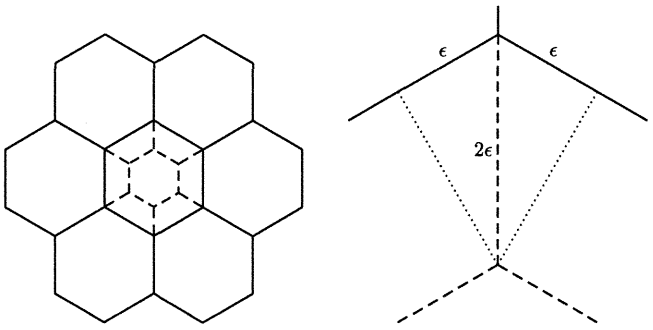

Figure 6.16: Shrinking or expanding components of a tiling of hexagons generates double bubbles enclosing different areas, but does not change perimeter.

**Lemma 6.13.** A 3-component straight-edge hexagon tiling enclosing arbitrary areas has the same perimeter as a 3-component straight-edge hexagon tiling of equal areas.

*Proof.* First, note that "shrinking" or "expanding" a single hexagon in a straight-edged hexagon tiling (as in Figure 6.16 is a smooth variation through equilibrium double bubbles and hence maintains perimeter.

Now consider the three unique hexagons in a 3-component straight-edge hexagon tiling, with boundary curves identified as in Figure 6.17. Let the nine unique sides, in three groups each of three sides parallel to one another, be labelled $a_1$, $a_2$, $a_3$, $b_1$, $b_2$, $b_3$, $c_1$, $c_2$, and $c_3$, such that $a_1 \geq a_2 \geq a_3$, $b_1 \geq b_2 \geq b_3$, and $c_1 \geq c_2 \geq c_3$. Then if $a_1 = a_2 = a_3$, $b_1 = b_2 = b_3$, and $c_1 = c_2 = c_3$, the three hexagons are congruent and therefore have equal area. (In fact, any one of these equality equations implies the other two, by Lemma 6.12). We show that by shrinking or expanding hexagons we can transform any straight-edged hexagon tiling into one with congruent hexagons.

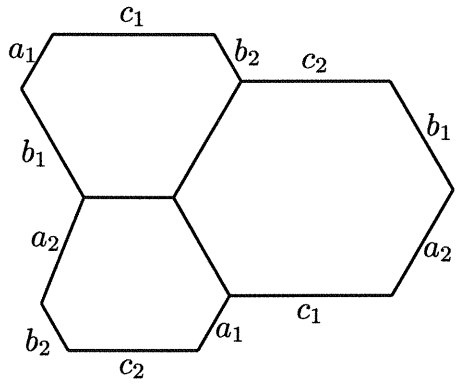

Figure 6.17: A generic fundamental region of a three-hexagon tiling looks something like this.

We start by showing that we can always label the nine sides in such a way that the hexagon $H_1$ with sides labelled $a_1$ and $a_2$ also has sides $b_1$, $b_2$, $c_1$, and $c_2$. Let the remaining sides of $H_1$ besides $a_1$ and $a_2$ be $b_a$, $b_b$, $c_a$, and $c_b$, as in Figure 6.17. Since $a_1 \geq a_2$, by Lemma 6.12 we know that $b_a \geq b_b$ and $c_a \geq c_b$. Similarly, since $a_1 \geq a_3$, we have $b_a \geq b_c$ and $c_a \geq c_c$, and since $a_2 \geq a_3$, we have $b_b \geq b_c$ and $c_b \geq c_c$. Thus we can always set $b_a = b_1$, $b_b = b_2$, $c_a = c_1$, $c_b = c_2$, and $c_c = c_3$ so that $H_1$ has sides with subscripts 1 and 2, while $H_2$ has sides all of subscript 1 or 3, and a hexagon $H_3$ has sides all of subscript 2 or 3.

Now consider a straight-edged three-hexagon tiling with hexagons of unequal area and side labels as described above. Then at least one of the inequalities in $a_1 \geq a_2 \geq a_3$ must be strict, or the tiling would be equal-area.

Suppose $a_1 > a_2$. Then know from Lemma 6.12 that $b_1 > b_2$ and $c_1 > c_2$. Now let us "expand" $H_3$ by lengthening $a_2$, $a_3$, $b_2$, $b_3$, $c_2$ and $c_3$ while shortening $a_1$, $b_1$, and $c_1$, until $a_1 = a_2$. We know we can do this smoothly, since $a_1$ is bounded below by $a_2$. Note also that by Lemma 6.12, $a_1 = a_2$ implies $b_1 = b_2$ and $c_1 = c_2$, so during the transformation we also have $b_1$ bounded from below by $b_2$, and $c_1$ bounded below by $c_2$. Thus none of the sides that we are shortening vanishes to zero length.

Now either $a_1 = a_2 = a_3$ and we are done, or $a_1 = a_2$ and $a_2 > a_3$. If the latter, then let us "shrink" $H_1$ by shortening $a_1$, $a_2$, $b_1$, $b_2$, $c_1$, and $c_2$ while lengthening $a_3, b_3$, and $c_3$, until $a_2 = a_3$. Again, we know we can do this smoothly, since $a_1$ and $a_2$ are bounded from below by $a_3$. As before, $a_2 = a_3$ implies $b_2 = b_3$ and $c_2 = c_3$, so $b_1, b_2, c_1$, and $c_2$ are all bounded from below as well.

Thus, by expanding $H_3$ and/or shrinking $H_1$ as necessary, we can continuously deform any straight-edged hexagon tiling into one with congruent hexagons, and thus equal areas. QEF

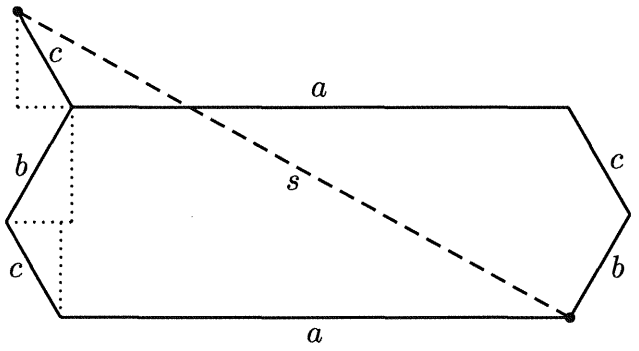

Figure 6.18: A closed geodesic in a three-hexagon tiling. It is a simple geometric argument to show that $a + b + c > s$, except in the case of the hexagonal torus, which implies that the hexagonal tiling in all other cases loses to the double band solution.

**Lemma 6.14.** A 3-component straight-edge hexagon tiling with congruent hexagons has perimeter strictly greater than 3 on all tori except the hexagonal torus.

*Proof.* A 3-hexagon tiling with congruent hexagons has three unique side lengths, $a \geq b \geq c$, and perimeter $P = 3(a + b + c)$. We show that unless $a = b = c$, $a + b + c$ is always greater than the length of a closed geodesic, and therefore the perimeter P is always greater than 3.

Consider some hexagon in such a tiling, and let $V_1$ be a vertex between sides of length $a$ and $b$. Then the line connecting the diametrically opposed vertex $V_2$ (also between sides of length $a$ and $b$) with the copy of $V_2$ that is connected to $V_1$ by a single side of length $c$, is a closed geodesic. See Figure 6.18.

Let $s$ be the length of that geodesic. Then by the Pythagorean Theorem we have $s^2 = (\frac{\sqrt{3}}{2}c + \frac{\sqrt{3}}{2}b + \frac{\sqrt{3}}{2}c)^2 + (a + \frac{c}{2} - \frac{b}{2} + \frac{c}{2})^2$, which reduces to

$$\begin{aligned} s^2 &= a^2 + b^2 + 4c^2 + 2ac + 2bc - ab \\ &= (a^2 + b^2 + c^2 + 2ac + 2bc + 2ab) - 2ab + 3c^2 - ab \\ &= (a + b + c)^2 + 3c^2 - 3ab. \end{aligned}$$

Now suppose at least one of the inequalities in $a \geq b \geq c$ is strict. Then $c^2 < ab$, so $3c^2 - 3ab < 0$ and $(a + b + c)^2 > s^2$. Thus $P = 3(a + b + c) > 3s$, so the perimeter of the tiling is strictly greater than three unless $a = b = c$. Note from Figure 6.19 that the latter condition can only be satisfied on the hexagon torus, and that in this case the geodesic we constructed above is the shortest closed geodesic so the perimeter of the tiling is precisely 3. QEF

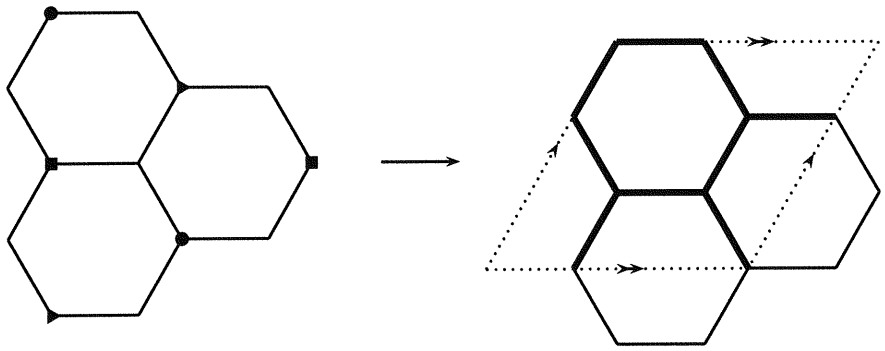

Figure 6.19: A three-hexagon tiling of congruent hexagons fits on the hexagonal torus, and is in fact a minimizer.

**Proposition 6.13.** The only hexagon tiling that is perimeter-minimizing is the 3-component straight-edge hexagon tiling on the hexagonal torus.

*Proof.* By Lemma 6.9, the number of components in a minimizing hexagon tiling must be a multiple of 3. By Lemma 6.10, a hexagon tiling with 9 or more components is not perimeter-minimizing. By Lemma 6.11, a hexagonal tiling with 6 components has perimeter strictly greater than 3, so by the perimeter bound it is not perimeter-minimizing. Thus, a perimeter-minimizing hexagon tiling must have exactly 3 components. By Proposition 6.12, a perimeter-minimizing hexagon tiling must have straight edges. By Proposition s 6.13 and 6.14, a 3-component straight-line hexagon tiling has perimeter strictly greater than 3 on all tori except the hexagonal torus, so by the perimeter bound the only hexagon tiling that can be perimeter-minimizing is the 3-component tiling on the hexagonal torus.

QEF

## 6.6 Formulas for Perimeter and Area

This section gives formulae for area and perimeter of the three potential minimizers from section 6.5: the standard double bubble $\Theta$ (Proposition 6.14), the two-component symmetric chain $\Omega$ (Propositions 6.15, 6.16), and the band-lens $\Phi$ (Proposition 6.18). We use these formulae to obtain the phase portrait of Figure 6.2. Propositions **??** and 6.19 show that the two-component symmetric chain and the band-lens are unique for prescribed areas.

### 6.6.1 Formulas for the Standard Double Bubble

We begin by stating a few simple geometric formulae that describe circular arcs meeting chords.

*Remark 6.4.* Given a circular arc $\lambda$ and a chord of length $C$ meeting the arc at (interior) angles $\theta$, the area between the arc and the chord, the length of the arc, and the radius of the circle are given

by:

$$A(\theta, C) = \frac{C^2(\theta - \sin\theta\cos\theta)}{4\sin^2\theta} \tag{6.1}$$

$$L(\theta, C) = \frac{C(\theta)}{\sin\theta} \tag{6.2}$$

$$R(\theta, C) = \frac{C}{2\sin\theta} \tag{6.3}$$

Here area means the area between an arc and chord.

Formulae for perimeter and area of the standard double bubble as derived by Foisy [24, Section 2] are given in the following proposition.

**Proposition 6.14.** The area and perimeter formulae of a standard double bubble in terms of the separating chord length $C$ and the angle $\theta$ at which it meets the interior arc are (smaller region $R_1$)

$$A_{R_1}(\theta, C) = A(\frac{2\pi}{3} - \theta, C) + A(\theta, C)$$

$$A_{R_2}(\theta, C) = A(\frac{2\pi}{3} + \theta, C) - A(\theta, C)$$

$$P(\theta, C) = L(\frac{2\pi}{3} + \theta, C) + L(\frac{2\pi}{3} - \theta, C) + L(\theta, C)$$

*Proof.* These formulae follow directly from Equations 6.1-6.3. QEF

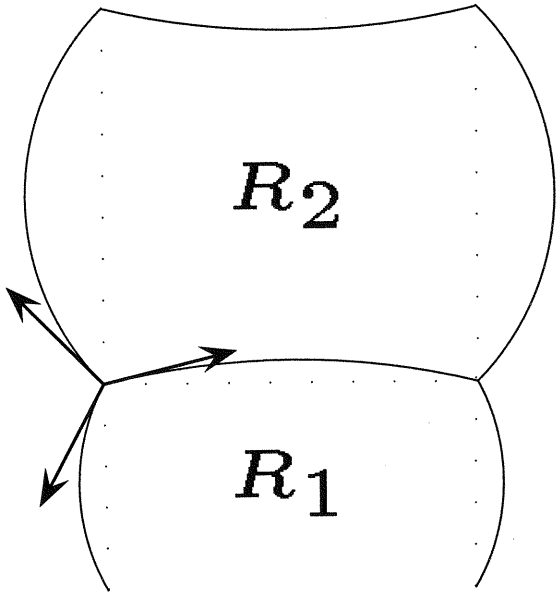

Figure 6.20: Important angles and lengths in a symmetric two component swath.

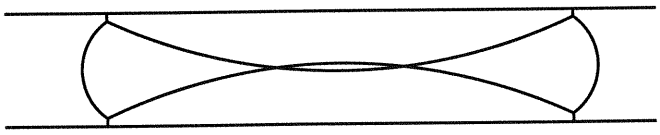

Figure 6.21: Arcs curve the right direction but intersect.

### 6.6.2 Formulas for the Standard 2-Component Symmetric Chain

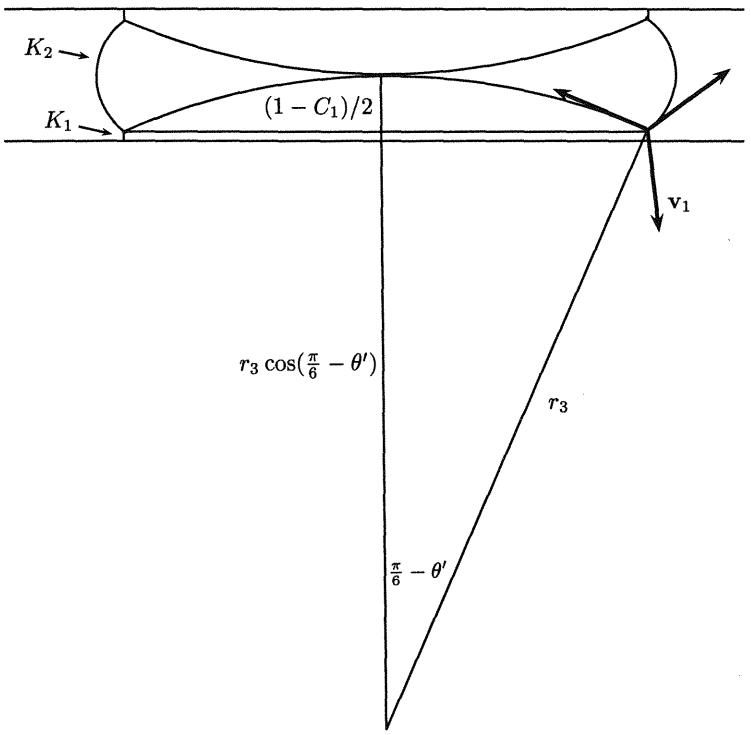

Figure 6.22: Conditions for tangency give the appropriate lower limit of the parameter $\theta_1$.

Representing vertices by rectangles in a 2-component symmetric chain, gives a natural parameterization in terms of an angle $\theta_1$ and a chord length $C_1$ determined by the boundary of the highest pressure region, $R_1$, with the exterior (Figure 6.20). We label this curve $\lambda_1$. Let $\theta_2$ and $C_2$ be the corresponding parameters for each arc $\lambda_2$ between the exterior and $R_2$. Similarly, $\theta_3$ and $C_3$ describe arcs $\lambda_3$ between $R_1$ and $R_2$.

Given $\theta_1$ and $C_1$, we can determine $\kappa_1$. The $\lambda_i$'s meet at 120°, so we get that $\theta_2 = \frac{\pi}{3} - \theta_1$ and $\theta_3 = \frac{\pi}{6} - \theta_1$. Since $C_1 + C_2 = 1$, we recover $C_3$ from the radius formula above using the fact that curvatures add to zero at each vertex. In sum, we have:

$$C_2 = 1 - C_1;$$

$$\kappa_3 = \kappa_1 - \kappa_2;$$

$$\frac{1}{\kappa_1} = \frac{C_1}{2\sin\theta_1};$$

$$\frac{1}{\kappa_2} = \frac{C_2}{2\sin(\frac{\pi}{3} - \theta_1)};$$

$$\frac{1}{\kappa_3} = \frac{C_3}{2\sin(\frac{\pi}{6} - \theta_1)}.$$

In terms of $C_1$ and $\theta_1$, the formula for $C_3$ becomes

$$C_3 = \frac{C_1(1 - C_1)\sin(\frac{\pi}{6} - \theta_1)}{(1 - C_1)\sin\theta_1 - C_1\sin(\frac{\pi}{3} - \theta_1)}.$$

Now we must specify a range of values for $\theta_1$ and $C_1$ where the swath makes sense, i.e. we find a parameter space where swaths do not violate regularity.

By symmetry, we can restrict $C_1$ to the open interval $(0, \frac{1}{2})$ (We exclude the endpoints to ensure uniqueness, and deal with these cases separately.) If we consider a frame of 3 vectors $v_1, v_2, v_3$ meeting at 120° we can model the set of tangent vectors to each arc at a given vertex (see Figure 6.21). In particular, we can place this frame at the intersection of the $\lambda_i$'s and consider the structural change of a bubble under a small rotation of the frame. In the case of $C_1 = \frac{1}{2}$, $v_3$ must coincide with $C_3$ otherwise $\lambda_3$ will bow into the region of higher pressure. For instance, rotating the frame slightly counterclockwise makes $\kappa_2 > \kappa_1$ which implies $R_2$ has higher pressure with respect to the exterior. Since $v_3$ points into $R_2$, this construction cannot work. For an arbitrary $C_1$ (less than $\frac{1}{2}$), we rotate the frame until $\kappa_1 = \kappa_2$, this particular construction cannot work since $v_3$ must point horizontal if the regions have equal pressure. Rotating the frame slightly counterclockwise presents the same problem as before. If we rotate clockwise, we may initially produce a chain which intersects itself (see Figure 6.21)). At a certain value $\theta'$ of $\theta_1$ the $\lambda_3's$ are tangent and beyond that, until $\theta_1 = \frac{\pi}{6}$,

the construction is regular. (Unless $C_1 = \frac{1}{2}$ the angle $\theta_1 = \frac{\pi}{6}$ is not valid. Again, we treat this case separately.)

We see from figure 6.20) that $\theta'$ satisfies

$$r_3 \cos(\frac{\pi}{6} - \theta') + \frac{1 - C_1}{2} = r_3$$

Upon further simplification, this condition reduces to

$$C_1 = \sin\theta'$$

Thus, $\theta_1$ must lie in $(\sin^{-1}(C_1), \frac{\pi}{6})$. We can now write down formulae for the area and perimeter of chains.

**Proposition 6.15.** Using the parameterization of Section 6.6.2, the area and perimeter formulae for symmetric chains with components of unequal pressure are

$$P(\theta_1, C_1) = 2L(\theta_1, C_1) + 2L(\frac{\pi}{3} - \theta_1, C_2) + 2L(\frac{\pi}{6} - \theta_1, C_3)$$

$$A_{R_1}(\theta_1, C_1) = 2A(\theta_1, C_1) + 2A(\frac{\pi}{6} - \theta_1, C_3) + C_1C_3$$

$$A_{R_2}(\theta_1, C_1) = 2A(\frac{\pi}{3} - \theta_1, C_2) - 2A(\frac{\pi}{6} - \theta_1, C_3) + C_2C_3$$

where $C_2$ and $C_3$ are given by

$$C_2 = 1 - C_1$$

$$C_3 = \frac{C_1(1 - C_1)\sin(\frac{\pi}{6} - \theta_1)}{(1 - C_1)\sin\theta_1 - C_1\sin(\frac{\pi}{3} - \theta_1)}.$$

*Proof.* These formulae follow directly from the parameterization and Equations 6.1-6.2. QEF

Now we must treat the case where $C_1 = \frac{1}{2}$. We showed above that $\theta_1 = \frac{\pi}{6}$ at this point, otherwise the construction is irregular. However, this does not determine a unique value for $C_3$, in fact, it can take on any value greater than zero. Since all other arc lengths and angles in the chain are fixed, we have a simple formula relating volume and perimeter of such chains.

**Proposition 6.16.** In symmetric chains comprised of equal pressure components, perimeter as a function of the area of one region is given by

$$P(A_{R_1}) = 4A + \frac{2\pi + 3\sqrt{3}}{6}$$

where $A_{R_1} > 2A(\frac{\pi}{6}, \frac{1}{2}) = \frac{2\pi - 3\sqrt{3}}{24}$

*Proof.* By Equations 6.1-6.2, we know the perimeter and area in terms of $C_3$

$$P = 4L(\frac{\pi}{6}, \frac{1}{2}) + 2C_3 = \frac{2\pi}{3} + 2C_3$$

$$A_{R_1} = A_{R_2} = 2A(\frac{\pi}{6}, \frac{1}{2}) + \frac{C_3}{2} = \frac{2\pi - 3\sqrt{3}}{24} + \frac{C_3}{2}$$

This allows us to get perimeter as a function of area. Combining equations yields

$$P = 4A_{R_1} + \frac{2\pi + 3\sqrt{3}}{6}$$

For, $A_{R_1} > 2A(\frac{\pi}{6}, \frac{1}{2}) = \frac{2\pi - 3\sqrt{3}}{24}$, the chain is regular QEF

**Conjecture 6.3.** Given prescribed areas $a_1$ and $a_2$, and up to isometries of the torus, there is a unique standard two-component symmetric chain with homology $(1, 0)$ enclosing these areas.

Note that even if this conjecture fails, all we really need is the weaker result that the chain is unique *when it is minimizing*. This is probably not at all hard to show.

**Proposition 6.17.** For a given set of area pairs, and based on the parameterization described in this subsection, if the perimeter of an immersed symmetric is less than or equal to the perimeter of the embedded minimizer for those areas, then it is itself embedded.

*Proof.* We must consider the case when the symmetric chain overlaps itself around the torus. Clearly, $C_3$ must be less than .5, or else the double bubble would have perimeter greater than three. $C_3$ is perpendicular to the shortest side of the torus, so $C_3 < L \cdot \sin(\theta)$, where $\theta$ is the smallest interior angle of the torus, since otherwise two vertices which fall on a geodesic, $g_1$, in the short direction,

would wrap around past the other two vertices (which also lie on a geodesic, $g_2$) and there would be no exterior. This case falls outside of our calculation and thus we do not need to consider it.

Thus, there exists a distance $\epsilon = L \cdot \sin(\theta) - C_3 > 1 \cdot \sin(\frac{\pi}{3}) - 1/2 > .365$ that separates $g_1$ and $g_2$. But somewhere in the parallelogram that lies between $g_1$ and $g_2$, the double bubble intersects itself. Now there are three cases. Case 1 is when $R_1$ or $R_2$ intersects one of the vertices of the chain. Case 2 is when $R_1$ intersects $R_2$. Case 3 is when $R_1$ or $R_2$ intersects itself.

Case 1: Assume that $R_1$ intersects one of the vertices of the chain. Thus, given $\lambda_1$ and the height, $h_1$ that it makes with its chord, then $h_1 > \epsilon$.

Now, we'd like to calculate the length of $\lambda_1$,

$$L(\lambda_1) = \frac{C_1 \cdot \theta_1}{\sin(\theta_1)}.$$

But

$$\tan(\theta_1/2) = \frac{h_1}{(C_1/2)}.$$

So

$$C_1 = \frac{2 \cdot h_1}{\tan(\theta_1/2)} > .73/tan(\theta_1/2).$$

Thus,

$$L(\lambda_1) > \frac{2 \cdot \epsilon \cdot \theta_1}{\tan(\theta_1/2) \cdot \sin(\theta_1)}.$$

We put

$$f(x) = \frac{x}{\tan(x/2)\sin(x)} = \frac{x \cdot \cos(x) + x}{\sin(x)^2}.$$

Then

$$f'(x) = \frac{-(x \cdot (\cos(x))^2 - (\sin(x) - 2 \cdot x) \cdot \cos(x) - \sin(x) + x)}{\sin(x)^3}.$$

But since $x > sin(x)$ for $x > 0$, on the interval $[0, \pi/3]$, $f'(x) < 0$ and thus $f$ is decreasing. Thus,

$$L(\lambda_1) > \frac{.73 \cdot \pi/3}{\tan(\pi/6) \cdot \sin(\pi/3)} > 1.528,$$

and so $P > 2 \cdot 1.528 > 3$.

Case 2: Assume that $R_1$ intersects $R_2$ but neither intersects one of the vertices of the chain. Thus, given $\lambda_1$ and $\lambda_2$, and the height, $h_1$ and $h_2$ that each makes with its respective chord, either $h_1 + h_2 > \epsilon$.

Now, we would like to calculate the sum of the lengths of $\lambda_1$ and $\lambda_2$,

$$L(\lambda_1) + L(\lambda_2) = \frac{C_1 \cdot \theta_1}{\sin(\theta_1)} + \frac{C_2 \cdot \theta_2}{\sin(\theta_2)}$$

. But

$$\tan(\theta_i/2) = \frac{h_i}{(C_i/2)}.$$

So

$$C_i = \frac{2 \cdot h_i}{\tan(\theta_i/2)}.$$

Thus,

$$L(\lambda_1) + L(\lambda_2) = \frac{2 \cdot h_1 \cdot \theta_1}{\tan(\theta_1/2) \cdot \sin(\theta_1)} + \frac{2 \cdot h_2 \cdot \theta_2}{\tan(\theta_2/2) \cdot \sin(\theta_2)}.$$

But, from above

$$f(x) = \frac{x}{\tan(x/2)\sin(x)} = \frac{x \cdot \cos(x) + x}{\sin(x)^2}$$

is decreasing. So if we assume, without loss of generality that $\theta_1 \geq \theta_2$, then

$$L(\lambda_1) + L(\lambda_2) \geq \frac{2 \cdot h_1 \cdot \theta_1}{\tan(\theta_1/2) \cdot \sin(\theta_1)} + \frac{2 \cdot h_2 \cdot \theta_1}{\tan(\theta_1/2) \cdot \sin(\theta_1)} > \frac{2 \cdot \epsilon \cdot \theta_1}{\tan(\theta_1/2) \cdot \sin(\theta_1)} > 1.528$$

for all $\theta$ in the interval $[0, \pi/3]$, as above. So $P > 2 \cdot 1.528 > 3$.

Case 3: Now assume that $R_1$ intersects itself. They will clearly intersect in a lens. We can remove the lens, and get the area back with less perimeter in the exterior. (This is where I wanted to have the isoperimetric inequality for free boundary closed surfaces - I employ a different method that needs tuning.) To see this, align the lens perpendicular to the axis of symmetry of the chain and center it over the $\epsilon$-rectangle and where the exterior is widest. If the exterior is not wider at this point than the lens, separate the two circular arcs of the lens and slide them apart until the intersection of these arcs with the exterior encloses the same area that the lens had, and with less perimeter. If this

component of the exterior does not have enough area, take the whole component and repeat with a different component. If there is not enough area in the whole region, then the immersed double bubble lies outside our calculations. We must still consider the case where the exterior is too wide. If the lens fits, we are done. If not, then... I can't explain this without a picture. I will get on that for next time. QEF

This completes the description of symmetric chains. Note that when computing perimeter later, we restrict our parameter space even more by requiring $C_3 < \frac{1}{2}$, since the polygonal arc length of chains not satisfying this inequality is already greater than 3.

### 6.6.3 Formulae for the Band-Lens

The family of Band-Lens bubbles can be parameterized nicely in terms of two parameters, $r$, the radius of curvature ($\frac{1}{curvature}$) of the lens, and $d$, the width of the band. Of course, the lens can only be as tall as the cylinder, so $r$ can be at most $\frac{1}{2\sin\frac{\pi}{3}} = \frac{1}{\sqrt{3}}$. For a given $r$, the width of the band must be at least half the width of the lens. Thus $d$ is at least $\frac{r}{2}$. From this we can compute the area and perimeter of a Band-Lens.

**Proposition 6.18.** The area and perimeter formulae for a band-lens bubble in terms of $r$ and $d$ ($r < \frac{1}{\sqrt{3}}, d > \frac{r}{2}$) are

$$A_{Lens}(r) = 2r^2(\frac{\pi}{3} - \frac{\sqrt{3}}{4})$$

$$A_{Band}(r,d) = d - r^2(\frac{\pi}{3} - \frac{\sqrt{3}}{4})$$

$$P(r,d) = (\frac{4\pi}{3} - \sqrt{3})r + 2$$

*Proof.* Using Equations 6.1-6.2 we can compute the area of both components. The chord length $C$ of the lens is $2r\sin\frac{\pi}{3} = \sqrt{3}r$. This gives us

$$A_{Lens}(r) = 2A(\frac{\pi}{3}, \sqrt{3}r) = 2r^2(\frac{\pi}{3} - \frac{\sqrt{3}}{4})$$

$$A_{Band}(r,d) = d - \frac{1}{2}A_{Lens}(r) = d - r^2(\frac{\pi}{3} - \frac{\sqrt{3}}{4})$$

The perimeter is given by

$$P(r,d) = 2L(\frac{\pi}{3}, \sqrt{3}r) + (2 - \sqrt{3}r) = (\frac{4\pi}{3} - \sqrt{3})r + 2$$

QEF

**Proposition 6.19.** Given prescribed areas $a_1$ and $a_2$, there exists a unique (up to isometry of the torus) minimal band-lens.

*Proof.* The lens is uniquely determined by the length, $C$, of the chord separating its vertices, and the interior angle $\theta$ between the two boundary arcs. By regularity $\theta$ is fixed. Moreover, the area of the lens is strictly increasing in $C$. Thus, given the smallest area $A_1$ of the three regions of the double bubble, there is a unique lens enclosing that area. The chord of the lens must lie parallel to the short side of the torus and thus the lens is positioned uniquely up to translation. Further, the vertices are connected by a uniquely determined line segment also parallel to the short direction of the torus and there exists a unique geodesic in the short direction which will enclose the proper area. QEF

**Proposition 6.20.** For a given set of area pairs, and based on the parameterization described in this subsection, if the perimeter of an immersed band-lens is less than or equal to the perimeter of the embedded minimizer for those areas, then it is itself embedded.

*Proof.* The first case we consider is the case in which the band with smaller area is too narrow, so that the shortest closed geodesic which is a component of its boundary intersects the boundary of the lens. But we can create a new, embedded, double bubble by eliminating the section of the geodesic which intersects the lens and sliding the rest of the geodesic inward to compensate for area. But this double bubble has perimeter less than the band lens, and further, contradicts regularity. So for such "difficult" area pairs, the band-lens is not a minimizer.

The second case to be considered is the case in which the lens does not fit along the short direction of the torus. In this case, the double bubble clearly has perimeter greater than three, and by Proposition 6.3, it cannot be a minimizer. Thus, if the immersed band-lens would minimize perimeter, then it must be embedded. QEF

## 6.7 Perimeter Minimizing Double Bubbles on the Flat 2-Torus and the Infinite Cylinder

**Main Theorem 1.** Each perimeter minimizing double bubble on a flat 2-torus is one of the following six types, depending on the areas to be enclosed:

i) the standard double bubble, $\Theta$,

ii) the band-lens, $\Phi$,

iii) the double band, $\Xi$,

iv) a symmetric two-component chain $\Omega$,

v) the hexagon tiling, $H$, on the hexagonal torus, or

vi) an octagon-square tiling, $X$.

Conjecture 1 says that the octagon-square tiling is never perimeter-minimizing.

*Proof.* Proposition 6.6 shows that a minimizer must be either a a contractible double bubble, a tiling, a swath, a band adjacent to a set of components whose union is contractible, or the double band (after perhaps relabelling the two regions and the exterior).

First we consider all minimizers that do not fall in the class of tilings.

By Proposition 6.1, the only potential contractible minimizer is the standard double bubble $\Theta$. By Proposition 6.10, the only potential swath minimizer is the symmetric two-component chain $\Omega$. By Proposition 6.11, the only potential minimizer among bands adjacent to a set of components whose union is contractible is the band-lens $\Phi$.

We focus here on potential minimizers that are tilings. Propositions 6.12 and 6.13 tell us that such a tiling must be either the special hexagon tiling $H$ or an octagon-square tiling. QEF

**Lemma 6.5.** On the flat 2-torus, there exist area pairs for which the band-lens is perimeter minimizing, and separately for which the standard double bubble is perimeter minimizing.

*Proof.* Consider regions $R_1$ and $R_2$ with area $A_1$ and $A_2$ in a perimeter minimizing double bubble. By [21] , the perimeter minimizing single bubble for area $A_1$ is either a single band, a circle, or the complement of a circle, depending on the area $A_1$. Thus, in the limit through minimizing double bubbles as $A_2$ goes to zero, we must get back the single band, circle, or complement of a circle enclosing $R_1$. This is only possible if for very small $A_2$, the minimizing double bubble is the band-lens or the standard double bubble which will in the limit be the single band or the circle or complement of a circle, respectively. QEF

**Corollary 6.1.** Each perimeter minimizing double bubble on a torus with unit shortest side length and longest side of length greater than $\sqrt{3}$ is of one of the following four types of Figure 6.1, depending on the areas to be enclosed:

i) the standard double bubble $\Theta$,

ii) the band-lens $\Phi$,

iii) the symmetric two-component chain $\Omega$, or

iv) the double band $\Xi$ formed by three geodesic circles.

*Proof.* By Proposition 6.4, no tiling can occur on a torus with unit shortest side length and longest side length greater than $\sqrt{3}$. Thus, by the Main Theorem, each perimeter minimizing double bubble must be of one of the above types.

QEF

**Corollary 6.2.** Each perimeter minimizing double bubble on the infinite cylinder of unit circumference is of one of the following four types of Figure 6.1, depending on the areas to be enclosed:

i) the standard double bubble $\Theta$,

ii) the band-lens $\Phi$,

iii) the symmetric two-component chain $\Omega$, or

iv) the double band $\Xi$ formed by three geodesic circles.

*Proof.* Clearly there cannot be a tiling on the infinite cylinder. As for the non-tiling minimizers, all proofs carry over from the proof of the main theorem. This is because locally, the cylinder looks like a section of the torus. And none of the proof strategies require "wrapping" around on the torus, where something could go on to infinity on the cylinder.

QEF

*Remark 6.5.* Note that on the infinite cylinder and the torus with longest side greater than $\sqrt{3}$, each of the four minimizers occurs. Since we have paramterized each of them, the phase plots in Figure 6.2 provide a complete description of the minimizers for each area pair.

## 6.8 Numerical comparisons between Minimizer Finalists

Now that we have established what the minimizers can be, we will do a numerical comparison to show which double bubbles occur as minimizers given a arbitrary area pairs. To do this, we plot perimeter versus area for each minimizer (using the parameterizations from the previous section) and numerically find the actual minimizer. Figure 6.2 contains 2-d plots showing where each minimizer occurs for the whole parameter space. Further, in Figure 6.23 we have plotted the intersections of the standard double bubble graph and the band-lens graph as evidence that these surfaces do in fact intersect in well-defined curves.

Figure 6.23: This graph of the intersection of the area for the standard double bubble and the band-lens shows that the boundaries between regions in the phase plots are likely to be smooth curves.

It is important to note that because we have not parameterized the octagon square, we can not *a priori* assume that each of these potential minimizers is actually a minimizer since the octagon square *might* beat everything else. Lemma 6.5 proves that the band-lens and the standard double bubble do in fact occur as minimizers.

# Chapter 7

# t3

**Charter.** We present a conjecture, based on computational results, on the area minimizing way to enclose and separate two arbitrary volumes in the flat cubic three-torus $\mathbf{T}^3$. For comparable small volumes, we prove that an area minimizing double bubble in $\mathbf{T}^3$ is the standard double bubble from $\mathbf{R}^n$.

## 7.1 Introduction

Our Central Conjecture 2.1 states that the ten different types of two-volume enclosures pictured in Figure 1 comprise the complete set of surface area minimizing *double bubbles* in the flat cubic three-torus $\mathbf{T}^3$. Our numerical results, summarized in Figure 7.2, indicate the volumes for which we conjecture that each type of double bubble minimizes surface area. Our main theorem, Theorem 4.1, states that given any fixed ratio of volumes, for small volumes, the minimizer is the standard double bubble. This result applies to any smooth flat Riemannian manifold of dimension three or four with compact quotient by its isometry group.

The *double bubble problem* is a two-volume generalization of the famous isoperimetric problem. The isoperimetric problem seeks the least-area way to enclose a single region of prescribed volume. About 200 BC, Zenodorus argued that a circle is the least-perimeter enclosure of prescribed area in the plane (see [19]). In 1884, Schwarz [47] proved by symmetrization that a round sphere minimizes perimeter for a given volume in $\mathbf{R}^3$. Isoperimetric problems arise naturally in many areas of modern mathematics. Ros [44] provides a beautiful survey.

Soap bubble clusters seek the least-area (least-energy) way to enclose and separate several given volumes. Bubble clusters have served as models for engineers, architects, and material scientists (Emmer [13] surveys some architectual applications, and the text by Weaire and Hutzler [57], an introduction to the physics of space-filling bubble clusters or *foams*, discusses numerous other applications).

**Existence and regularity** The surface area minimizing property of bubble clusters can be codified mathematically in various useful ways, using the rectifiable currents, varifolds, or $(\mathbf{M}, \epsilon, \delta)$-minimal sets of geometric measure theory (see [34]). In three dimensions, mathematically idealized bubble clusters consist of constant-mean-curvature surfaces meeting smoothly in threes at 120°along smooth curves, which meet in fours at a fixed angle of approximately 109° ([53, Theorems II.4, IV.5, IV.8], or see [34, Section 13.9]).

**Bubbles in the three-torus** In comparison with $\mathbf{R}^3$ and $\mathbf{T}^2$, the double bubble problem in $\mathbf{T}^3$ appears to be more difficult. In the torus it is not possible to push through a component bound like Hutchings', since a key step in his proof is to show that the double bubble has an axial symmetry. Nor is a variational bound after Wichiramala forthcoming, due to the additional topological complications in three dimensions. Until some new approach provides a component bound, there probably

will be no definitive results. Indeed, the single bubble for the three-torus is not yet completely understood, although there are partial results. The smallest enclosure of half of the volume of the torus was shown by Barthe and Maurey [2, Section 3] to be given by two parallel two-tori. Morgan and Johnson [36, Theorem 4.4] show that the least-area enclosure of a small volume is a sphere. Spheres, tubes around geodesics, and pairs of parallel two-tori are shown to be the only types of area minimizing enclosures for most tori by the work of Ritoré and Ros ([42, Theorem 4.2], [43]).

**Theorem about small volumes** Theorem 4.1 states that any sequence of area minimizing double bubbles of decreasing volume and fixed volume ratio has a tail consisting of standard double bubbles. The central difficulty is to bound the curvature. This accomplished, we show that the bubble lies inside some small ball that lifts to $\mathbf{R}^3$, where a minimizer is known to be standard [23]. The result extends to any flat 3- or 4-manifold with compact quotient by the isometry group.

Our proof goes roughly as follows. From the original sequence of double bubbles we generate a new sequence by rescaling the manifold at each stage so that one of the volumes is always equal to one. We can then apply compactness arguments and area estimates to the rescaled sequence to show that certain subsequences of translates have non-trivial limits. These limits are used to obtain a curvature bound on the original sequence. With such a bound, we can apply monotonicity to conclude that if the volumes are small, the double bubble is contained in a small ball. We conclude that it must be the same as the minimizer in $\mathbf{R}^3$ or $\mathbf{R}^4$, *i.e.* that it must be the standard double bubble by [23] or [41].

**Plan of the Paper.** Section 2 reviews the methods leading to our Central Conjecture 2.1 and to Figures 7.1 and 7.2. Section 3 surveys some subconjectures. Section 4 focuses on the proof of Theorem 1 on small volumes. Section 5 shifts from the cubic to other tori and discusses other conjectures

and candidates, including a "Hexagonal Honeycomb."

## 7.2 The Conjecture

**Generating Candidates.** Many possibilities for double bubbles in the three-torus $\mathbf{T}^3$ were proposed in brainstorming sessions by participants in the Clay/MSRI Summer School. In order to classify the candidates we used the following method. Starting with a standard double bubble, we imagined one of the two volumes growing until the bubble enclosing it wrapped around the torus and encountered an obstruction. Following the principles of regularity for bubble clusters, if a bubble collided with itself we opened the walls up, whereas if two different bubbles collided we allowed them to stick together. We then repeated this procedure for these new double bubbles, sometimes changing the perspective slightly or becoming a bit more fanciful (e.g. the Center Cylinder of Figure 7.1 or Gary Lawlor's Fire Hydrant of Figure 7.3, also known as "Scary Gary").

**Producing the Phase Diagram.** Brakke's *Surface Evolver* [5] was used to closely approximate the minimal area that a double bubble of each type needs to enclose specified volumes. Our initial simulations gave us the approximate surface area for each candidate double bubble, tested on partitions $v_1 : v_2 : v_3$ of a unit volume taken in increments of $0.01$. From the data obtained in these simulations, we found the least-area competitor for each volume triple. Figure 7.1 shows the candidates we found to be minimizing for some set of volumes. The phase diagram appearing in Figure 7.2 is the result of refining our initial computations along the boundaries with a 0.005 increment.

**Central Conjecture 1.** The ten double bubbles pictured in Figure 7.1 represent each type of surface area minimizing two-volume enclosure in a flat, cubic three-torus, and these types are minimizing

for the volumes illustrated in Figure 7.2.

**Comments.** One might expect that minimizers would be found among the various regularity-satisfying conglomerations of topological spheres and homotopically non-trivial tori, other possibilities being excessively complex. This was borne out in our computations. It is interesting to note, however, that not all of the simple possibilities appeared as minimizers (at least one of the enclosures in Figure 7.1 was always more efficient than the Transverse Cylinders pictured in Figure 7.3). The various double bubbles of Figure 7.3, while stable for a certain range of volumes, were never area minimizing. A challenging unsolved problem is to find all of the stable non-minimizing bubbles. Note that a given type from Figure 7.1 might be stable for a much wider range of volumes than those for which it actually minimizes surface area.

It is worth observing that all of the conjectured minimizers for the double bubble problem on $\mathbf{T}^2$ (a Standard Double Bubble, Band with Lens, Symmetric Chain, and Double Band) are echoed here in at least two ways. The Double Cylinder, the Slab Cylinder, the Double Slab, and the Cylinder String are $\mathbf{T}^2$ minimizers $\times$ $\mathbf{T}^1$. There are also more direct analogues, as is seen by comparing, for example, the three- and two-dimensional Standard Double Bubbles, or the Délauney and Symmetric Chains. See Corneli *et al.* [9] for more on the $\mathbf{T}^2$ minimizers.

## 7.3 Subconjectures

We now present a list of natural subconjectures, suggested either by the phase diagram or by examination of the pictures made with *Surface Evolver*.

One immediate observation is that the edges of our phase diagram appear to characterize single bubbles in $\mathbf{T}^3$.

**Conjecture 7.1 (Ritoré and Ros [42], [43], [44]).** The optima for the isoperimetric problem in a cubic $\mathbf{T}^3$ are the sphere, cylinder, and slab.

We still do not know proofs for the following intuitive conjectures about the double bubble problem (although Theorem 4.1 gives partial results on Conjecture 3.3):

**Conjecture 7.2.** An area-minimizing double bubble in $\mathbf{T}^3$ has connected regions and complement.

**Conjecture 7.3.** For two small volumes the standard double bubble is optimal.

**Conjecture 7.4.** For one very small volume and two moderate volumes, the Slab Lens is optimal.

**Conjecture 7.5.** The first phase transition as small equal, or close to equal, volumes grow is from the standard double bubble to a chain of two bubbles bounded by Délaunay surfaces.

Délaunay surfaces are constant-curvature surfaces of rotation, and as such have full rotational symmetry. From the *Surface Evolver* pictures, it appears that the conjectured surface area minimizers always have the maximial symmetry, given the constraints, a fact which leads to the following natural conjecture.

**Conjecture 7.6.** A minimizer is as symmetric as possible, given its topological type.

We will conclude this section with a proposition which represents the first step towards establishing a symmetry property. Specifically, we prove that for any double bubble, there is a pair of parallel planes (actually two-tori) that cut both regions in half. Hutchings [22, Theorem 2.6] used the fact that in $\mathbf{R}^n$ a double bubble has two perpendicular planes that divide both regions in half. This is an easy step in a difficult proof that the function that gives the least-area to enclose two given volumes is concave. Before proving a basic result of a similarly elementary flavor for the torus, we mention that we conjecture that the much deeper concavity result also holds:

**Conjecture 7.7.** The least area to enclose and separate two given volumes in the three-torus is a concave function of the volumes.

If one could prove Conjecture 3.7, one would then be able to apply other ideas in Hutchings' paper [22, Section 4] to obtain a functional bound on the number of components of a minimizing bubble.

**Proposition 7.1 (Deluxe Ham Sandwich Theorem).** In a rectangular torus, if a double bubble lies inside a cylinder $S^1 \times D^2$, then there is a plane that cuts both volumes in half.

*Proof.* This is a generalization of the standard argument for the ham sandwich theorem in Euclidean space. Assume that the identification occurs in the vertical direction. Take a circle in the $xy$ plane indexed by $\alpha \in [0, \pi]$. Then for each $\alpha$, rotate the surface by $\alpha$ in the $xy$ plane and consider the family of pairs of flat tori parallel to the $xz$ plane that are at distance 1/2 from each other. Then there is at least one such pair of planes that cuts the volume $V_1$ in half, for each $\alpha$. There may be an interval of such pairs for a given $\alpha$. However, some one parameter family of these planes may be chosen which varies continuously as a function of $\alpha$, and one such plane cuts $V_2$ in half. QEF

## 7.4 Small Volumes

Conjecture 7.3 stated that small volumes are best enclosed by a standard double bubble. Theorem 4.1 proves that for any fixed volume ratio, the standard double becomes optimal when the volumes are sufficiently small. This result holds for many flat three- and four-dimensional manifolds (and see Remark 7.2).

The standard double bubble consists of three spherical caps meeting at 120 degrees. (If the volumes are equal, the middle surface is planar.) It is known to be minimizing in $\mathbf{R}^3$ [23] and $\mathbf{R}^4$ [41].

**Theorem 7.1.** Let $M$ be a smooth flat Riemannian manifold of dimension three or four, such that $M$ has compact quotient by the isometry group. Fix $\lambda \in (0, 1]$. Then there is an $\epsilon > 0$, such that if $0 < v < \epsilon$, a perimeter-minimizing double bubble of volumes $v, \lambda v$ is standard.

*Remark 7.1.* Solutions to the double bubble problem exist for all volume pairs in manifolds with compact quotient by their isometry group. The proof is the same as in Morgan [34, Section 13.7].

For the proof we will regard a double bubble as a pair of 3- or 4−dimensional rectifiable currents,

$R_1$ and $R_2$, each of multiplicity one, of volumes $V_1 = \mathbf{M}(R_1)$ and $V_2 = \mathbf{M}(R_2)$. The total perimeter of such a double bubble is $\frac{1}{2}(\mathbf{M}(\partial R_1) + \mathbf{M}(\partial R_2) + \mathbf{M}(\partial(R_1 + R_2)))$. Here $\mathbf{M}$ denotes the mass of the current, which can be thought of as the Hausdorff measure of the associated rectifiable set (counting multiplicities). For a review of the pertinent definitions, see notes from Morgan's course at the Summer School [37] or the texts by Morgan [34] or Federer [14].

Before proceeding it is helpful to fix some notation. By the Nash and subsequent embedding theorems, we may assume $M$ is a submanifold of some fixed $\mathbf{R}^N$. We will consider a sequence of perimeter-minimizing double bubbles in $M$, containing the volumes $v$ and $\lambda v$, as $v \to 0$. For each $v$, $M_v$ will denote $s_v(M)$ in $s_v(\mathbf{R}^N)$, where $s_v$ is the scaling map that takes regions with volume $v$ to similar regions with volume 1. In particular, $s_v$ maps our perimeter-minimizing double bubble containing volumes $v$ and $\lambda v$ to a double bubble which we call $S_v$ which contains volumes 1 and $\lambda$, and which is of course perimeter-minimizing for these volumes.

We focus on the case of dimension three; the proof for dimension four is essentially identical.

**Lemma 7.1.** There is a $\gamma > 0$ such that if $R$ is a region in an open Euclidean 3-cube $K$ and $\mathrm{vol}(R) \leq \mathrm{vol}(K)/2$, then

$$\mathrm{area}(\partial R) \geq \gamma(\mathrm{vol}(R))^{2/3}.$$

*Proof.* Let $\gamma_0$ be such an isoperimetric constant for a cubical 3-torus, so that $\mathrm{area}(\partial P) \geq \gamma_0(\mathrm{vol}(P))^{2/3}$ for all regions $P \subseteq \mathbf{T}^3$. Such a $\gamma_0$ exists by the isoperimetric inequality for compact manifolds [34, Section 12.3]. Make the necessary reflections and identifications of the cube $K$ to obtain a torus containing a region $R'$ with eight times the volume and eight times the boundary area of $R$. The claim follows, with $\gamma = \gamma_0/2$. QEF

**Proof of Theorem 4.1.** The first step is to show that the sequence $S_v$, suitably translated and rotated, has a subsequence that converges as $v \to 0$ and has $V_1 \neq 0$ in the limit. Our argument also shows that there is a subsequence that converges to a limit with $V_2 \neq 0$, but does not show that

there is a subsequence where both volumes are non-zero in the limit. This is because while we are exerting ourselves trapping the first volume in a ball, the second one may wander off to infinity.

We first show the existence of a covering $\mathcal{K}_v$ of $M_v$ with bounded multiplicity, consisting of cubes contained in $M_v$, each of side-length $L$. Lemma 7.1 will give us a positive lower bound on the volume of the part of $R_1$ that is inside one of these cubes for each $S_v$. We will then apply a standard compactness theorem to show that a subsequence of the $S_v$'s converges.

Take a maximal packing by balls of radius $\frac{1}{4}L$. Enlargements of radius $\frac{1}{2}L$ cover $M_v$. Circumscribed cubes of edge-length $L$ provide the desired covering $\mathcal{K}_v$. To see that the multiplicity of this covering is bounded, consider a point $p \in M_v$. The ball centered at $p$ with radius $2L$ contains all the cubes that might cover it, and the number of balls of radius $\frac{1}{4}L$ that can pack into this ball is bounded, implying that the multiplicity of $\mathcal{K}_v$ is also bounded by some $m > 0$.

Now consider some such covering, with $L = 2$. By Lemma 7.1, there is an isoperimetric constant $\gamma$ such that

$$\text{area}(\partial(R_1 \cap K_i)) \geq \gamma(\text{vol}(R_1 \cap K_i))^{2/3},$$

and therefore, since $\max_k \text{vol}(R_1 \cap K_k) \geq \text{vol}(R_1 \cap K_i)$ for any $i$,

$$\text{area}(\partial(R_1 \cap K_i)) \geq \gamma \frac{\text{vol}(R_1 \cap K_i)}{(\max_k \text{vol}(R_1 \cap K_k))^{1/3}}. \tag{7.1}$$

Note that the total area of the surface is greater than $1/m$ times the sum of the areas in each cube, and the total volume enclosed is less than the sum of the volumes, so summing Equation 7.1 over all the cubes $K_i$ in the covering $\mathcal{K}_v$ yields

$$\text{area}(S_v) \geq \text{area}(\partial R_1) \geq m\gamma \frac{V_1}{(\max_k \text{vol}(R_1 \cap K_k))^{1/3}}$$

and

$$(\max_k(\text{vol}(R_1 \cap K_k)))^{1/3} \geq m\gamma \frac{V_1}{\text{area}(S_v)} \geq \delta > 0,$$

because $V_1 = 1$ and it is easy to show that $\text{area}(S_v)$ is bounded (since there is a bounded way of enclosing the volumes). Translate each $M_v$ so that the cube where the maximum occurs is centered

at the origin of $\mathbf{R}^N$, and rotate so that the tangent space of each $M_v$ at the origin is equal to a fixed $\mathbf{R}^3$ in $\mathbf{R}^N$. The limit of the $M_v$ will be equal to this $\mathbf{R}^3$. Since a cube with edge-length $L$ centered at the origin fits inside a ball of radius $2L$ centered at the origin, we have

$$\text{vol}(R_1 \cap B(0, 2L)) \geq \delta^3$$

for every $S_v$. By the compactness theorem for locally integral currents ([34, pp. 64,88], [48, Section 27.3, 31.2, 31.3]) we know that a subsequence of the $S_v$ has a limit, which we will call $D$, with the property that $\text{vol}(R_1) \geq \delta^3$. This completes the first step.

Since $D$ is contained in the limit of the $M_v$, namely, the copy of $\mathbf{R}^3$ chosen above, and each $S_v$ is minimizing for its volumes, a standard argument shows that the limit $D$ is the perimeter-minimizing way to enclose and separate the given volumes in $\mathbf{R}^3$ (cf. [34, 13.7]). In the limit, $V_2$ could be zero, in which case D is a round sphere. If both volumes are non-zero, D is the standard double bubble ([23] and [41], or see [34, Chapter 14]).

Our goal is now to prove that the double bubble of volumes $v$, $\lambda v$ lies inside a trivial ball, when $v$ is small enough. This can be accomplished using the monotonicity theorem for mass ratio [1, Section 5.1(1)], which implies that for a perimeter-minimizing bubble cluster, a small ball around any point on the surface contains some substantial amount of area. This will limit the number of disjoint balls we can place on the surface. The monotonicity theorem applies only to surfaces for which the mean curvature is bounded, *i.e.*, for which there is a $C$ such that for smooth variations

$$\frac{dA}{dV} \leq C.$$

Accordingly, the second major step in the proof is to obtain such bound on the curvature, for $v$ small. It suffices to show that all smooth variation vector fields have the property that changes in the volume of $S_v$ and in the area of $\partial S_v$ are controlled. Take a smooth variation vector field $F$ in $\mathbf{R}^n$ such that for $D$,

$$dV_1/dt = \int_{\partial R1} (F \cdot n)\, dA = c > 0$$

and

$$dV_2/dt = 0.$$

(Note that we need the first volume to be non-zero, or its variation could be zero.) For $v$ small enough the subsequence of $S_v$ headed towards the limit $D$ has the property that $dV_1/dt$ is approximately $c$ and $dV_2/dt$ is approximately 0.

By the argument in the first step, we can translate each $S_v$ similarly, so that a subsequence of the subsequence above converges to a minimizer $D'$ in $\mathbf{R}^3$ where the second volume is non-trivial. This time we take a smooth variation vector field $F'$, such that for $v$ small enough the subsequence of $S_v$ headed to $D'$ has the property that $dV_1/dt$ is approximately 0 and $dV_2/dt$ is approximately $c' > 0$. This proves that for this subsequence the change in volume is bounded below.

Now we need to show that the change in area is bounded above. This follows from the fact that every rectifiable set can be thought of as a varifold [34, Section 11.2]. By compactness for varifolds [1, Section 6], the $S_v$, situated so that the first volume does not disappear, converge as varifolds to some varifold, $J$. The first variation of the varifolds also converge, *i.e.*, $\delta S_v \to \delta J$, see [1]. The first variation of a varifold is a function representing the change in area. Therefore, far enough out in the sequence the change in area of the $S_v$ under $F$ is bounded close to the change in area of $J$ under $F$, which is finite. Similarly, the change in area of the $S_v$ under $F'$ is bounded.

We conclude that the mean curvature of $S_v$ is bounded for two independent directions in the two-dimensional space of volume variations, and hence for all variations. This completes the second step.

The third and final step is to show that all of the surface area is contained in some ball in $M_v$, of fixed radius for all $v$. Eventually, as $v$ shrinks and $M_v$ grows, this ball will have to be trivial in $M_v$. We will then use the result that the optimal double bubble in $\mathbf{R}^3$ is standard to show that our double bubble is standard as well.

As the $S_v$ are approaching the minimizer in $\mathbf{R}^3$, there must be a bound $A$ on the perimeters of

the $S_v$. By monotonicity of mass ratio [1, Section 5.1(1)], every unit ball centered at a point of $S_v$ contains perimeter $\delta > 0$. Therefore there are at most $A/\delta$ such disjoint balls.

We claim that the $S_v$ are eventually connected. There is an upper bound on the diameter of any component, $2A/\delta$. Since we are controlling curvature, our components cannot become too small. Since every unit ball contains at least $\delta$ area, we also have a lower bound on the area of each component, when unit balls are trivial. Unless eventually the $S_v$ are connected, you can arrange to get in the limit a disconnected minimizer in $\mathbf{R}^3$, a contradiction.

Hence $S_v$ is contained in a ball of radius $2A/\delta$ for all $v$. Since our original manifold has compact quotient by its isometry group, there is a radius such that balls in the original manifold of that radius or smaller are topologically trivial. Hence, as we expand the manifold, eventually balls of radius $2A/\delta$ can be lifted to $\mathbf{R}^3$, which means that they are Euclidean. Hence, $S_v$ is eventually contained in a Euclidean ball, and is therefore the standard double bubble ([41], [23], [34, Chapter 14]).

Finally, since $S_v \subset M_v$ is simply a scaled version of the original double bubble in $M$, we conclude that the original double bubble is standard as desired. QEF

*Remark 7.2.* Given $n$, $m$, similar arguments show that for any smooth $n$-dimensional Riemannian manifold with compact quotient by the isometry group, given $0 \leq \lambda \leq 1$, there are $C$, $\epsilon > 0$, such that for any $0 < v < \epsilon$, a minimizing cluster with $m$ prescribed volumes between $\lambda v$ and $v$ lies inside a ball of diameter at most $Cv^{1/n}$.

To further deduce that the cluster smoothly approximates a Euclidean minimizer would require knowing that convergence weakly and in measure, under bounded mean curvature, implies $C^1$ convergence, as is known for hypersurfaces without singularities ([1, Section 8], see [35, Section 1.2])

## 7.5 Special Tori

Changing the shape of the torus, by stretching it or by skewing some or all of its angles, would certainly change the phase diagram of Figure 7.2:

**Conjecture 7.8.** In the special case of a very long $T^3$ the Double Slab is optimal for most volumes.

Special tori may have special minimizers:

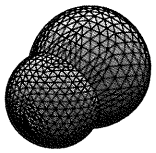
**Conjecture 7.9.** For the special case of a torus based on a relatively short $\frac{\pi}{3}$-rhombic right prism, the Hexagonal Honeycomb prism of Figure 7.4 is a perimeter-minimizing double bubble for which both regions and the exterior each have one third the volume, or when two volumes are equal and the third is close.

Indeed, for such volumes the Hexagonal Honeycomb ties the Double Slab, just as in the $\frac{\pi}{3}$-rhombic two-torus a Hexagonal Tiling ties the Double Band [9].

In the *triple bubble problem* for the Face Centered Cubic (FCC) and Body Centered Cubic (BCC) tori, if not for the standard cubic torus, we would expect to find minimizers that lift to $\mathbf{R}^3$ as periodic foams with cells of finite volume. For example, the Weaire-Phelan foam would be expected to appear as lifts of some solutions to the *seven* bubble problem in the BCC torus. The Weaire-Phelan foam, a counterexample to Kelvin's conjectured best way to divide space into unit volumes ([56], [27]; see [34, Chapter 15], [6]). Kelvin's foam might appear as a minimizer for the seven bubble problem in the FCC torus. It is interesting to note that the Weaire-Phelan foam has essentially the same shape as chlorine hydrate crystale.

In contrast with the triple bubble problem, it would be extremely unlikely if there was a solution to the double bubble problem in any torus that lifted to a division of $\mathbf{R}^3$ into finite volumes, since by regularity, singular curves meet in fours. This means that singular points look locally like the cone over a tetrahedral frame, and hence have four volumes coming together. Since a region will never be adjacent to another component of the same region (because the dividing wall could be removed

to decrease area and maintain volumes), a foam generated using a fundamental domain coming from a double double in the three-torus would have to exhibit the strange property that the singular curves never meet.



**Conjecture 7.10.** There are no least-area divisions of $\mathbf{T}^3$ into three volumes that lift to a foam in $\mathbf{R}^3$.

This conjecture suggests in addition that it is not likely that there will be are any other special minimizers.

**Conjecture 7.11.** The double bubbles of Figure 7.1 together with the Hexagonal Honeycomb of Figure 7.4 comprise the complete set of area minimizing double bubbles for all three tori.

As a final remark, in light of the fact that the adding more bubbles seems likely to produce many interesting candidates, we would like to mention one final conjecture.

**Conjecture 7.12.** For the triple bubble problem in a cubic $\mathbf{T}^3$ in the case where one of the volumes is small, the minimizers will look like the double bubbles of Figure 7.1 with a small ball attached. The phase diagram will look just like our Figure 7.2.

# conjectural epilog

These are some of the thoughts I have had while working on this thesis.

Any resembalence of the things discussed here to the current views of my collaborators or of the mathematical community at large or to the actual facts of the matter has to be regarded as coincidental at best.

**Symmetry and algebraic structure** Comparing the results from the various chapters leads to the conjecture that area-minimizing double bubbles in constant curvature spaces always have some of the same symmetries as the space, and more generally maximize symmetry in some sense.

We now consider the possibility that by seeking to maximize symmetry, bubble clusters not only take on some of the symmetries of the ambient, but also exhibit certain symmetries (*i.e.* invariants) associated with their own 'intrinsic' algebraic structure.

If this is the case, the algebraic structure of bubble clusters is bound to be of interest. Recall from Chapter 4 that the standard double bubble is invariant under inversion in the separating cap. For standard bubble clusters with more components, we can again move between adjacent bubbles by inversions – although doing so sometimes requires two moves, since if $B_3$ curves into $B_2$, we might send a point $p \in B_1$ to a point $q \in B_3$ by inversion in the wall separating $B_1$ and $B_2$; all such '$q$'s are however mapped into $B_2$ by inversion in the wall separating $B_2$ and $B_3$. When there are more than two bubbles, points fixed by the entire group of these (generalized) adjacency transformations

(or, the *cluster group*) are always in the singular set. When there are more than four bubbles, there may be no points that are fixed by the entire cluster group, but all singular curves are fixed by some subgroup of order three, and all singular points are fixed by some subgroup of order four.

The intrinsic algebraic structure of foams may may be particularly interesting (or, possibly, but not likely, particularly easy to understand) since periodic foams have a natural group acting on them already.

Maximizing symmetry here should for the time being be understood in a weak sense, say, maximizing symmetry while taking into consideration certain other factors. The cluster group may be hard to define or even meaningless in clusters that have non-contractible components (although I suspect that that won't be much of an obstacle). When the boundary surfaces are constant-mean-curvature sufaces other than pieces of spheres, things certainly *sound* less attractive, but the important ideas still seem to carry through.

At the bottom of this line of inquiry lies the fundamental assumption that there are no factors besides symmetry that can come into play to reduce area.

As one specific example that might give evidence as to the truth or falsity of this assumption, here is a problem that I think is open: the Kelvin foam *seems* to have 'more symmetry' than the Weaire-Phelan foam that takes less area. However, it might be that the Weaire-Phelan foam actually has more symmetries when one looks at its cluster group. Decide this question.

**Is the $m$-bubble problem *inductive*?** The standard double bubble is clearly a relaxation of the solution to the single bubble problem in space minus a round ball. In addition, it seems that all of the other conjectured minimizers for the double bubble problem in $\mathbf{T}^k$ $(k = 1, 2, 3)$ are relaxations of the solution to the single bubble problem in the torus minus a single bubble solution. This seems to be plainly obvious, albeit ever-so-hard to prove, for everything but the hexagonal tiling and hexagonal honeycomb. And upon further reflection it does not seem at all unlikely that the hexagonal tiling (resp. hexagonal honeycomb) is a relaxation of the solution to the single bubble problem in a 'nut',

*i.e.* a hexagonal torus minus a round disk (resp. tubular neighborhood of a short geodesic).

These considerations lead to the following *meta-Conjecture*.

**Meta-Conjecture.**

1. The solution to the $m$-bubble problem in any space of constant curvature $C$ is bounded by regularity satisfying relaxations of some collection of (a) tubular neighborhoods of totally geodesic submanifolds (counting points as a degenerate case) and (b) tubular neighborhoods of totally geodesic submanifolds (not allowing points this time) regarded as manifolds with boundary that then have some noncontractible (with respect to their boundary) holes drilled out of them; moreover,

2. the boundary of the union of the closure of the holes in each tubular neighborhood $T_0$ in (1b) bounds a totally geodesic submanifold of $T_0$ (again not allowing points); and, ultimately,

3. the problem is inductive in the sense that the $m$-bubble problem is given by relaxing the solution to the 1-bubble problem for the current with free boundary given by designating some solution to the $(m-1)$-bubble problem in $C$ as boundary.

# appendices

## A Algebraic preliminaries

**Definition A.1.** A *vector space* is a quadruple $(X, F, +, *)$, where $X$ is a set, $F$ is a field, and $+$ and $*$ are operations such that

i. $\forall x \in X, f \in F : x * f \in X$,

ii. $\forall x, y \in X : x + y \in X$.

Furthermore, addition $(+)$ is commutative, there exists an additive identity (written 0) and there are additive inverses. Scalar multiplication $(*)$ is associative and distributes over addition both ways.

We write $V = (X, F, +, *)$, and when we say $v \in V$ we mean $v \in X$. The field $F$ is called the *base field*. In this thesis, the base field is usually the real or the complex numbers.

The notion of a *basis* and of how to do computations with a basis (using *matrices*) are assumed to be familiar to the reader, at least for finite dimensions.

**Definition A.2.** A *bilinear form* on a finite dimensional vector space $V$ is a map $b$ from $V \times V$ into the base field that is linear in each factor. If we chose a basis for the vector space, then the bilinear form is given by matrix multiplication as follows: $b : (x, y) \mapsto y^T B x$, for some matrix $B$.

**Remark A.1.** The two dimensional case is

$$((x_1, x_2), (y_1, y_2)) \mapsto \begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = ax_1y_1 + bx_1y_2 + cx_2y_1 + dx_2y_2.$$

**Definition A.3.** An *inner product* on a vector space is a bilinear form that is also *positive definite* (which means that $b(x, x) \geq 0$ and is equal to zero only when $x = 0$) and *symmetric* ($b(x, y) = b(y, x)$).

**Remark A.2.** Given an abstractly defined linear map on a finite dimensional vector space, to determine the entries of the matrix representing this map it suffices to compute the action of the map on a basis. Similarly for bilinear forms and thus for inner products. The matrix representing a bilinear form $b$ with respect to the basis $\{x_i\}_{i=1}^n$ is $(b(x_i, x_j))$.

**Definition A.4.** A *vector space isomorphism* is a linear, bijective map between two vector spaces.

**Definition A.5.** The *dual* of a vector space $V$ is the set of linear maps from $V$ into the base field. We denote the dual of $V$ by the symbol $V^*$.

**Remark A.3.** It is easy to check that vector space duals are themselves also vector spaces. It is also easy to check that in the finite dimensional case a vector space is isomorphic to its dual. This is not generally true for infinite dimensional vector spaces.

**Definition A.6.** A *group* is a set $X$ together with a binary operation $*$ with the properties

i. $\forall x, y, z \in X : x * (y * z) = (x * y) * z$,

ii. $\exists e \in X : \forall x \in X : e * x = x * e = x$,

iii. $\forall x \in X : \exists x^{-1} \in X : x * x^{-1} = x^{-1} * x = e$,

We write $G = (X, *)$ and when we say $g \in G$ we mean $g \in X$. It is easy to deduce that a vector space is an *additive group* (that is, the operation $(+)$ in Definition A.1 plays the role of $(*)$ in Definition A.6). We now define another important example:

**Definition A.7.** The *symmetric group on $n$ elements* $\mathfrak{S}^n$ is equal to the set of permutations of $n$ elements together with the operation of composition.

**Remark A.4.** So, for example, $\mathfrak{S}^3$ can be written down as $\{(), (12), (23), (13), (123), (321)\}$ (do nothing, sent 1 to 2 and 2 to 1, send 2 to 3 and 3 to 2, etc.) and then it is easy to check that with the operation $\circ$, $\mathfrak{S}^3$ really is a group (for example, $(123)\circ(321) = ()$, so $(321) = (123)^{-1}$). The symmetric group is important in the theory of determinants (and many other places). Indeed, using the *sign* of permutations (even if the an even number of elements are permuted, odd if an odd number of elements are permuted) it is not too difficult to show (or at least beleive) that for an $n \times n$ matrix $A$,

$$det(A) = \sum_{\sigma \in \mathfrak{S}^n} \text{sign}(\sigma) A_{\sigma 1,1} \cdot \ldots \cdot A\sigma n, n);$$

see [20, Chapter 5] for the details.

**Definition A.8.** If a group $G$ acts on a set $X$ (in the sense that $\mathfrak{S}^n$ acts on the set $\{1, \ldots, n\}$) the *orbit* of a point $x \in X$ is defined to be the set of points in $X$ that are hit by applying elements of $G$ to $x$ (with repeated application of the same element allowed).

# B Topological preliminaries

**Definition B.1.** A *topological space* is a pair $(X, \tau)$ such that $\tau$ is comprised of subsets of $X$ and has the further additional properties

i. $\emptyset \in \tau$ and $X \in \tau$.

ii. finite intersections of elements of $\tau$ are again in $\tau$

iii. arbitrary unions of elements of $\tau$ are again in $\tau$.

A collection of subsets $\tau$ satisfying these conditions make $\tau$ into a *topology*. The elements of $\tau$ are then called the *open sets of $X$ in the $\tau$ topology*.

**Remark B.1.** If $T = (X, \tau)$ is a topological space, when we say $p \in T$ we mean $p \in X$.

**Definition B.2.** A map between topological spaces is *continuous* if the inverse image of every open set is an open set.

**Definition B.3.** A map between topological spaces is a *homeomorphism* if it is a continuous bijection such that in addition the image of every open set is an open set. (So, it is a bijection of points and it induces a bijection on open sets.)

Since they are a bijection of points and sets, we conclude that homeomorphisms respect topological structure. In this sense it would be appropriate to consider them to be 'topological isomorphisms'.

We will need the following two 'special' definitions.

**Definition B.4.** A topological space $T$ is *Hausdorff* if it has the property that any pair of distinct points $p, q \in T$ belong to disjoint open sets.

(Spaces without this property include easy examples like $X = \{a, b, c\}, \tau = \{\emptyset, \{a\}, \{a, b, c\}\}$ and more complicated examples, like $(\mathbf{R} \cup (0, 1) \subset \mathbf{R}^2, \{U; U \cap \mathbf{R}$ such that $U$ is open in the metric topology on $\mathbf{R}$ and if $p \in U$ then $(U \cap \mathbf{R}) \cup 0$ is a neighborhood of 0 in $\mathbf{R}\})$. In general we will exclude non-Hausdorff spaces like this because they cause trouble.)

**Definition B.5.** A topological space $T = (X, \tau)$ is *paracompact* if there is a countable set $\mathcal{B}$ of open sets in $\tau$ with the property that every open set in $\tau$ is the union of elements of $\mathcal{B}$.

**Remark B.2.** In general, a set $\mathcal{B}$ that contains the set of open sets is called a basis for the topology. Every topology has a basis (any topology contains all of its open sets). We note that the basis *condition* is equivalent to the condition that any point in an open set is also in an element of $\mathcal{B}$. The *word* paracompact is synonymous with the phrase *second countable*.

This begs the question, what was *first countable*? This condition is not needed elsewhere in this thesis, but so that the reader leaves with a satisfied mind, here it is anyway: each point in $X$ must

have the property that there is a countable set $\mathcal{B}_p$ of open sets containing $p$ such that every open set containing $p$ also contains an element of $\mathcal{B}_p$. The set $\mathcal{B}_p$ is then called a *local basis*.

**Definition B.6.** A *metric space* is a pair $(X, d)$ such that $d$ is a function defined on $X \times X$ with the following additional properties:

i. $0 \leq d(x, y) < \infty$

ii. $d(x, y) = 0 \Leftrightarrow x = y$

iii. $d(x, y) = d(y, x)$

iv. $d(x, y) \leq d(x, z) + d(z, y)$

**Definition B.7.** The set of *metric balls* $\{\mathbf{D}_x(r) = \{y \in X; d(y, x) < r\}; x \in X, 0 \leq r \in \mathbf{R}\}$ form a topology for $X$. This is called the *metric topology*.

**Remark B.3.** We remark that $\mathbf{R}^n$ with the metric topology (the *standard topology on* $\mathbf{R}^n$) is both paracompact and Hausdorff. Metric balls with a rational radius centered at rational points form a countable basis for the topology, and by chosing $\rho$ small enough, any two points $p$ and $q$ can be enclosed in disjoint metric balls of radius $\rho$.

The dividing line between topology and geometry moves around a lot. It shows up right here this time.

# C Geometric Preliminaries

For our purposes, Riemannian geometry is the study of

I manifolds, with

II a differentiable structure,

III admitting the definition of vector fields,

IV which can themselves be differentiated;

V with also a notion of lengths and angles associated with vectors based at a point in the manifold,

VI leading to the notion of shortest paths in the manifold,

VII and to many other results having to do with global structure.

Item VII includes answers to questions like 'What are the least surface area objects in my manifold?'.

## Geometry of manifolds

Manifolds generalize the idea of parametrized surfaces. This is useful, because, for example, it is all fine and good to study the upper-hemisphere, considered as the graph of $\sqrt{r^2 - x_2 - y^2}$ over a disk of radius $r$, but if we can't talk coherently about the whole sphere, our mathematical lives will be considerably less interesting. Manifold theory lets us talk about the whole sphere and about lots of other things. One of the central ideas in the definition of a smooth manifold is that it stitches together 'local parameterizations' in a nice way.

**Definition C.1.** A *manifold* is a paracompact Hausdorff topological space such that about each point $p \in M$ there is some open set $U \ni p$ such that there exisits a homeomorphism $\varphi$ from $U$ to $\mathbf{R}^n$.

The pairs of open sets and homeomorphisms $(U, \varphi)$ from Definition C.1 are called *charts*. If we say that a point $p$ is in a chart $(U, \varphi)$, what we mean is that $p \in U$. All of the charts taken together are called an *atlas*. Our atlases are henceforth assumed to be *complete* in the sense that they are never contained in some other atlas. This is a viable assumption, because we can keep adding in charts until we complete the atlas. We denote the complete atlas for our manifold by $\mathcal{A}$.

We write $M$ for the triple $(X, \tau, \mathcal{A})$, and when we say $p \in M$ we mean $p \in X$. Because this convention is so prevalently and widely used, it is sometimes easy to lose sight of the important fact that the topology $\tau$ as well as the point-set $X$ are fixed; in particular, you should always be ready to ask 'with what topology?' if someone describes a manifold to you in terms of its point set only and their choice of topology was not obvious.

The atlas makes it possible to compute things; we can use a chart $(U, \varphi)$ to define a coordinate system on $U$ which we then use to study small pieces of the manifold analytically. If we are interested in what is going on around a point $p \in U \subset M$, we can assume $p$ is mapped by the associated homeomorphism $\varphi$ to $0 \in \mathbf{R}^n$, since wherever it is mapped we can compose with a translation to recenter $\mathbf{R}^n$ on the image of $p$. We then make the following extremely useful definition.

**Definition C.2.** If $x_1, \ldots, x_n$ are the functions which give the coordinates of the point $x$ in $\mathbf{R}^n$, we say that the set of functions $x_1 \circ \varphi, \ldots, x_n \circ \varphi$ are *local coordinates centered at p* or just *local coordinates at p*.

**Remark C.1.** For notational convenience, we will frequently make use of the alternate notation for local coordinates at $p$, namely $u_1 = x_1 \circ \varphi, \ldots u_n = x_n \circ \varphi$.

In order to compute anything very interesting, we need some more structure.

**Definition C.3.** A manifold's atlas is a *differentiable structure on the manifold* if the charts of Definition 1 satisfy the following property: if $(U_1, \varphi_1)$ is a chart about $p$ and $(U_2, \varphi_2)$ is a chart about $q$ then whenever $U_1 \cap U_2 \neq \emptyset$, the map $\varphi_1 \circ \varphi_2^{-1}$ from $\varphi_2(U_1 \cap U_2) \subset \mathbf{R}^n$ onto $\varphi_1(U_1 \cap U_2) \subset \mathbf{R}^n$ is differentiable.

We say a manifold has a $C^k$ *structure* if the transition functions $\varphi_j \circ \varphi_i^{-1}$ are $k$ times continuously differentiable. We say a manifold has a *smooth* structure if the transition functions are infinitely differentiable.

The existence of differentiable structures allows us to talk about differentiable and smooth maps between manifolds.

**Definition C.4.** If $M_1$ and $M_2$ are manifolds (say, of dimensions $m$ and $n$ respectively) then $f : M_1 \to M_2$ is said to be a *differentiable map* if for every chart $(U, \varphi)$ of $M_1$ and every chart $(V, \psi)$ of $M_2$ such that $f(U) \subset V$ the map $\psi \circ \varphi^{-1}$ from $\varphi(U) \subset \mathbf{R}^m$ into $\psi(V) \subset \mathbf{R}^n$ is $C^k$ as a map between Euclidean spaces (see section 2.1.1).

If we take $M_1 = J$ to be an open interval in $\mathbf{R}$ then a *differentiable curve* in $M_2$ is any differentiable map $\gamma$ of a closed interval in $M_1$ into $M_2$. For the rest of the appendix, curves will always be differentiable.

**Definition C.5.** Let $\gamma : [a, b] \to M$ be a smooth curve in $M$ that passes through the point $p$ at the time $t_0$. Let $\mathcal{F}$ be the set of differentiable functions from $M$ to $\mathbf{R}$. The *tangent vector to $\gamma$ at $p$* is a linear map $L_{\gamma,p}$ defined on $\mathcal{F}$ by the rule

$$L_{\gamma,p}(f) = \left.\frac{df(\gamma(t))}{dt}\right|_{t_0} \in \mathbf{R}.$$

**Remark C.2.** Tangent vectors give us a directional derivative on functions (we can use them to compute how fast a function is changing in a given direction). We can conveniently compute the tangent vector to a curve $\gamma$ at $p$ in terms of local coordinates at $p$. If $\gamma_i(t) = x_i \circ \varphi \circ \gamma(t)$ are the coordinates of the curve, and we know $f$ as a function of local coordinates at $p$, then the chain rule tells us that

$$\begin{aligned}\left.\frac{df(\gamma(t))}{dt}\right|_{t_0} &= \sum_{i=1}^{n} \left.\frac{df}{d(x_i \circ \varphi \circ \gamma)}\right|_{t_0} \left.\frac{d\gamma_i(t)}{dt}\right|_{t_0} \\ &= \sum_{i=1}^{n} \left.\frac{df}{d(x_i \circ \varphi)}\right|_{p=\gamma(t_0)} \left.\frac{d\gamma_i(t)}{dt}\right|_{t_0}\end{aligned}$$

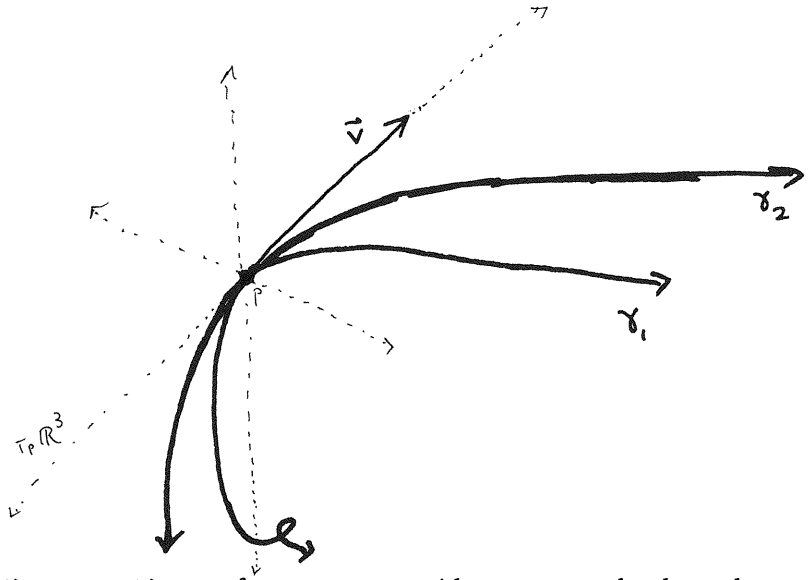

Figure 7.5: Picture of tangent space with two curves that have the same tangent vector.

$$= \sum_{i=1}^{n} \frac{df}{du_i}\bigg|_{p=\gamma(t_0)} \frac{d\gamma_i(t)}{dt}\bigg|_{t_0}.$$

**Definition C.6.** The *tangent space of $M$ at $p$*, denoted $T_pM$, is equal to the set of all tangent vectors of curves in $M$ through $p$.

**Remark C.3.** The computation of Remark C.2 shows that the tangent space at a point is an $n$-dimensional real vector space with basis $\{\frac{d}{du_i}\big|_p\}$. We frequently will identify this space with $\mathbf{R}^n$.

The functional definition of tangent vectors and tangent spaces given here is slightly less popular than the more geometric-seeming definition from subsection 2.1.1 in the text that identifies curves whose tangent vectors are the same to make the tangent space. The computation of Remark C.2 shows that these two definitions are equivalent, since if we regard tangent vectors as being given by a linear combination of '$\frac{d}{du_i}$'s, then to get a given tangent vector we must specify the right '$\frac{d\gamma_i(t)}{dt}$'s, that is, we must specify the derivatives found upon differentiating a curve in some equivalence class; whereas on the other hand, clearly if we specify on equivalence class of curves, we get a functional tangent vector (something that differentiates functions) using the given formula.

**Definition C.7.** The *tangent bundle $TM$* of a manifold is the union over $x$ in $M$ of all the the tangent spaces.

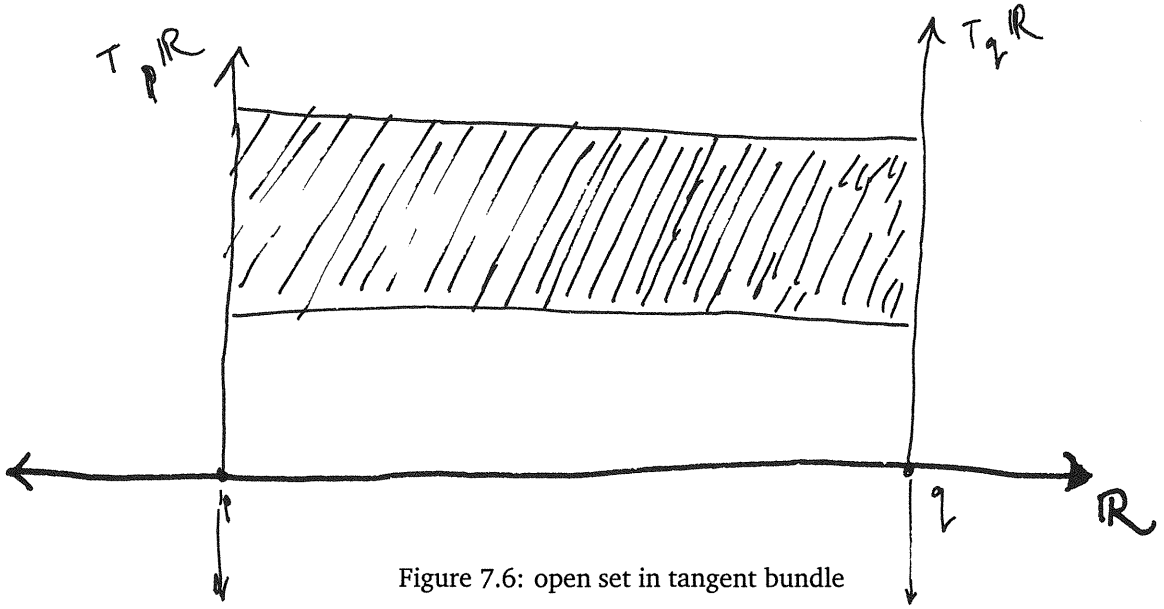

Figure 7.6: open set in tangent bundle

**Definition C.8.** We define the *standard projection operator* $\pi$ from the tangent bundle to the manifold which takes each vector to its base point.

**Remark C.4.** Typically we want to think of the tangent bundle as a manifold with a differentiable structure that can tell us something about the base manifold, not just as the set of all vectors tangent to the manifold 'bundled together' indiscriminately. We distiguish the points in $TM$ carefully by writing $TM = \{(p, v) : p \in M, v \in T_pM\}$; then a natural topology on $TM$ is induced by the topology of $M$, namely, an open set in $TM$ is given by $U \times V$ where $U$ is an open set of $M$ that comes from a chart and $V$ is an open set of $\mathbf{R}^n$. We are using the identification of the tangent spaces and $\mathbf{R}^n$. The picture is easy in one dimension; see Figure 7.6. The tangent bundle also has a natural smooth structure on it, since if $(U, \varphi)$ is a chart on $M$ then every element $u \in \{(p, v) : p \in U, v \in T_pM\} \subset TM$ can be written in the form $u = \sum_{i=1}^{n} a_i(v) \left.\frac{d}{du_i}\right|_{p=\pi(v)}$. The map

$$T_pM \ni u \mapsto (u_1(\pi(v)), \ldots, u_n(\pi(v)), a_1(v), \ldots, a_n(v)) \in \mathbf{R}^{2n}$$

is a homeomorphism from $\{(p, v) : p \in U, v \in T_pM\}$ to $\mathbf{R}^{2n}$.

One checks that the conditions of Definition C.3 are satisfied ([49, volume I, page 3-32]).

**Definition C.9.** A *vector field* on a manifold consists of a choice of one vector from each tangent space. Hence vector fields are functions from a base manifold to its tangent bundle. We write $\text{vect}(M) = \{\text{vector fields on } M\}$. Another way to talk about a vector field to call it a *section* of the tangent bundle, where the word section means a map $s$ from the manifold to the bundle such that $\pi \circ s$ is the identity. If $\mathcal{V}$ is a vector field on $M$, $\mathcal{V}|_x$ denotes the vector associated with $T_x M$.

**Remark C.5.** Since tangent vectors are differential operators, vector fields are too; they take differentiable functions defined on the manifold to functions on the manifold given by the directional derivatives specified by the tangent vector at each point. They also allow us to compute lots of other things, but as before, to compute anything really interesting, we want more structure.

**Definition C.10.** Refering to DefinitionC.3, we note that the smooth structure on $TM$ developed in Remark C.4 makes it possible to define

$$\text{vect}^k(M) = \{C^k \text{ vector fields on } M\}$$

and

$$\text{vect}^\infty(M) = \{C^\infty \text{ vector fields on } M\}.$$

We will usually just write $\text{vect}(M)$ and understand a degree of smoothness appropriate for the needs at hand.

**Remark C.6.** The idea of the nabla coming up is that somehow the derivative of a smooth section of $TM$ with respect to a smooth section of $TM$ is again a smooth section of $TM$. We don't necessarily expect that to happen; we have to work just the right way. (See Kobaishi and Nomizu [39] for a much more general way to go about doing this.)

**Definition C.11.** A *connection* is a map $\nabla : TM \times \text{vect}(M) \to TM$ which satisfies the following properties:

i. if $\xi \in TM, \mathcal{V} \in \text{vect}(M)$, then $\nabla(\xi, \mathcal{V})$ is in the same tangent space as $\xi$.

ii. if $a, b \in \mathbf{R}^n$, $x \in M$, $\xi, \eta \in T_x M$, and $\mathcal{V} \in \text{vect}(M)$, then

$$\nabla(a\xi + b\eta, \mathcal{V}) = a\nabla(\xi, \mathcal{V}) + b\nabla(\eta, \mathcal{V}) \tag{C.1}$$

iii. if $x \in M$, $\xi \in T_x M$, $\mathcal{V}, \mathcal{W} \in \text{vect}(M)$, and $f \in C^1(M)$, then

$$\nabla(\xi, \mathcal{V} + \mathcal{W}) = \nabla(\xi, \mathcal{V}) + \nabla(\xi, \mathcal{W}) \tag{C.2}$$

$$\nabla(\xi, f\mathcal{V}) = (\xi f)(\pi(\xi))\mathcal{V}|_{\pi(\xi)} + f(\pi(\xi))\nabla(\xi, \mathcal{V}) \tag{C.3}$$

iv. $\nabla$ is smooth in the sense that if $\mathcal{V}, \mathcal{W} \in \text{vect}^\infty(M)$ then $\cup_{x \in M} \nabla(\mathcal{V}|_x, \mathcal{W})$, which we call $\nabla(\mathcal{V}, \mathcal{W})$, is again in $\text{vect}^\infty(M)$.

**Remark C.7.** When it is clear from context where we are working, or when we want to be mobile, we use this more casual notation for the second part of item (iii):

$$\nabla(\xi, f\mathcal{V}) = (\xi f)\mathcal{V} + f\nabla(\xi, \mathcal{V}) \tag{C.4}$$

where it is understood that everything on the right-hand side that needs to be is to being evaluated at $\pi(\xi)$.

Definition C.11 is far from being the most general definition of a connection. In some ways it is much more like the definition of what is called a *covariant derivative associated with a connection*. We leave such matters aside; this definition will suffice for all our needs in this thesis. At any rate, it is clear from item (iii) above that whatever it is called, we now have a method for differentiating vector fields.

At this point we note that we must have

$$\nabla\left(\frac{d}{du_k}, \frac{d}{du_j}\right) = \sum_{i=1}^{n} \Gamma_{jk}^i \frac{d}{du_i} \tag{C.5}$$

for some set of '$\Gamma_{jk}^i$'s. (The order and placement of the various indices here is traditional.) If we 'know' a connection somehow, we know its action on all of $TM \times \text{vect}(M)$ and we can compute

these; alternatively, and more realistically, we can just specify them to begin with and get some connection as a result. In particular, this shows that connections exist.

In order to actually compute $\nabla(\xi, \mathcal{V})$ all we need to know is $\mathcal{V}$ restricted to some smooth curve $\gamma$ through $p = \pi(\xi)$ with tangent vector $\xi$ at $p$. In terms of the basis for the tangent space at $p$ that we chose in Remark C.1, $\xi = \sum_{i=1}^{n} \xi_i \frac{d}{du_i}$.

By the linearity in the first component (condition (ii) above) this means that

$$\nabla(\xi, \mathcal{V}) = \sum_{i=1}^{n} \xi_i \nabla(\frac{d}{du_i}, \mathcal{V}).$$

Since we know $\mathcal{V}$ along $\gamma$, for each $q \in \gamma$ we can express $\mathcal{V}$ at each point in terms of local coordinates at $q$ as $\mathcal{V}|_q = \sum_{i=1}^{n} \eta_i(q) \frac{d}{du_i}|_q$, or, more informally, $\mathcal{V} = \sum_{i=1}^{n} \eta_i \frac{d}{du_i}$. Combining this expression with the previous, we have

$$\nabla(\xi, \mathcal{V}) = \sum_{i=1}^{n} \xi_i \nabla \left( \frac{d}{du_i}, \sum_{j=1}^{n} \eta_j \frac{d}{du_j} \right).$$

We now enter a long chain of manipulations that will in the end give us a nice formula for $\nabla(\xi, \mathcal{V})$. First applying the first part of condition (iii) above

$$\sum_{i=1}^{n} \xi_i \nabla \left( \frac{d}{du_i}, \sum_{j=1}^{n} \eta_j \frac{d}{du_j} \right) = \sum_{i=1}^{n} \xi_i \sum_{j=1}^{n} \nabla \left( \frac{d}{du_i}, \eta_j \frac{d}{du_j} \right)$$

(and then the second part of condition (iii))

$$= \sum_{i=1}^{n} \xi_i \sum_{j=1}^{n} \left( \left( \frac{d\eta_i}{du_i} \right) \frac{d}{du_j} + \eta_j \nabla \left( \frac{d}{du_i}, \frac{d}{du_j} \right) \right)$$

(and the definition of the '$\Gamma_{jk}^{i}$'s)

$$= \sum_{i=1}^{n} \xi_i \left( \sum_{j=1}^{n} \left( \left( \frac{d\eta_j}{du_i} \right) \frac{d}{du_j} + \eta_j \sum_{k=1}^{n} \left( \Gamma_{ji}^{k} \frac{d}{du_k} \right) \right) \right)$$

(collecting like terms)

$$= \sum_{i=1}^{n} \left( \sum_{j=1}^{n} \left( \left( \xi_i \frac{d\eta_j}{du_i} \right) \frac{d}{du_j} + \sum_{k=1}^{n} \left( (\xi_i \eta_j \Gamma_{ji}^{k}) \frac{d}{du_k} \right) \right) \right)$$

(rewriting the summation without quite so many parentheses)

$$= \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \left( \xi_i \frac{d\eta_j}{du_i} \right) \frac{d}{du_j} \right) + \sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{k=1}^{n} \left( (\xi_i \eta_j \Gamma_{ji}^{k}) \frac{d}{du_k} \right)$$

(renaming one of the indices of summation does not effect the sum)

$$= \sum_{i=1}^{n}\sum_{k=1}^{n}\left(\left(\xi_i \frac{d\eta_k}{du_i}\right)\frac{d}{du_k}\right) + \sum_{i=1}^{n}\sum_{j=1}^{n}\sum_{k=1}^{n}\left((\xi_i\eta_j\Gamma_{ji}^k)\frac{d}{du_k}\right)$$

(and now rearranging the summation)

$$= \sum_{k=1}^{n}\left(\sum_{i=1}^{n}\left(\left(\xi_i \frac{d\eta_k}{du_i}\right)\frac{d}{du_k}\right) + \sum_{i=1}^{n}\sum_{j=1}^{n}\left((\xi_i\eta_j\Gamma_{ji}^k)\frac{d}{du_k}\right)\right)$$

(and finally, factoring out the elements of the basis)

$$= \sum_{k=1}^{n}\left(\sum_{i=1}^{n}\left(\left(\xi_i \frac{d\eta_k}{du_i}\right)\right) + \sum_{i=1}^{n}\sum_{j=1}^{n}(\xi_i\eta_j\Gamma_{ji}^k)\right)\frac{d}{du_k}$$

we get the promised formula for $\nabla(\xi, \mathcal{V})$. In terms of a curve $\gamma$ that goes through the point $p$ at time $t_0$ with the tangent vector $\xi$, this is

$$\sum_{k=1}^{n}\left(\sum_{i=1}^{n}\left(\frac{d(\eta_k \circ \gamma)}{dt}\bigg|_{t_0}\right) + \sum_{i=1}^{n}\sum_{j=1}^{n}(\xi_i\eta_j(p)\Gamma_{ji}^k(p))\right)\frac{d}{du_k}\bigg|_p . \tag{C.6}$$

So we have a word, 'connection', and we know that it is not a meaningless one, because all we need are some $n^3$ functions, the '$\Gamma_{ij}^k$'s to specify one. (The official, undescriptive and even misleading name for the '$\Gamma_{ij}^k$'s is the *Christoffel symbols* – I prefer to use the more descriptive but less popular name *connection coefficients*, but even this does not sufficiently stress the fact that these are functions that can change as we move around the manifold.) We also know a connection is not an *a priori* useless thing, because if we have a curve with the right tangent vector, we use it and the connection to compute something.

But the real reason we care about Definition C.11 will not be seen for a few pages, that is, until we work throught the most important example. Along the way we will introduce some further terminology that will take us closer to our goal, but understanding Definition C.11 will be our main objective for the moment. The main idea is that connections will enable us bring vectors from one tangent space to another tangent space to compare them. In this way a connection is sort of like a set of pnuematic tubes that run between every point on the manifold, through which we can send and receive tangent vectors. As one might guess things can happen to the tangent vectors while in

transit. In particular, one can send a tangent vector around a closed loop, and it will not necessarily come back the same as it was when it started. This is not a defect of the system, but one of its strengths.

For such a complicated structure to be useful, we first need a fruitful way to compare vectors in a fixed tangent space. There are a number of other things we could define without this added structure, but I suspect that they would all be better motivated if we make everything concrete first, rather than afterwards. In light of this change of mood, we will close the current subsection and begin a new one now.

## Riemannian manifolds

**Definition C.12.** A *Riemannian manifold* is a pair, a smooth manifold $M$, together with a map $g$ defined on the manifold that associates to each point an inner product, that is,

$$g(p) = \langle \cdot, \cdot \rangle_p : T_pM \times T_pM \to \mathbf{R};$$

$g$ must satisfy the additional property that for any open set $U \subset M$ and any fixed $\mathcal{V}, \mathcal{W} \in \text{vect}(U)$ the function

$$\langle \mathcal{V}, \mathcal{W} \rangle : U \ni p \mapsto g(p)(\mathcal{V}_p, \mathcal{W}_p) = \langle \mathcal{V}_p, \mathcal{W}_p \rangle_p \in \mathbf{R}$$

is differentiable on $U$. Any $g$ satisfing all of these conditions is called a *smooth Riemannian metric*.

**Remark C.8.** The idea of a Riemannian metric is (as the name suggests) the heart of Riemannian geometry. This is what lets us compare vectors at a point: in accordance with our experience from Euclidean space, which as we have remarked the tangent space *is*, the *length* of a vector $\xi$ based at the point $p$ is

$$|\xi|_p = \sqrt{\langle \xi, \xi \rangle_p}. \tag{C.7}$$

The *angle* between two vectors $\xi$ and $\eta$ based at the point $p$ is

$$\cos^{-1}\left(\frac{\langle \xi, \eta \rangle_p}{|\xi|_p |\eta|_p}\right). \tag{C.8}$$

The difference from what we might be used to is that the metric can change as we move from place to place. This is what makes comparing vectors from different tangent spaces such a subtle problem.

The Riemannian metric makes available to us for the first time some concrete geometric content. In addition to making local comparisons, we can begin to move around in the manifold and talk, for example, about the *length of a curve* $\gamma : [a, b] \to M$ in analogy with our experience in Euclidean space (see Chapter 2) as being

$$\int_a^b \left| \frac{d}{dt}\gamma(t) \right| \, dt. \tag{C.9}$$

If we define the *distance* between two points in the manifold by $d(p, q) = \inf_\gamma \text{length}(\gamma)$ then we get a distance metric on the manifold, and the manifold therefore can be viewed as a metric space. (Note that Riemannian metrics and distance metrics are very, very different things!)

As we made explicit in the section on Algebraic Preliminaries, each inner product on a finite dimensional vector space is determined by a matrix. We will write the matrix associated with the inner product at the point $p$ as $\left(g_{ij}(p)\right)$ where the '$g_{ij}(p)$'s are determined by the inner products of basis vectors as in remark A.2. We write $(g_{ij})$ when we want to be mobile.

The inverse matrix often comes up in computations. It is traditional to write $(g_{ij})^{-1} = (g^{ij})$. Since these matrices are inverses, the sum $\sum_{i=1}^{n} g^{ij} g_{jk} = \delta_{ik}$.

We are getting very close to an explicit statement of the 'correct' way to compare tangent vectors from different tangent spaces; in fact, there is just one more definition we need before we can state our big theorem.

**Definition C.13.** For $U \subset M$ an open subset, if $\mathcal{V}, \mathcal{W} \in \text{vect}(U)$ we define their *Lie Bracket* or *commutator* $[\mathcal{V}, \mathcal{W}]$ to be the unique vector field such that

$$\forall p \in U : [\mathcal{V}, \mathcal{W}]|_p = \mathcal{V}|_p \circ \mathcal{W}|_p - \mathcal{W}|_p \circ V|_p.$$

**Remark C.9.** Note that in this and in the previous definition, the reason we talk about an open set $U$ is that we will want to use local vector fields a lot of the time.

**Theorem C.1 (Levi-Civita).** If $M$ is a Riemannian manifold then there exists a unique connection $\nabla^{\mathrm{LC}}$ for which all $\mathcal{U}, \mathcal{V}, \mathcal{W} \in \mathrm{vect}(M)$ satisfy

i. $\nabla^{\mathrm{LC}}(\mathcal{V}, \mathcal{W}) = \nabla^{\mathrm{LC}}(\mathcal{W}, \mathcal{V}) + [\mathcal{V}, \mathcal{W}]$

ii. $\mathcal{U}\langle \mathcal{V}, \mathcal{W}\rangle = \langle \nabla^{\mathrm{LC}}(\mathcal{U}, \mathcal{V}), \mathcal{W}\rangle + \langle \mathcal{V}, \nabla^{\mathrm{LC}}(\mathcal{U}, \mathcal{W})\rangle$.

**Remark C.10.** 'LC' stands of course for 'Levi-Civita'; $\nabla^{\mathrm{LC}}$ is called the *Levi-Civita connection for the Riemannian metric on* $M$. The two conditions say respectively that the Levi-Civita connection is *torsion-free* (in the sense that commutation is respected; this implies that the '$\Gamma^k_{ij}$'s depend on the metric in a particularly simple fashion, and are, as we will see, symmetric under exchange of $i$ and $j$) and that it is *compatible with the metric* in the sense that it behaves like a standard derivative of the metric (for example, if $v$ and $w$ are tangent vectors to a curve, $\frac{d\langle v,w\rangle}{dt} = \left\langle \frac{dv}{dt}, w\right\rangle + \left\langle v, \frac{dw}{dt}\right\rangle$).

*Proof of Theorem C.1.* Assuming such a connection $\nabla^{\mathrm{LC}}$ exists, we compute like mad (see Table C.1). Upon collecting like terms we have that

$$\begin{aligned}\langle \nabla^{\mathrm{LC}}(\mathcal{U}, \mathcal{V}), \mathcal{W}\rangle = \frac{1}{2}\big(&\mathcal{U}\langle \mathcal{V}, \mathcal{W}\rangle + \mathcal{V}\langle \mathcal{W}, \mathcal{U}\rangle - \mathcal{W}\langle \mathcal{U}, \mathcal{V}\rangle \\ &- \langle \mathcal{W}, [\mathcal{V}, \mathcal{U}]\rangle + \langle \mathcal{U}, [\mathcal{W}, \mathcal{V}]\rangle - \langle \mathcal{V}, [\mathcal{U}, \mathcal{W}]\rangle\big)\end{aligned} \tag{C.10}$$

which gives us the exact form of $\langle \nabla^{\mathrm{LC}}(\mathcal{U}, \mathcal{V}), \mathcal{W}\rangle$ and therefore fixes $\nabla^{\mathrm{LC}}(\mathcal{U}, \mathcal{V})$.

To get the form explicitly, we have to compute the '$\Gamma^k_{ij}$'s in terms of the metric; condition (i) of the theorem implies that

$$\nabla^{\mathrm{LC}}\left(\frac{d}{du_j}, \frac{d}{du_k}\right) = \nabla^{\mathrm{LC}}\left(\frac{d}{du_k}, \frac{d}{du_j}\right) + \left[\frac{d}{du_j}, \frac{d}{du_k}\right] \tag{C.11}$$

but $\left[\frac{d}{du_j}, \frac{d}{du_k}\right] = \frac{d}{du_j} \circ \frac{d}{du_k} - \frac{d}{du_k} \circ \frac{d}{du_j} = 0$ by equality of mixed partials*, so by definition (Equation C.5) we have $\Gamma^k_{ij} = \Gamma^k_{ji}$. Then Equation C.10 implies that

$$\left\langle \nabla^{\mathrm{LC}}\left(\frac{d}{du_i}, \frac{d}{du_j}\right), \frac{d}{du_k}\right\rangle = \frac{1}{2}\left(\frac{d}{du_i}\left\langle \frac{d}{du_j}, \frac{d}{du_k}\right\rangle + \frac{d}{du_j}\left\langle \frac{d}{du_k}, \frac{d}{du_i}\right\rangle\right.$$

*That is all this is, really.

$$
\begin{aligned}
& -\frac{d}{du_k}\left\langle \frac{d}{du_i}, \frac{d}{du_j} \right\rangle - \left\langle \frac{d}{du_k}, \left[ \frac{d}{du_j}, \frac{d}{du_i} \right] \right\rangle \\
& + \left\langle \frac{d}{du_i}, \left[ \frac{d}{du_k}, \frac{d}{du_j} \right] \right\rangle - \left\langle \frac{d}{du_j}, \left[ \frac{d}{du_i}, \frac{d}{du_k} \right] \right\rangle \Big) \\
= \; & \frac{1}{2}\left( \frac{d}{du_i}\left\langle \frac{d}{du_j}, \frac{d}{du_k} \right\rangle + \frac{d}{du_j}\left\langle \frac{d}{du_k}, \frac{d}{du_i} \right\rangle \right. \\
& \left. -\frac{d}{du_k}\left\langle \frac{d}{du_i}, \frac{d}{du_j} \right\rangle \right) \\
= \; & \frac{1}{2}\left( \frac{d}{du_i} g_{jk} + \frac{d}{du_j} g_{ki} - \frac{d}{du_k} g_{ij} \right) \qquad \text{(C.12)}
\end{aligned}
$$

But by the definition of the '$\Gamma^k_{ij}$'s and the properties of inner products, we also have

$$
\begin{aligned}
\left\langle \nabla^{\mathrm{LC}}\left( \frac{d}{du_i}, \frac{d}{du_j} \right), \frac{d}{du_k} \right\rangle &= \left\langle \sum_{i=1}^{n} \Gamma^i_{jk} \frac{d}{du_i}, \frac{d}{du_k} \right\rangle \\
&= \sum_{i=1}^{n} \left\langle \Gamma^i_{jk} \frac{d}{du_i}, \frac{d}{du_k} \right\rangle \\
&= \sum_{i=1}^{n} \Gamma^i_{jk} \left\langle \frac{d}{du_i}, \frac{d}{du_k} \right\rangle \\
&= \sum_{i=1}^{n} \Gamma^i_{jk} g_{ki} \qquad \text{(C.13)}
\end{aligned}
$$

Cleverly, we note that

$$
\sum_{k=1}^{n} g^{kl}\left( \sum_{i=1}^{n} \Gamma^i_{jk} g_{ki} \right) = \sum_{k=1}^{n}\sum_{i=1}^{n} g^{kl} g_{ki} \Gamma^i_{jk} = \sum_{k=1}^{n} \delta_{ik} \Gamma^i_{jk} = \Gamma^i_{jk}. \qquad \text{(C.14)}
$$

So combining everything we must have

$$
\Gamma^i_{jk} = \frac{1}{2}\sum_{j=1}^{n} g^{kj}\left( \frac{d}{du_i} g_{jk} + \frac{d}{du_j} g_{ki} - \frac{d}{du_k} g_{ij} \right) \qquad \text{(C.15)}
$$

On the other hand, these '$\Gamma^i_j k$'s specify a connection, and the reverse of the argument just given shows that this connection satisfies the conditions of the theorem. QEF

**Corollary C.1.** The connection coefficients for the Levi-Civita connection in $\mathbf{R}^n$ are all zero.

*Proof.* In Euclidean space the coefficients of the metric (the '$g_{ij}$'s) are all constant. Therefore in equation C.15 we are differentiating constants and summing. The result of this operation is always zero. QEF

$$
\begin{aligned}
\langle \nabla^{\mathrm{LC}}(u,v), w \rangle &= u\langle v, w\rangle - \langle v, \nabla^{\mathrm{LC}}(u,w)\rangle \\
&= u\langle v, w\rangle - \langle v, \nabla^{\mathrm{LC}}(w,u)\rangle - \langle v, [u,w]\rangle\rangle \\
&= u\langle v, w\rangle - w\langle v,u\rangle + \langle \nabla^{\mathrm{LC}}(w,v),u\rangle - \langle v,[u,w]\rangle\rangle \\
&= u\langle v, w\rangle - w\langle v,u\rangle + \langle \nabla^{\mathrm{LC}}(w,v),u\rangle + \langle [w,v],u)\rangle - \langle v,[u,w]\rangle\rangle \\
&= u\langle v, w\rangle - w\langle v,u\rangle + v\langle w,u\rangle - \langle w, \nabla^{\mathrm{LC}}(v,u)\rangle + \langle [w,v],u\rangle - \langle v,[u,w]\rangle\rangle \\
&= u\langle v, w\rangle - w\langle v,u\rangle + v\langle w,u\rangle - \langle w, \nabla^{\mathrm{LC}}(v,u)\rangle - \langle w,[v,u]\rangle + \langle [w,v],u\rangle - \langle v,[u,w]\rangle\rangle.
\end{aligned}
$$

Table C.1: Computing the form of the Levi-Civita connection

Having gone through the hard work of defining the 'right' connection, we can now begin to put our system to work. (We will then see why this connection is the right one.)

**Definition C.14.** Given a chart $(U, \varphi)$ and a smooth curve $\gamma : [a, b] \to U \subset M$ such that $U \supset \gamma$ we define the *derivative of a vector field* $\mathcal{V}$ *along* $\gamma$ in coordinates as follows: we write $\mathcal{V}(t) = \sum_{j=1}^{n} \xi_j(t) \frac{d\gamma}{du_j}|_{\gamma(t)}$ and then write

$$\nabla^{\mathrm{LC}}\left(\frac{d\gamma}{dt}, \mathcal{V}(t)\right) = \sum_{i=1}^{n}\left(\left(\left.\frac{dxi_i}{dt}\right|_{t_0} + \sum_{j=1}^{n}\sum_{k=1}^{n}(\Gamma^i_{jk} \circ \gamma)\xi_j(t_0)\left(\left.\frac{d\gamma_j}{dt}\right|_{t_0}\right)\right)\left.\frac{d\gamma}{du_i}\right|_{\gamma(t_0)}\right). \tag{C.16}$$

**Remark C.11.** The same formal definition works for other connections, in fact the definition is essentially the same, but since the connection coefficients are coming from the Levi-Civita connection, this derivative respects the metric and is torsion free.

**Definition C.15.** If $\gamma : (a, b) \to M$ is a path in $M$, we say that $\mathcal{V}$ is *parallel along* $\gamma$ if

$$\nabla^{\mathrm{LC}}\left(\frac{d\gamma}{dt}, \mathcal{V}(t)\right) = 0 \tag{C.17}$$

for all $t \in (a, b)$.

**Definition C.16.** We say a path $\gamma : (a, b) \to M$ is a *geodesic* if

$$\nabla^{\mathrm{LC}}\left(\frac{d\gamma}{dt}, \frac{d\gamma}{dt}\right) = 0 \tag{C.18}$$

for all $t \in (a, b)$, *i.e.* if the tangent vector to $\gamma$ is parallel along $\gamma$ on the entire interval on which $\gamma$ is defined.

**Remark C.12.** To write the equation for a geodesic in local coordinates, we set $\gamma_j = x_j \circ \gamma$ as above. Then our definition for the derivative of a vector field along a curve (Definition C.14) implies that Equation C.18 becomes

$$\sum_{i=1}^{n}\left(\left(\left.\frac{d^2xi_i}{dt^2}\right|_{t_0} + \sum_{j=1}^{n}\sum_{k=1}^{n}(\Gamma^i_{jk} \circ \gamma)\left(\left.\frac{d\gamma_j}{dt}\right|_{t_0}\right)\left(\left.\frac{d\gamma_j}{dt}\right|_{t_0}\right)\right)\left.\frac{d\gamma}{du_i}\right|_{\gamma(t_0)}\right) = 0. \tag{C.19}$$

We can rewrite this second order equation as a first order system, and after that, rewrite the condition of being a geodesic in terms of the condition of being an integral curve for a certain vector field.

To each chart $(U, \varphi)$ on $M$ we associate a chart $(Q, \psi)$ on $TM$ by putting $Q = \pi^{-1}(U)$ and

$$\psi(\xi) = (\varphi \circ \pi(\xi), \xi(u_1), \ldots, \xi(u_n)) \in \mathbf{R}^{2n} \tag{C.20}$$

on $Q$. We write $q(\xi) = \varphi \circ \pi(\xi) \in \mathbf{R}^n$ and $\dot{q}(\xi) = (\xi(u_1), \ldots, \xi(u_n)) \in \mathbf{R}^n$. Using this notation we have

$$\xi = \sum_{j=1}^{n} \dot{q}_j(\xi) \left.\frac{d}{du_j}\right|_{\pi(\xi)}. \tag{C.21}$$

The differential equation above can be rewritten as

$$\frac{dq_j}{dt} = \dot{q}_j \tag{C.22}$$

$$\frac{d\dot{q}_j}{dt} = -\sum_{j=1}^{n}\sum_{k=1}^{n}(\Gamma^i_{jk} \circ \pi)\dot{q}_j\dot{q}_k. \tag{C.23}$$

The solution to this system are integal curves of the vector field $\mathcal{G}$ defined on $Q$ by

$$\mathcal{G} = \sum_{i=1}^{n}\left(\dot{q}_j\frac{d}{dq_j} - \sum_{j=1}^{n}\sum_{k=1}^{n}(\Gamma^i_{jk} \circ \pi)\dot{q}_j\dot{q}_k\frac{d}{d\dot{q}_i}\right). \tag{C.24}$$

**Definition C.17.** Let $\varphi(t, \xi)$ denote the geodesic flow of the vector field $\mathcal{G}$ of the previous remark (*i.e.* the map that tames points in $M$ to the points in the direction given by $\mathcal{G}$).

Let

$$\gamma_\xi : [0, 1] \ni t \mapsto \pi \circ \varphi(t, \xi) \in M.$$

Let $T^1M$ denote

$$\{\xi \in TM : 1 \in \text{maximal interval on which } \gamma_\xi \text{ is defined}\}.$$

We define

$$\exp : T^1M \ni \xi \mapsto \gamma_\xi(1) \in M.$$

**Remark C.13.** Frequently the manifolds we work with in this thesis will be *complete*, that is, their geodesics will run on forever (although they may, as in the case of spheres, come back and trace over themselves again, or, as in the case of tori, come back and intersect themselves infinitely often). *In the case of complete manifolds,* exp *is defined on all of* $TM$.

We note that one sometimes sees the related definition

$$\exp t\cdot : T^1M \ni \xi \mapsto \gamma_\xi(t) \in M, \tag{C.25}$$

for example in the proof of Theorem 2.1.

## Differential forms

Recall from the section on algebraic preliminaries that the dual of a finite dimensional vector space is the set of linear maps from that vector space to the base field, and that it is isomorphic to the original vector space. Since tangent spaces are finite dimensional real vector spaces, it is very easy to talk about their duals, which are called cotangent spaces[†]. Just to point out exactly where things stand, tangent vectors are a special kind of linear maps from functions on the manifold to the real numbers – and now we have cotangent vectors which are all of the linear maps taking that set of maps into the real numbers! The basis of the cotangent space that is dual to the standard basis of the tangent space is denoted $\{du^i\}$.

**Definition C.18.** The *cotangent bundle* of a manifold is the union over $x$ in $M$ of all the the cotangent spaces.

If we wanted to, we could write this in the careful way we wrote the tangent bundle above. All of the same ideas apply. In particular, we can define sections of the cotangent bundle. We are especially interested in the smooth sections, which we give a special name.

[†]This name has even less to do with the cotangent function from trigonometry than tangent spaces have to do with the tangent function – which is, admittedly, something, but not a lot.

**Definition C.19.** A smooth $m$-section of the cotangent bundle (that is, a choice of $m$ vectors in each cotangent space that varies smoothly with respect to the smooth structure on the cotangent bundle) is called a *differential $m$-form* (this is usually just shortened to $m$-form). We extend this in a slightly odd way by say that smooth functions on the manifold are *zero forms*[‡]. The collection of all $m$-forms ($m \in 0, 1, \ldots$) is the set of *differential forms* (or sometime, just *forms*). After lumping them all together, we sort them back out again by saying a differential form has *degree* $m$ if it is a $m$-form.

The fundamental binary operation on differential forms is the $\wedge$ product ('wedge product'). This is defined by the action of differential 1-forms on tangent vectors and its important because it defines the action of differential $m$-forms for higher $m$ on lists of tangent vectors, *i.e.* on sections of the tangent bundle. (The key point is that the $m$-form is associated with the wedge product of all of the 1-forms that make it up.)

**Remark C.14.** The standard short-hand for lists of $m$ vectors is *$m$-vectors*.

If $\omega$ is a $m$-form and $\upsilon$ is a $p$-form, their wedge product $\omega \wedge \upsilon$ takes an $(m+p)$-vector $(\xi_1, \ldots, \xi_{m+p})$ to the number

$$\frac{1}{m!p!} \sum_{\sigma \in \mathfrak{S}^{m+p}} \operatorname{sign}(\sigma) \omega(\xi_{\sigma(1)}, \ldots, \xi_{\sigma(m)}) \upsilon(\xi_{\sigma(m+1)}, \ldots, \xi_{\sigma(m+p)}). \tag{C.26}$$

If $\omega$ and $\upsilon$ are *1-forms* this complicated expression reduces to

$$\sum_{\mathfrak{S}^2} \operatorname{sign}(\sigma) \omega(\xi_{\sigma(1)}) \upsilon(\xi_{\sigma(2)}) = \omega(\xi_1)\upsilon(\xi_2) - \omega(\xi_2)\upsilon(\xi_1); \tag{C.27}$$

In the case that one of the factors is a zero form, things get even easier since the wedge product reduces to standard multiplication.

In the case of a one form and a two form, the expression is almost as simple as it is for two one forms; and from here, various properties can be deduced[§] by induction.

[‡]Actually, I think that this might not be *so* odd; it might make sense for it to be standard practice to say that smooth functions are zero sections of any bundle

[§]Or, induced.

There are three fundamental unary operations on differential forms; their names are $\iota$, $d$, and $\delta$.

Actually, to be precise, $\iota$ is map defined from vector fields *into* the space of operators on differential forms. The definition is that $\iota(\mathcal{V})$ takes $m$-forms to $(m-1)$-forms that act by the following rule:

$$(\iota(\mathcal{V})\omega)(\xi_1, \ldots, \xi_{m-1}) = \omega(\mathcal{V}, \xi_1, \ldots, \xi_{m-1}).$$

The map $\iota$ is called the *substitution operator*. (At last, a nice, descriptive name! – the reason we use the *symbol* '$\iota$' is perhaps less clear at this point; the reason is that $\iota$ is associated with integration.)

The operator $d$ is called the *coboundary operator*; it is a map from $m$-forms to $(m+1)$-forms, and it is defined by these properties:

1. $d(\omega + \upsilon) = d\omega + d\upsilon$

2. $d(\omega \wedge \upsilon) = d\omega \wedge \upsilon + (-1)^{\text{degree}(\omega)} \wedge d\upsilon$

3. $dd\omega = 0$

4. for all zero forms $f$, $df = \sum_{i=1}^{n} \frac{df}{du_i} du_i$

The '$d$' appearing at the beginning of '$du_i$' is a special case of this '$d$'.

At this point we go on to define a couple of essential operations that have something to do with forms. *The following two definitions are almost impossible to keep straight, so pay attention*[¶].

**Definition C.20.** The *pushforward* of a map $\varphi : M \to N$ is a map $\varphi_* : TM \to TN$ defined so that so that if $\gamma$ is a curve in $M$ with tangent vector $\xi$ at time $t_0$, then $\varphi_*$ is the map that takes $\xi \in TM$ to

[¶] In the spirit of SOHCAHTOA, the acronym BOTCGNTTOFFEPF (Bottom On Tangents, Curve Gives New Tangent; Top On Forms, Form Eats Push Forward) may serve as a mneumonic tool to help the reader remember which one is which, and what they do.)

the vector in $TN$ that is tangent to the curve $\varphi(\gamma(t_0))$.

The map $\varphi_*$ is sometimes called the *differential of* $\varphi$ and written as $d\varphi$. One can explore the relationship of this '$d$' to the one above.

**Definition C.21.** The *pullback* of a differential form is defined whenever we have a smooth map $\varphi$ between two manifolds, say $\varphi : M \to N$. If $v$ is a form on $N$, then $\varphi^*(v)$ is a form on $M$ determined by

$$(\varphi^*(v))(\xi_1, \ldots, \xi_m) = v(\varphi_*\xi_1, \ldots, \varphi_*\xi_m).$$

Since have been talking about a *coboundary* operator, it might seem that we should have already at least mentioned the *boundary* operator. In fact, we have used this operator throughout the thesis, although we have not been terribly explicit about what we were doing. The boundary operator we are refering to just finds boundary of subsets in the manifold, in symbols, $\partial A = \bar{A} \setminus A^\circ$ for all $A \subset M$. It is a basic topological property that

$$\partial\partial A = \emptyset \tag{C.28}$$

for all subsets $A$. We are using the prefix 'co' approximately as we used it to talk about the cotangent bundle, *i.e.* we are talking about objects that are dual to one another in some sense. So far, we have defined the coboundary operator to act on the space of differential forms, which in turn act on the space of sections. We now use the definition of the action of differential forms on sections to define their action on domains. The way we let a differential $m$-form $\omega$ act on a $m$-dimensional domain $C$ is by integrating; we define $\int_\Omega \omega$ to be $\int_{\{p\in\Omega\}} \omega(\xi_1(c), \ldots, \xi_n(c))$, where $\{\xi_k(p)\}_{k=1}^n$ is the ordered basis for $T_p\Omega$.

The coboundary operator $d$ is dual to the boundary operator $\partial$ in the sense that

$$\int_{\partial\Omega} \omega = \int_\Omega d\omega. \tag{C.29}$$

This important equation has a name: it is called Stokes' Theorem. A nice proof of Stokes' Theorem is written down in [18]. We note that in the special case that $\Omega$ is the boundary of some set

$A$, C.28 implies that the left hand side of C.29 is zero. Hence, we deduce that the integral over a boundary of the coboundary of any form is zero.

Our last word on special operators applies to the operator $\delta$. It extremely interesting, and we can not get away without mentioning that it is extremely useful for talking about the shape and structure of manifolds, and that there is a dual operator that does the same thing for domains. But that is where we have to stop.

There are various inner products and norms defined on differential forms, and we close this section with a list of the most important ones.

**Definition C.22.** We say an $m$-form is *simple* if it can be written as a one-term sum.

We can define an inner product between simple forms $\omega = w_1 \wedge \ldots \wedge w_m$ and $v = v_1 \wedge \ldots \wedge v_m$ based at $p$ by

$$\langle\langle \omega, v \rangle\rangle = \sum_{\sigma \in \mathfrak{S}} \operatorname{sign}(\sigma) \prod_{k=1}^{m} \langle w_{\sigma(k)}, v_k \rangle_p. \tag{C.30}$$

(We will only use the double angle bracket notation in the appendix.)

The term on the right of Equation C.30 is clearly equal to

$$\sum_{\sigma \in \mathfrak{S}} \operatorname{sign}(\sigma^{-1}) \prod_{k=1}^{m} \langle w_k, v_{\sigma^{-1}(k)} \rangle_p,$$

and so our definition is symmetric. Linearity of the standard inner product on vectors extends the definition to all $m$-vectors. The norm induced by this inner product is called the *Riemannian norm*.

**Remark C.15.** Since we can easily take an $m$-vector and define a $m$-form (by taking the wedge product of all of the vectors in the list), we can use the above definition to define a product between $m$-forms and $m$-vectors, which we also denote by $\langle\langle \cdot, \cdot \rangle\rangle$.

**Definition C.23.** The *mass* of a differential $m$-form $\omega$ is

$$\operatorname{mass}(\omega) = \sup\{\langle\langle \omega, \Xi \rangle\rangle; \Xi \text{ is an } m-\text{vector, and } \operatorname{comass}(\Xi) \leq 1\}$$

where comass is about to be defined.

**Definition C.24.** The *comass* of a $m$-vector $\Xi$ is

$$\text{comass}(\Xi) = \sup\{\langle\langle \omega, \Xi \rangle\rangle; \omega \text{ is an } m-\text{form}, \xi \text{ is simple , and } |\omega| \leq 1\}$$

(here $|\cdot|$ denotes the Riemannian norm).

### Isometries

**Definition 7.1.** A map $\varphi$ from $M$ to $M$ is an *isometry* if for all $p \in M$, if $\xi, \eta \in T_pM$ then $g(\xi, \eta) = g(\varphi_*\xi, \varphi_*\eta)$.

We state without proof the fact that the set of isometries for a manifold form a group; this group is appropriately called the *isometry group*.

**Definition C.25.** The *quotient* of a manifold by its isometry group is the set obtained by identifying each point with the point(s) in its orbit(s) under the isometry group.

## D Analytic Preliminaries

**Charter** Review of the basic results of Analysis germane to our discussion.

### Measures

Note the similarities between the following definition and the definition of a topological space (see appendix on Topological Preliminaries).

**Definition D.1.** *Measureable space* This is a pair $(X, \mathcal{M})$ such that $\mathcal{M}$ is comprised of subsets of $X$ and has the further additional properties

i. $X \in \mathcal{M}$.

ii. The complement in $X$ of any $A \in \mathcal{M}$ is again in $\mathcal{M}$.

iii. countable unions of elements of $\mathcal{M}$ are again in $\mathcal{M}$.

If $\mathcal{M}$ satisfies all of these properties, it is called a *$\sigma$-algebra*. The elements of $\mathcal{M}$ are then the *measurable sets of $X$ with respect to $\mathcal{M}$* or just *measurable sets*.

**Definition D.2.** A *measure* is a function $\mu$ taking a $\sigma$-algebra $\mathcal{M}$ into the complex numbers $\mathbf{C}$ with the property that $\mu(\emptyset) = 0$, and that satisfies an additional criterion, namely that for all countable disjoint collections $\{A_i; A_i \in \mathcal{M}\}$,

$$\mu\left(\cup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} \mu(A_i).$$

Functions with this property are said to satisfy *countable additivity*.

**Remark D.1.** Reasonably, we say that such a function $\mu$ is a *real* measure if its image is contained in the reals. Slightly less reasonably, but rather, according to convention, we say that a measure $\mu$ is *positive* if its image lies in the interval $[0, \infty]$.

The definition of a positive measure is unreasonable for two reasons: the first is easy to catch, namely it might be better to call such measures *non-negative* rather than positive, because zero is not positive. The second reason is that even though we allow $\infty$ into the range of a positive measure, $\infty \notin \mathbf{C}$, so by the above definition for measure it would never be hit. We make the special dispensation that $\mu$ may assign $\infty$ as the measure of a set as long as $\mu$ is positive.

We put this all together into one main definition as follows.

**Definition D.3.** A *measure space* is a measurable space $(X, \mathcal{M})$ together with a measure $\mu$ defined on $\mathcal{M}$.

**Remark D.2.** The definition of a measurable space is frequently written out as a triple, $(X, \mathcal{M}, \mu)$, rather than as a pair $((X, \mathcal{M}), \mu)$. Per usual, if $S = (X, \mathcal{M}, \mu)$ is a measure space, $p \in S$ means $p \in X$ (and in particular, a map defined on $S$ is a map defined on $X$.).

The structure of maps on measure spaces are understood in terms of the measurable sets of the underlying $\sigma$-algebra.

**Definition D.4.** A mapping from a measure space $(X, \mathcal{M}, \mu)$ into a topological space $(Y, \tau)$ is *measurable* if the inverse image of every open set $U \in \tau$ is an element of $\mathcal{M}$, *i.e.*, is a measurable set.

**Remark D.3.** When talking about a measure space, we say that a set is $\mu$-measurable if it is in the underlying $\sigma$-algebra. The terms 'almost everwhere', 'almost all', or, more specifically, '$\mu$-almost all', '$\mu$-almost everywhere', etc. when used to describe some property of a measure space mean that the property holds at all points except some set of $\mu$-measure zero.

**Example.** A *simple function* on a measure space $S$ is a map taking $S$ into $[0, \infty) \subset \mathbf{C}$ that has only finitely many points in its range.

Since the range of a simple function $\rho$ defined on $S$ is finite, $S$ splits into a finite number of subsets $A_1, \ldots, A_n$ such that $\rho(A_1) = a_1, \ldots, \rho(A_n) = a_n$. We can therefore write

$$\rho = \sum_{i=1}^{n} a_i \chi_{A_i},$$

where the '$\chi$'s are *indicator functions*, defined in general by $\chi_A : S \to \{0, 1\}, p \mapsto 1$ if $p \in A$, $p \mapsto 0$ else.

A simple function $\rho$ is measurable if and only if all of the '$A_i$'s are measurable, since the inverse image of an open interval will be a union of some subset of the '$A_i$'s and so measurable if all of the '$A_i$'s are by item (iii) of the definition of a $\sigma$-algebra; on the other hand, if $A_1$, say, is not measurable, then the inverse image of some small open interval about $a_1$ is equal to $A_1$ and $\rho$ then not measurable.

(We can show that there is a sequence of simple functions that approximate any given measurable function if need be.)

## Abstract integration

Rudin [45] treats this very thoroughly; the reader is refered to him for most of the proofs.

**Definition D.5.** If $S = (X, \mathcal{M}, \mu)$ is a measure space, $E \in \mathcal{M}$ and $\rho = \sum_{i=1}^{n} a_i \chi_{A_i}$ is a measurable simple function on $S$, we define the *integral of $\rho$ over $E$ with respect to the measure $\mu$* by

$$\int_E \rho \, d\mu = \sum_{i=1}^{n} a_i \mu(A_i \cap E).$$

In general, if $f : S \to [0, \infty]$ is measurable, we define the *(Lebesgue) integral of $f$ over $E$ with respect to the measure $\mu$* by

$$\int_E f \, d\mu = \sup_{\substack{\rho \text{ simple}, \\ 0 \le \rho \le f}} \int_E \rho \, d\mu.$$

In the case of measurable simple functions, it is easy to see that the two definitions give the same result

We get all the standard properties we expect of integrals (*i.e.*, integration respects majorization, is linear, etc.). These things are fairly easy to see for simple functions (we use countable additivity as needed) and then they carry over to the rest of the measurable positive functions because we can approximate such functions pointwise from below by a sequence of simple functions (so the supremum in the definition of the integral is ). A proof that we can approximate measurable functions by simple functions in this manner is not at all difficult, but for our purposes a sketch will suffice: the idea is to approximate $f$ from below wherever its values lie in $[0, n]$ by a simple function whose accuracy of approximation depends on $n$. Wherever $f$ takes values greater than $n$, it is approximated by a step of size $n$. As $n$ grows, we specify a finer and finer approximation on a growing finite interval, and so we converge wherever $f$ takes finite values. If $f$ takes the value infinity at some point or on some interval, it is approximated there by a sequence of steps of size $n$.

We also get a number of new consequences that show the superiority of the Lebesgue integral to the Riemann integral.

**Theorem D.1 (Monotone Convergence).** Let $\{f_n\}$ be a sequence of measurable functions on a measure space $S = (X, \mathcal{M}, \mu)$ and suppose that

i. $0 \leq f_1(x) \leq \ldots \leq \infty$ for every $x \in S$.

ii. $f_n(x) \to \infty$ as $n \to \infty$ for every $x \in S$.

Then $f$ is measurable and $\int_S f_n \, d\mu \to \int_S f \, d\mu$.

**Theorem D.2 (Fatou's Lemma).** If $\{f_n : S \to [0, \infty]\}$ is a sequence of measurable functions on a measure space $S = (X, \mathcal{M}, \mu)$, then for each positive integer $n$ we have

$$\int_S \liminf_{n\to\infty} f_n \, d\mu \leq \liminf_{n\to\infty} \int_S f_n \, d\mu$$

We now extend the definition of integration to cover integration of complex functions. This is the general definition of the Lebesgue integral.

**Definition D.6.** The *Lebesgue integral* over any measurable set is defined by breaking the function into its positive real, negative real, positive imaginary, and negative imaginary parts (which then all give positive functions), and integrating each seprarately, then multiplying by $1, -1, i$, or $-i$ as appropriate and summing.

Associated with this is the class of 'integrable functions'.

**Definition D.7.** The space $L^1(\mu)$ is the set of functions defined on all of $S = (X, \mathcal{M}, \mu)$ with the property that

$$\int_S |f| \, d\mu < \infty.$$

**Theorem D.3 (Dominated Convergence).** Suppose that $\{f_n : S \to \mathbf{C}\}$ is a measurable sequence of functions on a measure space $S = (X, \mathcal{M}, \mu)$ with the property that $\lim_{n\to\infty} f_n(x)$ exists for every $x \in S$. We call this function $f(x)$. If there is a function $g \in L^1(\mu)$ such that for all positive integers $n$ and all $x \in S$ we have

$$|f_n(x)| \leq g(x)$$

then we conclude the following properties must hold for $f$:

1. $f \in L^1(\mu)$
2. $\lim_{n\to\infty} \int_S |f_n - f|\, d\mu = 0$
3. $\lim_{n\to\infty} \int_S f_n\, d\mu = \int_S f\, d\mu$.

Finally, we state one other related theorem:

**Theorem D.4 (Fubini's Theorem).** Let $(X, S, \mu)$ and $(Y, T, \lambda)$ be $\sigma$-finite measure spaces and let $f$ be an $(S \times T)$-measureable function on $X \times Y$.

- If $0 \leq f \leq \infty$ and if for all $x \in X$ and $y \in Y$ we have

$$\varphi(x) = \int_Y f_x\, d\lambda$$

and

$$\psi(x) = \int_X f^y\, d\mu$$

then $\varphi$ is $S$-measurable, $\psi$ is $T$-measurable, and

$$\int_X \varphi\, d\mu = \int_{X\times Y} f\, d(\mu \times \lambda) = \int_Y \varphi\, d\lambda$$

- If $f$ is complex and if

$$\varphi*(x) = \int_Y |f|_x\, d\lambda$$

and

$$\int_X \varphi*\, d\mu < \infty$$

then $f \in L^1(\mu \times \lambda)$

- If $f \in L^1(\mu \times \lambda)$, the $f_x \in L^1(\lambda)$ for almost all $x \in X$, $f^y \in L^1(\mu)$ for almost all $y \in Y$ and the functions $\varphi$ and $\psi$

## Lebesgue measure

**Definition D.8.** A *Borel measure* is a measure on open sets.

**Theorem D.5.** Up to a constant multiple, there is a unique translation invariant positive Borel measure on $\mathbf{R}^n$.

**Remark D.4.** This measure is called the *Lebesgue measure*. In general, an isometry invariant measure is called a *Harr measure*. Each of $\mathbf{S}^n$ and $\mathbf{H}^n$ has, again up to a constant multiple, a unique Harr measure.

**Remark D.5.** Note that the Harr measures are in some sort of abstract sense like the Levi-Civita connection. Both respect the basic geometrical structures of the spaces they are defined on.

## Miscellaneous

**Definition D.9.** The lim inf (lim sup) of a sequence of functions is...

**Definition D.10.** A function $f$ is *upper semi-continuous with respect to a metric* $\delta$, if

$$\delta(a_k, a) \to 0 \Rightarrow \limsup_{k\to\infty} f(a_k) \leq f(a).$$

**Definition D.11 (Alternative definition, see Rudin, p. 39).** A function $f$ on a manifold $M$ is *upper semi-continuous* if $\{x : f(x) < \alpha\}$ is open for every real $\alpha$.

**Definition D.12.** A function or form or whatever has *compact support* if the set on which it takes nonzero values is compact.

**Definition D.13.** A function from one metric space $(X)$ to another $(Y)$ is said to satisfy a Hölder condition of order $\alpha$ or to be *Hölder continuous* if there exist $M$ and $\alpha$ such that for all $x, y \in X$ we have $d_Y(x, y) < M(d_X(x, y))^\alpha$.

**Definition D.14.** A function is *Lipschitz* if the $\alpha$ in Definition D.13 is equal to one.

**Definition D.15.** A function is *Hölder contiuously differentiable* or $C^{1,\alpha}$ if is differentiable and the differentiated function satisfies a Hölder condition of order $\alpha$.

**Definition D.16.** A *semi-norm* is a real valued function $p(x)$ defined on a vector space such that

i. $0 \leq p(x) < \infty$,

ii. $p(x, y) \leq p(x) + p(y)$,

iii. $p(ax) = |a|p(x)$.

**Definition D.17.** A function is *real analytic* in a neighborhood of $p$ if there is a convergent power series with real coefficients with center $p$ such that at every point in the neighborhood the value of the function and the sum of the power series coincide. (Complex analytic functions are defined similarly.)

# E Variational Calculus

**Charter.** We should understand how to find extrema for functionals defined on a set of geometric objects.

We won't be able to fully deal with this charter, but we will do what we can. We begin with a definition that has little or nothing to do with variational calculus.

**Definition E.1.** The *second fundamenatal form* of an $n$-dimensional manifold $M$ is defined in terms of local coordinates at a point $p \in M$ by using the fact that by embedding $M$ in some higher-dimensional $\mathbf{R}^N$, we may view $M$ locally as a graph of some function $f_p : T_pM \to \mathbf{R}$, where at each

point $\mathbf{R}$ is viewed as a line in the direction of some normal vector to $M$ at $p$. Specifically, we put

$$\mathbf{Sec}_p(M) = \begin{pmatrix} \frac{\partial^2 f_p}{\partial^2 x_1}\Big|_p & \cdots & \frac{\partial^2 f_p}{\partial^2 x_1 \partial^2 x_m}\Big|_p \\ \frac{\partial^2 f_p}{\partial x_n \partial x_1}\Big|_p & \cdots & \frac{\partial^2 f_p}{\partial^2 x_n}\Big|_p \end{pmatrix} \tag{E.31}$$

where $x_n, \ldots, x_n$ are coordinates for $T_pM$. The matrix $\mathbf{Sec}_p(M)$ defines a bilinear form on $T_pM$, which we call by the same name.

**Remark E.1.** Since $\mathbf{Sec}_p(M)$ is symmetric, we can choose a basis for $T_pM$ so that it becomes diagonal (see for example [20, page 266], and think about the geometrical content of the Corollary there). The numbers on the diagonal are called the *principal curvatures of $M$ at $p$* and are traditionally labeled $\kappa_1, \ldots, \kappa_n$.

**Definition E.2.** The *mean curvature of $M$ at $p$* is defined to be

$$H = \text{trace}(\mathbf{Sec}_p(M)).$$

The name 'mean curvature' might make more sense of course if $H$ was defined to be $\text{trace}(\mathbf{Sec}_p(M))$; however, several nice equalities depend our definition.

**Definition E.3.** Given a smooth, compactly supported vectorfield $\mathcal{V}$ defined on $M$ *first variation of area for a manifold with respect to* $\mathcal{V}$ is defined to be

$$\delta^1(M) = \frac{d}{dt}\Big|_{t=0} \text{area}(\text{M} + \text{t}\mathcal{V}),$$

where $M + t\mathcal{V}$ means the geodesic flow at time $t$ of points in $M$ in the directions given by $\mathcal{V}$.

The first variation of area measures the infinitesimal change in area due to an infinitesimal change in the shape of the manifold.

**Theorem E.1.** The first variation of area is given by integrating against mean curvature as follows:

$$\delta^1(M) = -\int_M \mathcal{V} \cdot H\nu,$$

where $\nu$ is a unit normal to $M$

We need a simple lemma.

**Theorem E.1.** Changing the radius of a circle of radius $r = 1/\kappa$ by $dr$ changes the arclength of an infinitesimal sector from $ds$ to $(1 - \kappa dr)ds$.

*Proof.* Putting the new radius equal to $r' = 1/k - dr$ and the length of the new sector equal to $(ds)'$, we need to prove that $\frac{r'}{r} = \frac{(ds)'}{ds}$. But $ds = rd\theta$, so $(ds)' = r'd\theta$. QEF

*Proof of Theorem E.1.* Since integration is linear, we can decompose $\mathcal{V}$ into normal and tangential components, and integrate each separately. In the case of a purely tangential variation, the surface does not change area, so the theorem is correct. In the case of a purely normal variation, we may write $\mathcal{V} = V\nu$; then, by refering the the preceeding lemma to see what happens in each direction, we find that an infinitesimal area $du_1 \wedge \ldots \wedge$ is distorted to

$$(1 - V\kappa_1)du_1 \wedge \ldots \wedge (1 - V\kappa_n)du_n, \tag{E.32}$$

where the '$\kappa_i$'s are the principal curvatures. Equation E.32 is equal to

$$(1 - V\nu \cdot H\nu)du_1 \wedge \ldots \wedge \tag{E.33}$$

*i.e.*

$$(1 - \mathcal{V} \cdot H\nu)du_1 \wedge \ldots u_n \wedge . \tag{E.34}$$

The initial rate of change in area is measured by integrating this over the manifold and then subtracting off the integral of $du_1 \wedge \ldots u_n \wedge$ over the manifold. The theorem follows. QEF

With the idea of a variation now in mind, we might, if we had time, go on to prove lots of things. For example, geodesics can be studied from the variational viewpoint. However, we don't have time for that.

The main thing we are interested in showing is that $H = d(Area)/d(Volume)$; we use the result of Theorem E.1, and state this as a proposition.

**Theorem E.1.** The mean curvature of a surface $S$ at a point is given by the derivative of area with respect to volume $d(Area)/d(Volume)$.

*Proof.* Since we are concerned with the behavior at a point, we can assume that the change in volume comes from a variation vector field that is defined on an infinisimal piece of area, and so can be considered constant. From Theorem E.1, we then have $dA/dt = H \int_S f$. Since everything is inifintesimal, we have $dV/dt = \int_S f$. The chain rule $dA/dV = (dA/dt)(dt/dV) = (dA/dt)(dV/dt)$ then finishes the proof. QEF

This proposition means that for our problem, we can think of mean curvature as an exchange rate (how much area is obtained for a certain amount of volume, or vice versa). A little thought then shows that the each of the surfaces separating two given components of a minimizer for the least-area problem with volume constraints have *globally* constant mean curvature. Of course, as with the standard double bubble, different pieces of surface may have different curvatures, because as we showed at the end of Chapter 2, curvature is proportional to pressure difference.

The ideas behind the following two definitions are undercurrents of the entire thesis:

**Definition E.4.** A surface is *stable* for the least-area problem if small variations do not decrease area.

**Definition E.5.** A surface is in *equilibrium* for the least-area problem if for any variation that fixes volumes, the first variation of area is zero.

This has been a very quick and incomplete introduction to the subject of variational calculus, giving us only the bare minimum of what we need for this thesis. There are many places to read more; [?] is good for further applications to area-minimization and geometric measure theory. In particular, there (in Part B) we find a very general and elegant description of the category of variational problems – which again, there is not time to talk about here.

| $\mathbf{S}^n$ | $n$-dimensional Spherical space |
| $\mathbf{H}^n$ | $n$-dimensional Hyperbolic space |
| $\mathbf{D}_p(r)$ | a disk of radius $r$ centered at $p$ |
| $B$ | a double bubble |
| $I$ | an isoperimetric profile |
| $\mathit{\Pi}$ | a two-volume least-area function |
| $\mathbf{G}^n$ | Gauss space |
| $Y$ | the standard partition of $\mathbf{G}^n$ into three equal pieces |
| $\mathbf{T}^2$ | a two-torus |
| $\mathbf{T}^3$ | a three-torus |
| $\Theta$ | a standard double bubble |
| $\Xi$ | a double band |
| $\Phi$ | a band lens |
| O | an octagon square |

*the characters of the appendix*

| | |
|---|---|
| $X$ | a set of points |
| $\tau$ | a topology |
| $M$ | a manifold |
| $p$ | a point in $M$ |
| $T_pM$ | the tangent space to $M$ at $p$ |
| $f$ | a differentiable map |
| $\mathcal{M}$ | a $\sigma$-algebra |

*Also necessary throughout are various numbers, unary and binary operators, delimiters, etc.*

The play has been performed in its entirity only once, in the Great Oklahoma Theater, where it was directed by Joseph K. (see [26]). That production included a cast of thousands. An abriged version is to be presented in the Soo Bong Chae Memorial Auditorium, May 6, 2002.

# Index of notational conventions used in this thesis

## Euclidean space

Many authors (Dubrovin *et al.* [11] for example) use a notation such as $\mathbf{E}^n$ for what I am calling $\mathbf{R}^n$, and they write their definitions in terms of the structure of the isometry group. However, in one of the more interesting turns of mathematical fate not treated it this thesis due to time constraints, we can *recover* the isometry group structure from the geometrical/vector space definition.

## Subscripts

Whenever possible, I avoid them and write things out using parentheses. Exceptions include a finite enumerated set, a countable enumerated set, and an uncountable set indexed by a real parameter,

and vector spaces associated with points on a manifold ($T_pM$, $\mathcal{N}_pM$, etc.)

This results in a non-standard notation for connections and derivations.

## Volumes and Regions

We denote a volume by a lower case letter, and a given region containing the volume by the corresponding upper case letter. For example, if we are considering a double bubble containing volumes $v$ and $w$ in $\mathbf{S}^3$ we let $u = |\mathbf{S}^3| - v - w$ be the volume of '$U$', the complement of the double bubble. The space has then been divided into three regions, $U, V$ and $W$. Similarly with other compact spaces. For non-compact spaces, we typically refer to the complement of a bubble cluster as *the exterior*.

Note that the space itself does not have to follow the casing rule, e.g. as in this paragraph we will use $\mathbf{S}^3$ to denote the unit radius three-sphere, and $|\mathbf{S}^3|$ to denote its volume.

Finally, we note that if we start with $V$ (an old-style '$U$') and then go to $W$, it is only fitting to have the $m^{\text{th}}$ volume be $V^m$.

## Proofs

QEF stands for *quad erat faciendum* which translates as 'what was to be done'. (QED stands for *quad erat demonstratum*, 'what was to be demonstrated'.) Both used to be used, and were even found interspersed in the same document sometimes. One text that used both is Galileo's *Dialogs Concerning Two New Sciences* [15]. I use QEF to mark the end of proofs first as an homage to that book, and, secondly, because I feel that that if the thesis demonstrates anything, it does so as a whole, and certainly not as frequently as after every proof.

## Technical details.

The final form of this thesis was composed using *xemacs*, LaTeX, *dvips*, and *xmodmap* on a Hewlett-Packard Pavillion 6330 running *Mandrake Linux 8* together with a keyboard from Kinesis Corporation. The line figures were produced using the *pstricks* package for LaTeX, except for the various conjectured minimizers appearing in Figure 7.1 which were drawn by *Surface Evolver*, and for a few which were drawn by hand.

Raytraced pictures of the tiled Euclidean plane and of the sphere appearing in Chapter 1 do so with the permission of their creators (in theory). The screenshot of *Asteroids* was taken with *xv* and edited slightly with the *GIMP*.

The phase diagrams in Chapter 6 were produced with *Mathematica*. The phase diagram in Chapter 7 was produced using *Surface Evolver*, *perl*, *GNUPlot*, and the *GIMP*. Computing the data for this phase plot in *Surface Evolver* took about 8 hours on 26 Dell PCs running in parallel.

**Typeface.** The text of this thesis is set in the "Charter" font available in standard LaTeX. Not only is this font nice and readible, but its name makes it fit nicely into one of the major themes of the thesis.
